 Birch, new Weeping, 525
 Birches and Aspens, 284
 Bird Cherry, 181
 Birds in the Botanical Gardens, 529
 Blackbirds, 343
 Blanc mange and Apricots, 39
 Blind, flowers for the, 41
 Blomus iscalinus, 512
 Blue gum tree, the, 32, 42
 Blyde's flower scissors, 215
 Boldoa fragrans, 410
 Bonamy's Weeping Birch, 525
 Books on plants, old, 175
 Boots, wet, 351
 Borders, flowers in out-door, 422
 Botanical Alpine Club, Scottish, 38, 422
 Botanical Gardens, birds in, 529
 Botanical names, reform in, 312
 Botanic Gardens, Edinburgh, addition to the, 589; early, 528; Hull, proposed change in, 287; Sydney, plants for, 168
 Botanic Society, Anniversary Meeting of the Royal, 112
 Botanists, directory of, 464
 Botany, Brown's Manual of, 15; for the young, 355
 Botryanthus pallens, 512
 Bouzaivillea, culture of, 294
 Bonnevards, the Vienna, 492
 Bouquets, arrangement of, 228; hand, 471; last of the season, 109
 Box edgings, 324
 Bramble, Parsley-leaved, 343
 Branch falling, 53
 Brantingham Thorpe, 291
 Brassica tribe in London market gardens, the, 349
 Brava geminiflora, 92, 146
 Breakfast-table, vases for, 223
 Briar, Sweet, fields of, 380
 Broccoli, Christie's Self-protecting, 437, 462; culture of, 34
 Bromeliaceous plants, 496
 Browallia elata, 496
 Brownea coccinea at Kew, 442
 Brugmansia sanguinea, 168

Brussels Sprouts, 418
 Bryanopsis laciniosa, 193
 Bryant, addition to Victoria Park made by, 190
 Bryony, 79
 Buckthorn, Sea, 232
 Bulb beds during frost, 516
 Bull Palm, the, 558
 Burghley Gardens, 27
 Butter-nut, raising, 548
 Button-hole bouquets and coat flowers, 372

C.

Cabbage, Cattell's Reliance, 117; large head of, 584; sprouts, 58; the Ker-guelen, 14
 Caladiums, wintering, 363
 Calanthes at Drumlanrig, 402
 Calceolarias, bedding, 320; shrubby, 415
 Calcutta Botanic Gardens, the, 512
 Californian woods, 382
 Calville Apple at Barham Court, 442
 Camellias, renovating neglected, 254; unhealthy, 538
 Camomile, culture of, 392
 Campanula Barrelieri, 192; hederacea, 221; Portenschlagiana, 100; Rainieri, 59; Smithi, 79
 Camphor, effect upon vegetation, 11, 296
 Campidium flicifolium, 593
 Cannas, free-flowering, 494
 Cannell's system of heating, 462
 Cantharidopho, 577
 Caoutchouc, extended use of, 492
 Carludovicia humilis, 429
 Carnation, new pink-coloured perpetual, 389
 Carnations, layering, 36; tree, 446
 Carnivorous plants, 210; the so-called, 288
 Carpets, the two, 399
 Carrot jam, 164
 Cassia corymbosa, 563
 Castanea corysophylla, 518
 Catalpa, the, 92, 132, 428; durability of the, 232
 Caterpillars, ravages upon Pine forests by, 238
 Cattleya gigas, 422
 Cauldrons for dry weather, 324; market garden, 309; the Herefordshire Dwarf, 371; Veitch's self-protecting, 437, 483
 Causton Manor, 400
 Ceanothus, 428
 Celery, 488; best varieties of, 490; culture round London, 116; Fungus affecting, 584; in cold countries, keeping, 629; Major Clarke's Red, 490; Sulham prize, 538
 Celosia Hutcheonii, 222; pyramidalis, 369, 499, 513
 Cemeteries, Mr. J. Smith on, 575
 Centaurea pascuina, 194
 Cerasus persicifolia, 131
 Cereis siliquastrum, 53
 Cereus speciosissimus, 10
 Chamerops humilis, male, 517
 Change of climate in Scotland, 233
 Chanterelles, the, 488
 Chartometer, Morris's, 528
 Chelone barbata autwepensis, 98
 Chelsea Botanic Garden, the, 388
 Cherries, market, 219; Frogmore Late Biggarean, 364; Jock-o-sot, 343; Orchard, German, 451; Bird, 181
 Cherry trees killed by sunstroke, 244
 Chestnuts, 366; harvest of, in the Apennines, 493
 Chickens, predatory, 140
 Chinese gardening, 200, 215
 Christmas decorations, 532, 559
 Chrysanthemums, 287; for table decoration, 472; in China, liquor distilled from, 532; at the Crystal Palace, 442; culture of, 424, 536; show of, at Stoke Newington, 186; in the Temple Gardens, 382

Cistus tauricus, 506
 Clapham Common improvements, 557
 Cleaning statuary, vases, &c., 170
 Clematis aethusefolia, 423; cirrhosa, 425; for pillars, 98; winter flowering, 462
 Climate in Scotland, change of, 233
 Climbers, new hardy, 583; conservatory, 119; stove, 100
 Climbing trees, method of, 573
 Cloche protector, a simple, 280
 Currants, the best, 220
 Clubbing, 324, 371
 Coal, wet, 355; impurity in, 475
 Cochlostema Jacobianum, 413
 Cockscomb, large, 170; pyramidal, 360, 499, 513
 Coffee as a disinfectant, 39
 Colchicum autumnale, 247; toxic action exercised by, 288; perishing, 24; singular properties of, 446
 Colons Duchess of Edinburgh, 233
 Colorado Potato beetle, 482
 Colorado, flora of, 262
 Colours of flowers, 446, 497, 539
 Conifer insects, 325
 Conifers at Beaufort, 377; effects of geological position on, 7; for Britain, the best, 333, 373; manuring, 351; of Italy, 28; raising from seed, 328
 Conservatories, wooden, 435
 Convolvulus soldanella, 366
 Cool foliage plants, 197
 Cool greenhouses, plants for, 197
 Cool Orchids, the best, 254
 Cordyline australis, 2
 Cork, indestructibility of, 328
 Corylopsis spicata, 503
 Cottage garden societies, 192
 Cottage in Kensington Gardens, 297
 Cottager's Kale, 89
 Cotoneaster Simandouii, 450
 Cotown Garden, 16; fruits in, 92, 238; foreign fruits in, 586; necessity for improving, 312; roofing, 215; winter and spring flowers in, 311
 Covent Garden Theatre, living plants at, 238
 Cowan's system of heating, Mr., 142
 Cow Parsnip-leaved Montagnia, 145
 Crab tree, a large, 111
 Cranberries, 580; New Jersey, 92; new Andean, 206
 Cranberry culture, 129
 Crassula Saxifraga, 71
 Creepers, true, 517, 539
 Crinum asiaticum, 71; Moorei, 248
 rose-coloured variety of, 163
 Crocus odoratus, 470
 Crocuses, autumn, 340
 Cromwell House, 334
 Crops in Devon, 9; shelter for, 418
 Crosses, 569; and wreaths, floral, 514
 Crowbar, a plea for the, 255
 Crown Imperials, 423
 Crystal Palace, flower beds at, 461
 decay and spoliation of gardens at, 142, 214

 Culture of Cypripedium, 43; of Potatoes, 347; of the great Water Lily, 169; of the Ivy Harebell, 221; of Tropaeolum polyphyllum, 21; of Vegetable Marrow, 180
 Cupressus Lawsoniana, 425
 Currant-bush in Elm tree, 388
 Cuttings, fruit tree, 343
 Cyanophyllum, propagation of, 149
 Cyas revoluta, 217
 Cyclobothra lutea, 215
 Cydonia japonica for hedges, 156
 Cymbidium giganteum, 532
 Cyresses, 425
 Cypripediums, propagation of, 43, 67; caudatum, 69; spectabile, 424
 Cytisus laburnum serotinum, 32

THE GARDEN INDEX.

vii

D.

Date Plum, the, 74, 556
 Dacrydium Franklini, 462
 Daugstein, gardens at, 203
 Dapone Fortunoi, 377
 Durlingtonia californica, 432
 Durwian philosopher, a, 163
 Dasylyrium acrotrichum, 262
 Davallia Mooreana, 464
 Duke of Buccleuch (grape), 565
 Dead-walls, draping, 217
 Decoration, a grumble about, 380;
 Russian table, 190; Christmas, 532,
 559; dinner table, 101, 118, 170, 241,
 266; sweet-scented plants for, 488
 Dessert, arrangement of fruit for, 267
 Deutzias, 131; scabra, 132
 Dianella tasmanica, 10
 Dinner-table decoration, 101, 148, 170,
 241, 266
 Diospyros Virginiana, 74
 Dipladenia amabilis, 190
 Diplopappus chrysophylla, 421, 497,
 516, 539
 Disa grandiflora, 68, 118; culture of,
 317
 Disraeli and gardening, 238
 Dolicholaba tubifera, 197
 Double Scarlet Thorn, haws on, 506
 Douglas Fir or Oregon Pine, the, 359
 Drapers' Company, garden of the, 20,
 103, 348
 Drapers' Garden, flower show at the, 66
 Drainage and watering of pot plants, 361,
 254
 Draining, 349
 Dreer's improved Lima Beans, 529
 Duckweed, fruiting, 213
 Dutch bulbs, 190
 Dwarfing trees, 99
 Dyspepsia, digging a cure for, 75

E.

Early May Potato, 392
 Eastwell Park, 478
 Eating berries of Rhamnus croceus, 32
 Echeverias, 10
 Echium vulgare, 446
 Edelweiss, accident whilst searching for
 the Alpine, 238
 Edging plant, new, 320; silvery, 270,
 298; Parsley, 79
 Edinburgh Botanical Club, 38
 Effect of late rains in Devonshire, 9
 Egypt, Bamboos in, 181
 Elder, rose-flowered, 7; under diffi-
 culties, 495
 Elms, branch-shedding in, 132
 Emigrants, a hint to intending, 530
 Engadine, flowers in the, 47
 English, the, in the natural parks of
 Colorado, 371
 Epidendrum piliferum, 445
 Epiphyllum leucobotrys, 535
 Epiphyllums, grafting, 294; treatment
 of, 515
 Eragrostis elegans, 341
 Ericaceous plants, 141
 Erica Mackayana, 335
 Erpeton reniformis, 222
 Eryngiums, new, 335
 Espalier fruit trees, 243, 389
 Eucalyptus amygdalica, great height
 of, 589; cordata at Balmuto, 66, 156,
 168; globulus, 32, 42
 Encharis americana, 168
 Euphorbia, 557
 Evergreens, transplanting, 526; flower-
 ing on a lawn, 498; when to prune,
 351; winter bedding, 517; mottoes in,
 569
 Evening Primroses, 196
 Exogonium purga, 360, 517

F.

Farringdon Market, proposed rebuilding
 of, 2
 Feathery Tamarisk, 252
 Fences, Gooseberry, 54; Laburnum, 32
 Fern cases, 534
 Fern-leaved Campsidium, 593
 Fern, a new gold, 495
 Ferns, 368; best British, 79; compara-
 tive rate of growth of tree, 216; Dr.
 Boswell Syme on, 512; from spores,
 317, 384; greenly on, 317; in parks,
 496; London, 6
 Fertile admixture of soils, 571
 Fertilisation, insect, 208, 422
 Festuca dives, 580
 Fibre-yielding plants, 395
 Ficarias, 47
 Figs, casting fruit of, 54; Kentish
 standard, 316
 Fig orchards, 220
 Filbert culture, 578
 Filling vases, materials for, 221

Firs and Pines, 156
 Fir, the Silver, 182
 Fir tree, the term, 526
 Flamingo plant, the, 337
 Flavouring, leaves for, 39
 Flax, new substitute for, 39
 Flora of Africa, Dr. Schweinfurth's col-
 lection of, 238
 Flora of Colorado, the, 262
 Floral decorations at Tunbridge Wells,
 41; at funerals, 332, 396
 Flore de Serres, Van Houtte's, 263, 367,
 460
 Flower-bed, a large, 216; an effective,
 495
 Flower-beds at Crystal Palace, 461
 Flower Farms of Morocco, 189
 Flower gardening at Stukely Hall, 470;
 in Hyde Park, 184
 Flower, Indian garland, 193; markets
 in Paris, new, 168; mission, 433;
 painting, 507
 Flowers and children, 316; at funerals,
 332, 396; autumnal, 349; baskets and
 vases of, 299; colours of, 416, 497, 539;
 curious artificial colouring of, 354;
 drying white, 25; effect of ammonia
 on the colours of, 412; fertilisation
 the cause of brilliancy in, 422;
 florists', 585; for dry borders, 6; for
 London balconies, 492; for the blind,
 41; from Piesse and Lubins' flower
 Farms, 580; gumming, 119; hanging
 basket of cut, 529; hardy, at Bitton,
 404; how to preserve cut, 299, 102;
 how we acquired a taste for, 139; in
 Hyacinth glasses, 341; in Hyde Park
 and Kensington Gardens, 145; in the
 Isle of Wight, 511, 576; not preserved
 by sal ammonia, 462; on lawns, 174;
 state of hardy, 118; simple vase of, 8;
 sweet scented, 488; wild Welsh, 5;
 wiring, 119
 Blue-beated Cucumber-pit, 371
 Foliage, coloured, 328
 Food, green, for Arctic expeditions, 538;
 treatise on, 75
 Forage plants, 393
 Forcing Seakale, 57, 276, 488; Straw-
 berries, 147; the Lily of the Valley, 408
 Forest, a buried, 481
 Forest trees, pruning, 107; English, 527
 Formalism and foliage, 11
 Fortune's, Saxifrage, 470
 Fota, Bamboos, &c., at, 73
 Fourcroyas, 430
 Foxgloves, 126
 France, flowers in, 404; teaching of
 horticulture in, 557
 Free Gardeners, Edinburgh Lodge of,
 532
 French Bean, 150; Flageolet, 462;
 select, 151
 Fruit and grain crop, near Mentone, 352
 Fruit and vegetable food, 185
 Fruit crops, English, 81, 92, 110; in
 Rosecommon, 179; Scotch, 109; Amer-
 ican, 86; culture, the Hoolbreuk sys-
 tem, 364; eating, 164; growing for
 market, 203, 218; for dessert,
 standard of quality, 263; for dessert,
 arrangement of, 192, 267, 341, 405; in
 a copper kettle, 552; in Gascony, 288;
 International Exhibition of, 422; in
 tin cans, 164; positions for hardy,
 570; ladders for picking, 239; of
 Stephanotis floribunda, 467; prices
 of, 239; report, American Pomolo-
 gical Society's, 291; rooms, orna-
 mental, 520
 Fruit drying, successful mode of, 114;
 the Alden process of drying, 537
 Fruit-houses, tropical, 415
 Fruit trees, cultivating, 474; low espal-
 ier, 243, 389; mulching, 474; pruning
 newly-planted, 263; to prevent split-
 ting in, 495; with low branches, 397;
 walls, wiring, 578; exhaustion of, 26
 Fruiterers' Company, dinner, 369
 Fruiting Duckweed (see Nertera)
 Fruits and vegetables, certificated, 552;
 tropical, 415; thinning blossoms of,
 364; bush, 147, 545; continental, 190;
 early distribution of, 526; foreign,
 in Covent Garden, 586; select, 524
 Fuchsia procumbens, 126, 363; Ricar-
 toni, 320; seed, 71
 Fuchsias, culture of, 31; in Ireland,
 196; in Isle of Man, 222
 Fungi, exhibition of, at Munich, 422; at
 Rothamsted, 233; growth of, 489;
 root, 548; show of, at Aberdeen, 310;
 show of, at South Kensington, 310; the
 Peziza class of, 539; at South Ken-
 sington, 336

G.

Game cover, 229
 Garden, Algerian, 447; Drapers' Com-
 pany's, 20, 103, 320, 348
 Gardeners, alleged degeneracy in
 young, 382

Gardeners' Benevolent Institution, 102,
 163, 188, 489
 Gardeners, Edinburgh Lodge of Free,
 532
 Gardener's friend, 318
 Gardeners' lamps, 507
 Gardener's Paradise, the Western States
 not a, 188

MR. ROBERT MARNOCK.

THE accompanying portrait is that of MR. ROBERT MARNOCK, a gentleman possessing a world-wide reputation as a landscape gardener. MR. MARNOCK'S professional career may be said to have commenced with the laying out of the Sheffield Botanical Gardens about the year 1837. His success in that case led to his being appointed by the Royal Botanic Society to form their new garden in the Regent's Park, and of the happy manner in which that work has been executed it is unnecessary now to speak. It so clearly bore the impress of a master mind in the art of landscape gardening, that from that time MR. MARNOCK ranked as one of the leading men in his profession. In MR. MARNOCK'S case the artist and practical landscape gardener have been so happily combined, that, in the numerous works executed under his direction it would be difficult to find one in which the highest principles of the art are not well shown. The same breadth of treatment, grace of outline, and easy and natural undulations which characterise the Regent's Park Gardens may be traced throughout most of his other works. In selecting a few from the many places either laid out or renovated by him, it may be sufficient to mention one or two of the more important, such as Warwick Castle, Hagley Hall, Draycott, Rood Ashton, Oak Lodge, Kensington; Hall Place, Tonbridge; Berry Hill and Park Place, Bucks; Greenlands, Henley-on-Thames; Wimbledon House, Surrey; Rousdon, Devon; Possingworth, Sussex; Eynsham Hall, Oxon; Wadhurst Park, Sussex, and others too numerous to be here specified. In 1853-54 he laid out the grounds of the villa San Donato, near Florence, for Prince Demidoff. In addition to many contributions to the horticultural and botanical press, he was for several years horticultural Editor of the "Gardeners' and Farmers' Journal." As director of the gardens and exhibitions of the Royal Botanic Society, his good taste, skill, and courtesy were invaluable in making the Regent's Park shows worthy of their great popularity, both with the public and exhibitors. MR. MARNOCK was the first to arrange a flower show in a picturesque manner, and well he succeeded. Indeed, notwithstanding the many and meritorious attempts in the same direction that have since been made, the arrangements for flower shows in the Regent's Park are still admitted to be the best. On his retirement from the curatorship of the Royal Botanic Gardens, the exhibitors presented him with a handsome testimonial, as an expression of their esteem for the way he had managed the exhibitions of the society. For genuine kindness and courtesy to those brought in connection with him, MR. MARNOCK has, through a long and honourable life, stood pre-eminent; and it is not too much to say, that few men have secured so many friends and made so few enemies. With respect to his more recent works, some of which are enumerated above, our own opinion is that as regards design, and taking all the circumstances and capacities of each place into consideration, they are the most beautiful, and in all ways satisfactory, we have seen in any country.

THE GARDEN.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

LEICESTER SQUARE AS A GARDEN.

The public, through the daily and weekly journals, know all about the recent history of Leicester Square; it falls to us to discuss, from a purely professional stand-point, the garden into which the square has been converted. A garden of any kind, in lieu of the nuisance of Leicester Square, with its fragments of the leaden horseman, its dead dogs and cats, and its decaying and not inodorous rubbish of various kinds, is a precious boon to the district, and the most notorious eyesore in London is seen no more. But we have scores of squares needing like changes; and the manner in which this transformation has been done, being likely to influence future work in the same direction, it is desirable that the points in which the design of Leicester Square is glaringly deficient should be fully made known to all interested in such improvements. The first and chief defect in the new garden is that it is too much "cut up." There is a broad walk immediately circling the fountain, and another walk all round, between that and the enclosure, and then there are likewise four other walks, one from each of the four entrances, intersecting the external walk, and leading directly to the one round the fountain. This needless prevalence of gravel, instead of turf, is a radical mistake; it is a repetition of the tones of the surrounding houses; it wears the eye, and destroys all repose. It is a similar mistake to that committed in planning the garden of the Royal Horticultural Society at South Kensington, in which case the elaborate pseudo-gravellings were varied in tone by the adoption of different coloured brick-dust for different walks, with the view, perhaps, of not being too dependent for colour upon the gardener and florist. But the effect is cold, hard, and uninteresting; there is, also, in that example of London gardening a super-abundance of statuary, and an overdone and glaring fountain, far too big for the area in which it is placed, which we notice here, because there are very similar defects glaringly noticeable in the laying out of the new Leicester Square garden. The fountain, for instance, like that of the Horticultural gardens, is too big for the space, while the lesser pieces of sculpture dotted about would be better away. The walks, as before observed, are too many; and the area for the refreshing green of turf is thus made too small. In short, there is far too much of the architect and sculptor, and too little of the gardener. This is a great, but, very common, defect in the creation and embellishment of town gardens. The planning of the turf and walks, and the selection of trees, and the forms and situations of the plantations, should be under the exclusive management of an eminent gardener. The gardener, on the other hand, must not attempt to design the fountains or statues, just as the architect or sculptor must not meddle with the special work of the gardener. We have, in the overdone architectural gardening at the head of the Serpentine, a hideous example of the results of a contrary system to the one advocated. But, to return to Leicester Square, let us see what could be done to relieve the eye from that intolerable deal of gravel walks. Either the one round the fountain, or the external one might be altogether suppressed. The centre should have been an open expanse of verdant turf, and the only walk required, was a sufficiently wide one around the Square, with the needed number of short walks leading from the entrance to this. In the centre where there ought to be repose, there is nothing but stone, chairs, and gravel—and confusion. As for the planting, much is wrong—both as to the kind of trees selected, and the manner of their disposal as to position. It is very curious that in spite of all the experience of the constant failure of evergreens in the London squares, that no kinds of single deciduous trees (or scarcely any) have been employed in the planting of Leicester Square; Rhododendrons and Portugal Laurels are the plants chiefly made use of, though a moment's thought, with all the experience that our town

plantations furnish, would have shown that trees which do not shed their leaves annually become so encrusted in soot after a single winter in the midst of London smoke, that they dwindle into miserable and stunted objects, anything but ornamental; and, indeed, wretched to look upon. Deciduous trees, on the other hand, which are provided by Nature with a new suit of greenery every spring, suffer comparatively little injury from the smoke-plague of our myriad chimneys. In Lincoln's Inn Fields, Brunswick Square, Russell Square, and other spacious enclosures, the deciduous trees, from Lilies up to Limes and Planes, present, on the contrary, as fine an appearance as they do in the purest country air. The expensive standard Portugal Laurels, and fine Rhododendrons now planted in Leicester Square, may simply be looked upon as planted there to die, within a couple of years certainly, and to become wretched objects after the effects of a single winter's smoke work. It would seem, in matters horticultural, either nobody observes what goes on in London or nobody takes a lesson from what occurs. What has become of all the very expensive Portugal Laurels and other fine evergreens planted in the Horticultural Gardens at South Kensington? Let anyone go into Hyde Park now and see the scare-crow Cypress along Park Lane, and the miserable Conifers near the Corner, and judge how unwise it is to plant many evergreens even in our parks. But we are rich and foolish enough to go on buying and planting costly evergreens, and carting them off, when nearly dead, to the rubbish-heap, replacing them again with costly nursery specimens. One thing is certain—that the only way of preserving in good health the shrubs planted in Leicester Square will be to transport them bodily to some pleasant country every autumn, bringing them back in early summer. As regards the central fountain and statue, it is a fairly-designed, well-executed, piece of work, when judged by itself; but it occupies far too much space in a small enclosure like that of Leicester Square. The diameter of its inner circle, without the external one, with its complications of bracket work and vases, would have been in better proportion with the area in which it is placed. Again, the marble fosse or fosses occupying the space between the inner and outer circuit of the design are fitted for the reception of water and not for the display of flowers, with which they are now filled. There is also an extraneous feature in the fountain work, in the shape of a metal guard or gallery, the effect of which is puerile and incongruous, and should be removed. The effect of the metal railwork of the enclosure is, on the other hand, good and appropriate; and the novel feature of reducing it to about half the height of the usual enclosures of our squares is a manifest improvement, if our London roughs, who are certainly getting a little smoothed down, can be induced to respect it as a boundary line at a time when the gates are closed. It is only right to add that, though Mr. John Gibson, jun., has carried out the work he is not responsible for the design, which is, we believe, wholly that of the architect. Hence, of course, the reason why gravel and stone usurp the place of Grass and flowers. Let us hope that the absence of the only vegetation that can thrive in Leicester Square is not intentional, and that it will be remedied in autumn. Should this be so, we trust those trees which, like the Lime, become rusty and lose their leaves early in summer, may be avoided, and such as the good kinds of Robinia, which preserve the freshest verdure till late in the autumn, not forgotten. A square, with a few dying evergreens in winter, and without any more stately vegetation, would prove a sorry prospect at any season. Trees that will bear the London climate and smoke, and which attain to a considerable size when full grown, would eventually become a fine feature in Leicester Square; to have the surrounding houses partially concealed by their uppermost branches, and to walk among their shadows in the warm days of an English summer, might become a pleasure to many generations of Londoners. It should not be forgotten that the many seats provided will be useless, and the gardens not frequented in hot weather, if there be no trees to give shade. The opening day (Thursday) was of the kind that makes even a garden, without shade, far from agreeable. It is hoped that this bold innovation will lead to many of the dismal squares of London being opened and improved.

NOTES OF THE WEEK.

— THE following Lilies are now in bloom at the gardens, Weybridge Heath, viz.:—*Lilium auratum*, *L. Brownii*, *L. canadense flavum*, *L. c. rubro flavum*, *L. c. rubrum*, *L. californicum*, *L. columbianum* (just over), *L. coridion*, *L. croceum*, *L. giganteum*, *L. Humboldtii*, *L. Kramerii* (very large mauve-purple flower), *L. longiflorum*, *L. parthenocion*, *L. parviflorum*, *L. philadelphicum*, *L. puberulum*, *L. Thunbergianum atrosanguineum grandiflorum* (very fine dark colour), *L. T. bicolor*, *L. T. aureum*, *L. T. marmoratum*, *L. T. maculatum*, *L. Washingtonianum*, white flowered; also a variety of it sold by Messrs. Backhouse—this has almost white flowers which changed to purple, a handsome flower—*L. W. purpureum*. The following so-called varieties of *L. umbellatum* were bought under the following names; but, although they were all in bloom side by side, neither Mr. Wilson nor his gardener could recognise wherein their differences consisted; they are fine showy flowers, viz.:—*L. u. grandiflorum*, *L. u. erectum*, *L. u. maculatum*, *L. u. Sappho*, *L. u. fulgidum*, *L. u. incomparable*, and *L. u. punctatum*.

— MR. STAPLETON, of Spring Grove House, Isleworth, writes to us as follows:—"The thunder-storm, which passed over this neighbourhood on the 24th ult., will be long remembered on account of the tremendous fall of hail with which it was accompanied. In a few minutes the ground was thickly covered, so that it presented quite a wintry appearance. The hailstones being unusually large, much damage was done to the fruit crops and bedding plants. Strawberries were deeply indented by the hailstones, which has caused them to rot upon the ground; Pears on espaliers were also much damaged, the fruit, wherever exposed, being marked as if by shot. In the flower garden Coleuses are literally stripped of their foliage, and Geraniums completely riddled; Elm and Chestnut trees also suffered severely. The storm does not seem to have extended far, as but a short distance from Spring Grove nothing was known of it."

— A MAGNIFICENT specimen of *Odontoglossum vexillarium* is now in flower in Mr. Rucker's well-known collection of Orchids at Wandsworth. The plant in question has one young pseudo-bulb, which has produced four flower-spikes, bearing in all fifteen flowers of remarkable size and substance. This variety has blossoms of a soft rosy hue, and is one of the finest *Odontoglossum* we have yet seen, the individual blooms and the entire plant being far finer than the specimen portrayed so faithfully by Fitch in the current number of Bateman's beautiful "Monograph" of the genus *Odontoglossum*. Another plant bears thirteen deeper-tinted flowers, rather smaller in size than those to which allusion has just been made, but still extremely effective. These plants more than confirm the excellent opinion formed of this *Odontoglossum* by its fortunate introducers, Messrs. Veitch, who, it will be remembered, exhibited a specimen of it last year at South Kensington with twelve flowers on two fine spikes. It appears to possess the singular habit of producing a spike from the axil of each sheathing leaf; while, in exceptionally robust and well-grown plants like Mr. Rucker's, a spike is often produced from the apex of the last-formed pseudo bulb. Even *O. Alexandrae*, charming as it undoubtedly is, is inferior in beauty to this fine kind, which, when it becomes thoroughly established, will be found to be one of the most beautiful and effective of all Orchidaceous plants.

— AN interesting communication was made by Mr Darwin to the Scientific Committee of the Royal Horticultural Society at their meeting on the 1st inst., relating to some observations he had recently been making on *Pinguicula*. The reader will remember that he has already published some remarkable facts regarding the seizure of flies by *Dionaea* (Venus's Fly-trap) and *Drosera* (Sundew), which lead to the conclusion that the insects entrapped are made use of for the alimentation of the plant. After the fly has been seized by the leaf, an acid secretion distils from the latter which enables it to digest the nitrogenous matter in the insect, which is absorbed into the plant, and the rest rejected. Mr Darwin has been regarding the genus *Pinguicula* from the same standpoint. Its leaf, indeed, has no hairs by which either to entangle or retain flies or other insects; but it is covered with an adhesive secretion, which, if it does not at once glue any insect that alights on it to the spot, at least prevents its escape as effectively. The leaf is reflexed at the margins, so as to become a kind of tray, over whose edge the entangled sticky insect must find it difficult to clamber. Further he finds that the *Pinguicula* digests albuminous subjects placed or alighting on its leaf, in the same way as the Sundew or *Dionaea*. If an insect or piece of meat, or a Cabbage seed (a seed rich in albumen), or, it would almost appear, any other organic substance is placed on the leaf, it, like the Sundew, throws out a secretion, which, as in it, is acid, and which acts as a solvent to the albuminous matter exposed to it. Moreover, the leaf becomes slowly reflexed over it, and distils this secretion above the object as well as below it. After twenty-four hours it reverts to its natural position and the secretion is re-

absorbed. Mr. Darwin infers that the purpose of this is to feed the plant. We shall await the publication of his paper with impatience, and until we have had the opportunity of reading it deliberately and digesting it at leisure, we shall reserve our judgment upon it.

— THE Place du Trône, in Paris, is about to be converted into a public garden, with the usual accompaniments of Grass, flowers, shrubs, trees, and fountains.

— MESSRS. HOOPER, of Covent Garden, have sent us a small spike of *Lilium Washingtonianum* in flower. They state that when the blooms first open they are quite white, and that they afterwards change to lilac, the two colours on the different spikes having a beautiful effect. It is, without doubt, a chaste and charming Lily.

— SOME of our contemporaries are enthusiastic about having found the *Genista virgata*, of Madeira, a handsome shrub, in flower in Mr. Waterer's nursery. It is, however, not so rare as one would suppose from this discovery; a large shrub of it has for many years adorned the long mixed border in Kensington Gardens.

— THE flowers of the White Lily (*Lilium candidum*) having expanded in Paris from the 13th to the 17th of June, the harvest in the basin of Paris ought to commence about the 20th of July. This observation is founded upon a relation that appears to exist between the flowering of this plant and the ripening of cereals. So many days (it is said) as the flowering of the White Lily precedes the festival of St. John, just so many days before the 1st of August will the cutting of cereals commence. During all the years that we have made this remark, says Mr. Carrière in the *Revue Horticole*, facts have confirmed it.

— THE different varieties of the beautiful *Iris Kämpferi*, are generally considered somewhat difficult to manage; but in the Wellington Road Nurseries there are now numerous beautiful and distinct forms of this *Iris*, varying from pure white to the richest violet-purple, all in full flower, planted out in the open ground. Although perfectly hardy, it increases but slowly, and is on that account rarely seen outside the few trade collections in which it is grown. Messrs. Henderson's plants are growing in ordinary garden soil, but it is thought they would do even better in a moist situation. One fine variety of *I. Kämpferi* exhibited by Messrs. Henderson the other day at South Kensington, bore some resemblance to a large purple *Clematis*; its six petals were perfect, i.e., they were all of equal size, instead of having three partially suppressed, as is generally the case in the group to which this *Iris* belongs. It was stated at the meeting in question, that the deviation from the normal type just alluded to, distinguished this *Iris* from *I. laevigata*, which it otherwise closely resembles.

— AT a meeting of the Court of Common Council, held the other day to further consider the advisability of rebuilding Farringdon Market, after considerable discussion, the following amendment was made by Mr. Isaacs:—"That whereas the site of the present Farringdon Market is of considerably greater value than that adjoining the Metropolitan Meat Market Extension; and that whereas the latter site has the advantage of frontages in four streets, and of contiguity to three principal lines of railway, which would enable growers living at a great distance from the metropolis to supply the London markets with fresh vegetables at prices considerably below the current values; and that, whereas a market could be erected on the new site without displacing the trade at present carried on in Farringdon, this court is of opinion that a new fruit and vegetable market should be erected on the site adjoining the Metropolitan Meat Market." Upon a division, this was carried by 55 to 33 votes. The Markets Committee were then instructed to obtain plans and estimates for a new fruit and vegetable market on the site adjoining the Metropolitan Meat Market, and to report to the court.

— A NOBLE plant of *Cordyline australis* (Hooker)—*Dracena australis* (Forst. Prodr.)—is now finely in flower in the Botanic Garden, Glasnevin. It is a New Zealand plant, and not the Norfolk Island plant, which goes under the name of *Cordyline australis* in our gardens. The latter is *C. Baueri* (Hooker)—*Charlwoodia australis* (Sweet), and *Dracena australis* ("Bot. Mag.")—which, though often seen in our large conservatories, is not a hardy plant in any part of the British Isles. The plant at Glasnevin, as we learn from Dr. Moore, has stood without any protection during the last seven years, and has now a stout straight stem a foot in circumference, and nearly 14 feet high. The panicle of inflorescence is nearly 2 feet wide at the base, and rather more than 2 feet from base to apex. This fine *Cordyline* was received at Glasnevin, from the Oxford Botanic Garden, thirty years ago, when it was a very small plant; it got too large for the plant houses and was, consequently, put out-of-doors, where it has succeeded admirably. *Chamærops Fortunei* (Chinensis) is also flowering freely out-of-doors at Glasnevin this year; it has been planted out seven years.

THE FLOWER GARDEN.

ORNAMENTAL GOURDS.

THE genus *Cucumis*, familiar to all of us in the form of Cucumbers and Melons, is far more widely known as the source from which we derive these much esteemed esculents than as affording subjects which might be applied to purposes of an ornamental character. It contains, however, many species which possess such a unique and *bizarre* aspect, that they claim a large amount of attention from those who seek after that variety of form and expression, which, irrespective of any pretensions to intrinsic beauty, contributes to lend—if only from mere contrast—an additional effect to many well-studied combinations of fine-flowered or fine-foliaged plants. The cultivation of the Gourd family in our flower-gardens has hitherto been strangely neglected, and our object now is, by a description of a few of the most remarkable species, to direct more general attention to it. On the Continent, Gourds have been long esteemed, either for their singularity or the handsome colouring of their fruits. Being climbing plants, they are employed for covering arbours, trellises, &c., and, although most of them are annuals, the peculiar effect which they produce, will repay the small trouble of an annual sowing. The subject of our illustration, the Gooseberry Gourd (*C. grossularioides*) is one of the handsomest of the family. It forms creeping stems about 8 feet long, and of the thickness of a goose-quill. The fruit, which are produced in great abundance, are as large as a good-sized Gooseberry, and are finely marked with alternate longitudinal bands, of very dark and very light green. They are so bitter in taste as to be inedible, and so numerous that a single plant will often bear from 500 to 800 fruit. Although the plant is a native of North Africa and Arabia, it can be advantageously grown in the open air in this country during the summer, and may either be sown, in the place where it is intended to remain, about the middle of May, or, in a hot-bed under a frame, in March or April, and afterwards transplanted, with a good ball, into a bed of spent hot-bed material, or into a hole filled with stable-manure, covered with some inches of soil. Although not absolutely necessary, frequent waterings during the heats of summer will be found useful in encouraging a vigorous growth. Another very singular species is *C. metuliferous*, which grows about 4 or 5 feet high, and bears large egg-shaped irregularly-nibbed fruit, 4 to 6 inches long, studded with huge prominent spikes, and of a fine scarlet colour when ripe. It is supposed to have been first discovered by Dr. Livingstone in Southern Africa, in the Caffrarian district.

The variety called Teasel Gourd (*C. dipsaceus*), a native of Central and Eastern Africa, grows about 7 feet high, with very slender stems, about as thick as a goose-quill. The fruit is about 3 inches long, of a regular oval shape, yellow when ripe, and densely covered with long stiff hairs, so that it very much resembles the flower-head of the Teasel before the flowers have expanded. It presents a marked contrast to the fruit of many of the other species. In culture, it requires to be treated in the same manner as the Gooseberry Gourd. A perennial species from Nubia and Abyssinia (*C. Figarei*), found on the mountains of those countries at 6,500 feet

altitude, very much resembles the Gooseberry Gourd in the appearance of its fruit, which, however, is somewhat larger, and destitute of the long spines which are exhibited by the former. It merely bears a few very short scattered points, which are chiefly collected around the base. Five varieties of this species have been noted. In Abyssinia, the roots of this plant, which possess a very bitter property, are said to be employed as a remedy in cases of madness. Enough, perhaps, has been stated to show the wonderful variety which exists amongst the fruits of this family of plants, and we shall conclude with the following enumeration of some species now in cultivation, which present a most extraordinary diversity in the shape and colouring of their fruit, and seeds of which are easily procurable through any of our leading nurserymen. Among the finest of the larger-fruited sorts are the Turk's Cap varieties, such as Grand Mogul, Pasha of Egypt, Viceroy, Empress, Bishop's Hat, &c., the Serpent Gourd, Gorilla, St. Aignan, Mons. Fould, Siphon, Half-moon, Giant's Punch-bowl, and the Mammoth, which weighs from 170 pounds to upwards of 200 pounds; while, among the miniature varieties, the Fig, Cricket-ball, Thumb, Cherry,

Striped Custard, Hen's-egg, Pear, Bottle, Orange, Plover's-egg, &c., are most interesting kinds, and particularly useful for filling vases, &c. All these, as well as many others, grow well in our climate in summer, and do not require the protection of glass or any other shelter. The directions given for the culture of the Gooseberry Gourd will be found applicable to all the rest; those that are sown in frames early in the season being gradually hardened off by a judicious admission of air before they are finally planted out. This course, however, need only be pursued when an early growth is desired. The plants, as a rule, are tenacious of life, and will exist with a scanty supply of water and in indifferent soil; but, if it is desired to grow them to their highest degree of perfection, they will, like their congeners the Melons and the Cucumbers, be found not insensible to the advantages of a rich and mellow compost, and a liberal allowance of water at all times. These conditions are,

in fact, essential to the abundant production of well-developed, finely-shaped, and richly-coloured fruit.

W. M.

The Gooseberry Gourd.

SAXIFRAGES.

By J. C. NIVEN, Botanic Gardens, Hull.

The None-so-pretty Group (Continued from p. 477).

S. Geum of Linnaeus—though amply distinct from the preceding species, *S. umbrosa*, when seen in its true typical character, possesses also many variations that, in my opinion, may be traced to a strong tendency to hybridisation between the two species, there appears to be a sort of collateral cousinship amongst them, whose limit is so extensive as to form a perfect puzzle to the descriptive botanist. The true specific type under consideration has round reniformly cordate hairy leaves, crenate or dentate as to the margin, and showing but a small trace of the hard cartilaginous edge that we had in the preceding species; the foot-stalks of the leaf are hairy, rounded below, channelled above, and longer than those of *umbrosa*. The whole plant in aspect bears so close a general resemblance to the old London Pride—more especially in the flowers—that they may readily be mistaken by the ordinary observer for the same

plant. Our present species is not, however, possessed of such a vigorous constitution, nor is it able to stand the extremes of cultural neglect, under which, as I before observed, the other appears to flourish. Like *S. umbrosa*, it seems to have no recorded habitats beyond Britain, the Pyrenees, and the central mountains of Spain, but I am strongly of opinion that the remarks I made on the geographical distribution of that species are equally applicable to this.

S. Geum var. *polita* of Haworth is of much smaller and denser growth, devoid of hairs both above and below the leaf, cordate at the base, but not reniform the marginal notches, broad and blunt pointed.

S. Geum var. *dentata* of Link, as its name implies, is specially distinguished by the small sharp serratures, by the foot-stalk being flattened at the top, not channelled, and by the slightest tendency in the orbicular leaf to run down the margin of the petiole; the flowers, besides the usual crimson spots, have a single yellow blotch about the centre of each petal, which enhances their beauty much on a close examination, though hardly noticeable at a distance.

S. Geum var. *elegans* of Mackay has its leaves slightly more oval than orbiculate; its chief characteristic, and on that account the name *elegans* was given by the worthy old Saxifragean Doctor, results from the flowers being densely dotted over with both yellow and crimson spots. It grows abundantly in one or two localities in the south and west of Ireland, but we have no record of this variation occurring on the Continent.

S. Geum var. *hirsuta*.—Considered as a distinct species by Linnaeus, and merged into the variety *dentata* by Engler, possesses many features especially its own, sufficient, if not to raise it absolutely to a specific title, at least, to constitute it a well marked variation. It has the true characteristics of our typical species, both in form of leaf and foot-stalks, its leaves are more upright, margined with very blunt crenatures, and covered both above and below with long erect hairs; as to colour, the whole plant is of a much darker green than any of the preceding; and the flowers almost devoid of the crimson dots. This plant, when growing with the vigour as it does in the southern Irish mountains, is supposed, by some, to be allied to *S. repanda*, if not identical with it; but, independent of other botanical points, the thick fleshy leaves of the latter, as compared with the former, renders it readily distinguishable.

S. cochleariæfolia of Schrader is identical, from Engler's description, with a species long in cultivation under, I feel bound to say, a much happier title—namely, *S. cochleata*—than that which Schrader has given; but, for it I can find no authority beyond that of gardens; and, as the other has a true descriptive status, I suppose we must yield here to precedence. Be the name as it may, this is a singular little plant, and perfectly distinct. It forms dense compact tufts of glabrous, rounded, cordate leaves, oblique at the base, hard and horny in substance, and markedly concave; the margins, indented irregularly, are cartilaginous; the flower-stems are about 6 inches high, covered with minute glands, and distinguished by the presence of two or three wedge-shaped leaves. Our plant, as regards foliage, does not exceed 2 inches in height, and always presents a dark bronzy-green appearance, its concave or, as I would term them, cochleate leaves, intermingling with the adjacent and opposite leaves, destroys altogether anything in the form of a rosette-like arrangement. What, then, is its history? Referring to Engler, we find it occurring in his hybrid addenda to the *Robertsonia* section, where it is represented as a cross between *Geum* and *rotundifolia*, a parentage that I must candidly admit I entirely fail to recognise on either one side or the other, whether as regards foliage or flowers; which latter, by the way, are very rarely produced. He further states that it is a hybrid found by Villars in his garden as long ago as the year 1793, and having since occurred in the Berlin Botanic Garden. Be this as it may, it has all the distinctive characters of a true species; and, as such, I am disposed to recognise it, and should like to see it retained under its garden title of *S. cochleata*, at least, until some more likely ancestry for it is pointed out.

S. cuneifolia of Linnaeus, is sometimes met with under the name of *S. cuneata*, but the latter is given by Willdenow to a plant belonging to the Mossy section; hence, however unfortunately similar the nomenclature may be, the two species are perfectly distinct. The leaves in this plant are glabrous, ovate, with the blade rounded at the apex and gradually narrowing into the petiole in a wedge-like fashion for at least half its length. The margins are distinctly cartilaginous, very slightly notched, collectively the leaves form a tolerably dense arrangement of moderately-sized rosettes, from the centre of each of which rises a panicle of flowers, some 6 or 7 inches high, more slender, and the individual flowers much smaller than in *Geum*. It is a native of nearly all the mountain ranges in Southern Europe.

S. cuneifolia var. *daurica* of Schlicher, although regarded as synonymous with the foregoing, is, I think, fully entitled to rank as

a distinct variety, arising from the following peculiarities. Its leaves are more acutely pointed, the apex being distinctly reflexed, and the margins more irregularly notched; added to these, the arrangements of the rosettes is far from being so uniform. Some rise above the general surface, giving a much laxer character to the growth of the variety than is the case in the original species.

S. cuneifolia var. *infundibulum*.—Of this name no mention whatever is made by Engler, and yet it is an exceedingly distinct variety. The funnel-shaped Saxifrage has its leaves almost entire in the margins, round at the points, and incurved in such a manner that each rosette forms a perfectly natural foliated cup, from the centre of which rises the panicle of flowers about 1 or 5 inches high; indeed, I know of nothing more striking than the effect produced in a well-grown plant of this variety, each rosette being a facsimile of its neighbour. In cultivation the most appropriate position in a rockery for both this and the former varieties is when growing in a decayed old stump of a tree, thus raising it above the general ground level, and giving it an opportunity to overhang the edge, which it will soon do, with a degree of grace and elegance that few plants can surpass. I originally obtained it from the Copenhagen Botanic Garden, and, though not absolutely certain, I think it is one of Dr. Lange's very appropriate names.

S. cuneifolia var. *multicaulis* of Lange.—This, like the former, is tabulated as a synonyme, but is equally entitled with it to be considered as a variation, if not indeed a true species. Its leaves are slender, much narrower than the foregoing, and it branches off into numerous trailing stems, not distinct rosettes; it is but a shy grower. I had it in cultivation for about three years from seed, and, just as it was going to bloom, it succumbed to an attack of that pest of all pests—the white grub of the *Otiorynchus*; should any of my readers possess this variety I should be only too glad to add it once again to our collection.

S. capillipes of Reichenbach has been cultivated for years as *S. capillaris*; it is considered by Engler as a variety of *cuneifolia*, to which he gives the name *subintegra*, but I prefer the specific name, to which I think it is fully entitled. It is a perfectly glabrous plant, with rounded leaves, narrowing very slightly into the petiole, entire as to their margins, and of a thick leathery consistency; they are grouped together in wide expanding rosettes, each rosette being supported on a slender woody stem devoid of leaves, hence originates the very appropriate specific name. The flowers are produced somewhat sparsely, and are, individually, much larger than in any of the heretofore named varieties of *cuneifolia*. It is a native of the Apennines, the Alps, and the Tyrol. It is a free-growing species, flourishes well in common garden soil, and, being of a pretty lively green, has a pleasing and effective appearance as a border or rock plant, independent altogether of the bloom.

S. Bucklandi of gardens.—As long as I can remember, this species has been in cultivation in our English gardens, and I have no doubt those who grow it will admit that it ought to rank as a good distinct species; and yet, not only is the name altogether absent in Engler's "Monograph," but there is no species described therein, that, so far as I can make out, can be applicable to our present plant. *S. Bucklandi* is a dense-growing caespitose plant, composed of numerous small rosettes, whose erect foliage and compact arrangement cause the little rosettes to merge into one another, in such a way that they almost lose their individuality. The leaves are small and ovate, gradually narrowing down into a long slightly-ciliated petiole; the upper surface of each leaf is distinctly convex, and the margins almost entire. The tiny panicles of bloom rise to a height of about 3 inches, and produced, as they are in quantities, have a very pretty appearance, adding elegance to the somewhat stiff contour of the tufted little plant.

SNAPDRAGONS.

THESE may be had in flower all through the summer and autumn months, and among the blossoms are forms and markings of the most varied and beautiful kind. Snapdragons are best when treated as hardy biennials. A pinch of good seed sown in a box or pan in a house or frame during the month of March will furnish abundance of plants for any ordinary garden; and when these seedlings are 3 or 4 inches in height they may be placed in the box or pan in which they are growing in the open air until the stems have become hard and wiry; then transplant them into whatever position they are to occupy; and by midsummer, or soon after, they will begin to bloom, and will continue to do so until the end of November. As a rule I find that no other hardy border plant flowers more continuously or more freely than the Snapdragon, and those side shoots that come so abundantly after

the centre spike has done blooming offer most useful material for cut bloom at a time when flowers are of great value. If seed be sown as soon as the earliest pods are ripe, which will be about the end of June on old plants, a batch of seedlings should be raised from it sufficiently strong to stand the winter, and these will flower early in the ensuing summer. The best plants and the finest spikes are produced from those plants that have bloomed the previous autumn, as, if the tops have been partially cut down during the winter, an abundance of strong, robust growth will come up early in the spring from the base of the plant, and these shoots will furnish splendid spikes of flower, varying from 6 to 9 inches in length, all open at once. These would be at their best probably about the middle of June; but if a goodly number of plants be grown there would be little difficulty in getting good spikes for exhibition all through the month. The Snapdragon is a very easily cultivated plant, and, if horticultural societies could be generally induced to encourage its culture by offering good prizes for the best eight or twelve spikes, it would doubtless receive more general attention than it does at present. The most pleasing forms of the Snapdragon are those with flaked and striped flowers, and these come very constant from seed. It is peculiarly noticeable that seedling plants of this striped strain have stripes or flakes on the under sides of the leaves, and the stems are also sometimes marked in the same way. The flower markings are so diversified, that out of a batch of 100 plants scarcely two have flowers exactly alike. Many of them are also bizarre in character, having a coloured ground, and two other diverse colours flaked upon it. In securing a collection for any purpose, it would, however, be unwise to overlook the beauty of some of the self-coloured flowers, or those that have white throats with rich coloured mouths, and especially those that have deep coloured mouths and orange or white lips. Most of these colours are found best in the tall-growing strain; and, as these, when in the second year of growth, will rise to a height of 30 inches, they should be planted several feet from the front of the border, in order that dwarf plants be not obscured. There is a dwarf or Tom Thumb strain that is perhaps best adapted for pot culture. These will grow to heights varying from 10 to 15 inches when in flower, and, in addition to a very free blooming habit, have colours that do not exist amongst the tall kinds. This dwarf strain is just as hardy as the other, and requires the same process of cultivation; but, if planted in the open border, it should be kept in the front row with other medium-sized plants. If seed of these be sown in the spring under glass, plants will be produced that will flower during August and September; and if potted up into 32-sized pots will make a rare display in windows at that time. There are a few very fine double forms of Snapdragon, but these do not seed, and have to be propagated by cuttings. The flowers are very large and massive, and have a curious appearance, but are not, on the whole, so pretty as the single kinds. It is always easy for the grower to perpetuate any favourite kind by means of cuttings, which should be taken from strong side shoots in the summer, and struck under a hand-light in some shady or cool situation.

A. D.

WELSH WILD FLOWERS.

It was after seeing the wild Columbine in a meadow close to the steep rock, known as the "Little Orme's Head," near Llandudno, that I came to the conclusion that old Walton's Culver Keys, the flower about which so many different opinions have been expressed, must have been the *Aquilegia vulgaris*, since it grows wild in sufficient profusion here to enable "garlands" to be formed of it "along with Cowslips." Those who assert, in confirmation of their opinion, that the wild Columbine could not have been the plant alluded to by the old angler, because it is never seen in sufficient quantities to form a garland, should go to Llandudno, and interview it there when in full bloom. The Vernal Sandwort I, likewise, found there, its pearly-white flowers showing out well amid the bare herbage on the mountain's side, and the *Herbe aux Charpentiers* of the French, the *Herb of Taliesin*, as it is called in North Wales, being named after that ancient bard, thrives better there than in any other place in which I have ever met with it, Bangor included, and yet I gathered some fine specimens of it near the latter town, two summers ago, but those taken from the Little Orme were the best. "Pegyl," as the

Welsh women call the Hound's-tongue, is very abundant in the hedges; its lurid look betrays at once its poisonous character; nevertheless, it is, in my opinion, an interesting plant, and its prickly nuts, and smooth seeds, are very pretty objects when viewed through a common microscope. The little Orme cannot boast like the large rock, the Great Orme, of rare shrubs, such as the *Cotoneaster*, which guide books tell one used to be considered a foreign plant, until found there. I see no reason, however, why it should not still be thought so, though very hardy; for, anyone acquainted with that coast must be aware that, in former years wrecks off the Great Orme's Head were unfortunately not unfrequent; what more likely, then, than that the seed collection of some homeward-bound botanist may have been cast on shore to take root among the crevices of that dangerous rock? The botanist, who stays at Llandudno should visit Sychant Pass, a spot rich in rare wild plants, where, among the old Druidical remains he will find much to delight him. *Maen y Campan* (the stone of games), the place where *Eisteddfodai* were held, the *Cromlechs* and the *Carneds* are all covered with different kinds of flowers, and even the old walls of *Braich y Ddinas*, the strongest fortress the Britons ever held in the Snowdon range, are decked with graceful Ferns, Ivy, and yellow Wallflower, whilst the lovely little Maiden Pink (*Dianthus deltoides*) covers the ground with its bright tufts of bloom, but the raven and the chough now reign where the old Welsh Princes waged war against their Saxon foes, and oft-times against each other. The Great Hall, at Conway Castle, where Edward and his nobles held high revel, is given over to the froids of the Hart's-tongue and memories of the mighty dead. The name of *Llewelyn y Llwy Olaf* has almost faded from the land he reigned over, but the descendants of the birds he loved so well to sport with, the royal peregrine and the falcon, may still be seen hovering over the mountain passes, or wending their flight across to the Orme's Head.

Berry Grove, Liss.

H. E. W.

GRAPE HYACINTHS.

(MUSCARI.)

The increasing interest taken in all classes of hardy spring-flowering plants will, probably, make a complete account of this pretty family acceptable to cultivators of these subjects.

Muscari moschatum.—This, the musk-scented Grape Hyacinth, is more remarkable for the fragrant odour than for the colour of its flowers, which are of a dull greenish-yellow tint, slightly shaded with violet, and are produced, in rather dense racemes, 2 or 3 inches long, and containing from twenty to fifty flowers on flower-stalks 4 to 8 inches high, appearing in spring and early summer. The individual flowers are about a quarter of an inch long, and of a tubular pitcher-shape, with the rounded segments of the mouth reflexed in a starlike fashion; leaves, five or six in number, linear, fleshy, about a foot long, and from half-an-inch to three-quarters broad. Native of Asia Minor and the East. A variety, *M. m. flavum*, has yellowish flowers, with purple teeth or segments, disposed in a more oblong raceme.

M. comosum.—Flower-stem, a foot or more high, marked with tawny spots; flowers, of an olive-tinged amethyst blue, or bluish-violet, arranged in a large loose raceme, 6 to 12 inches long, and containing from forty to a hundred flowers, each flower is divided into slender twisted segments, which give it a fringed appearance, most remarkable in the varieties, *M. c. monstrosus* and *M. c. plumosum*; leaves, linear, ribbon-like, channelled, toothed at the edges. Native of Southern Europe and Algeria. A variety, *M. tenuiflorum*, has narrower flowers and leaves. *M. clusianum* is also, probably, a variety with fewer and denser abortive flowers.

M. racemosum.—A well-known kind, very common in old gardens; flower-stem, 4 to 6 inches high; flowers, fragrant, of a deep sky-blue colour, in a dense raceme of twelve to twenty blooms, and about an inch long; leaves, five or six in number, rush-like, speaking 8 to 10 inches long. Native of England and Southern and Central Europe. A variety (*M. pulchellum*), found on Mount Parnassus, has leaves which are less rush-like in appearance, and has larger and more reflexed segments of the flowers. Another, *M. byzantinum*, has a lax few-flowered raceme and erect leaves.

M. botryoides.—A very charming species, with a flower-stem 6 to 9 inches high, and lovely deep sky-blue flowers, with white teeth or segments at the mouth, arranged in a short, dense, and almost globose raceme, 1 to 1½ inches long, and containing from twelve to twenty flowers; leaves, three or four in number, linear, somewhat glaucous, 6 to 12 inches long. Native of Southern Europe. A variety (*M. b. Lelievrii*), found in Western France, has a denser raceme and thicker flowers. It also blooms earlier (about the end of February) in its native habitats.

M. alpinum.—Flower-stem, 1½ to 2 inches high; flowers, sky-blue, in somewhat loose racemes 1 to 1½ inches long, and contain-

ing from twelve to twenty flowers each; leaves, four or five in number, linear, fleshy, 2 or 3 inches long and about a quarter of an inch broad. Native of Asia Minor, in the Alpine districts of Cilicia and Taurus.

M. Cupanianum.—A Sicilian species, with broadly-linear, flaccid, channelled leaves, and flowers disposed in a longish dense raceme.

M. caucasicum.—Flower-stem, 6 to 8 inches high; flowers, of a livid blue, in a loose raceme from 3 to 4 inches long, and containing from twenty to forty blooms; leaves, two to four in number, fleshy, linear, 6 to 9 inches long and about half an inch broad. Native of arid parts of the Georgian Caucasus.

M. Bootanense.—Flower-stems, 5 or 6 inches high; flowers, blue, twelve to twenty in number, borne in a raceme 2 to 2½ inches long and 1 to 1½ inches broad; leaves, five or six in number, fleshy, linear, very convex on the back, 5 or 6 inches long and about a quarter of an inch broad. Native of Bootan.

M. Pinardi.—Flower-stem, 6 to 8 inches high; flowers, in a loose raceme of from fifty to eighty blooms and 1 to 8 inches long; leaves, four to six in number, 6 to 9 inches long, and about a quarter of an inch broad. Native of Asia Minor.

M. longipes.—This species resembles *Hyacinthus ciliatus* in habit, but retains the distinguishing flowers of its genus. They are produced in a pyramidal raceme, the pedicels of the lower flowers being often 2 inches long. Leaves, linear, roughly-toothed, shorter than the flower-stem. Recorded by Boissier as a native of Philistia.

M. Gussonii.—Flower-stem, 3 or 4 inches high; flowers, in a rather loose raceme of twenty to thirty blooms, and from 2 to 2½ inches long; leaves, three or four in number, linear thread-like, and 5 or 6 inches long. Native of Sicily.

M. latifolium.—This species is distinguished by never producing more than a single leaf, which is 9 to 12 inches long and from three-quarters to an inch broad; flower-stem, slender, a foot or more high; flowers, in a moderately dense raceme of twenty to thirty blooms, and from 1½ to 2 inches long. Native of Phrygia in the Pine forests of Mount Monrad-Dagh.

M. Bourgaei.—Flower-stem, 1½ to 2 inches high; flowers, of a deep sky-blue colour, in a short loose raceme of six to ten blooms, and from half to three-quarters of an inch long. Native of Lycia, near the snow-line on Mount Ak-dagh.

M. maritimum.—Flower-stem, 3 to 6 inches high; flowers, in a loose raceme of twelve to twenty blooms, and from 2 to 2½ inches in length; leaves, three or four in number, fleshy, linear, 6 to 9 inches long, and about a quarter of an inch broad. Native of Algeria.

M. neglectum.—Flower-stem, 6 to 9 inches high; flowers, fragrant, of a deep sky-blue colour, with whitish reflexed segments at the mouth, and arranged in a dense raceme, 1½ to 2 inches long, and containing from thirty to forty flowers; leaves, numerous 9 to 12 inches long, linear thread-like, deeply channelled. Native of France, Germany, and Italy. This appears to be little more than a larger-growing variety of the preceding species.

M. commutatum.—Nearly allied to *M. racemosum*; flower-stem, about 6 inches high; flowers, of a deep sky-blue colour, almost scentless, in a dense raceme of twelve to twenty blooms; leaves, five or six in number, fleshy, narrowly linear, channelled, 5 or 6 inches long. Native of Southern Europe, Palestine and Armenia. *Botryanthus albo-virens* of Todaro is probably a white-flowered variety of this species.

M. grandifolium.—Flower-stem, 5 or 6 inches high; flowers, of a livid blue colour, in a dense raceme of fifteen to twenty blooms, and about 1½ inches in long; leaves, five or six in number, 15 to 18 inches long, and about 1½ inches broad. A large-leaved species; grown in the Royal Gardens at Kew. Native country unknown.

M. Aucheri.—Flower-stem, slender, 2 to 4 inches high; flowers, very small (scarcely half an inch long), in a short dense spike of six to ten blooms; leaves, two in number, fleshy, 2 or 3 inches long. Native of Asia Minor.

M. pallens.—Flower-stem, 3 to 5 inches high; flowers, white, oblong, less pitcher-shaped than those of any other species, in a dense raceme of twelve to twenty blooms, and less than an inch long; leaves, numerous, thread-like, 6 to 8 inches long, glaucous, rounded on the back. Native of the Caucasus and Iberia.

M. parviflorum.—Flower-stem, slender, thread-like, flexuose, 4 to 8 inches high; flowers, of a pale sky-blue colour, very small, six to twelve in number, produced in a loose raceme of six to twelve blooms, and from ½ to 1½ inches long; leaves, six to eight in number, linear, thread-like, 4 or 5 inches long. Native of Spain, Sicily, Algeria, Egypt, and Syria.

M. Heldreichii.—Flower-stem, 4 to 6 inches high; flowers, of a fine amethyst-blue colour, somewhat like those of *M. botryoides*, but nearly twice as large, and arranged in a longer spike. Leaves,

five or six in number, rush-like, 8 to 12 inches long. Native of Mount Parnassus, in Greece.

The preceding account, translated from Mr. Baker's Latin descriptions in the *Journal of the Linnean Society*, includes all the known species of *Muscari*, only some of which, however, are in cultivation; several kinds, as may be seen from the descriptions, presenting no features of marked interest. The kinds which are grown are valuable as distinct and pretty plants, flowering in spring and early summer. Their proper position is either in the front row of the choice border or on rock-work, or they may be advantageously grown as window-plants in pots or boxes. In all cases, they thrive best in rich, deep, sandy loam, and are easily multiplied by separation of the bulbs every third or fourth year. W. M.

Deep Planting best for *Primula farinosa*.—This grows in my neighbourhood, and I have for years had specimens of it in my garden. I procured them in April; and, in the following June and the succeeding season, the flowering was usually satisfactory; but, after that, I generally lost them—they did not reappear after the second winter. Attributing the failure to frost forcing the roots out of the ground when deprived of their mossy covering, I adopted the following mode of culture, which has proved successful:—About the middle of August I replanted all, dividing the strongest; and, after stirring the soil and adding a little fresh material, I took each plant, and grasping it around outside the outer leaves, and so enclosing the inner ones, pressed them together and inserted the plant so deep as to leave only the tips of the outer leaves visible above the soil, and finished by pressing the latter firmly and compactly all around. Notwithstanding this deep planting, I have, after a severe frost, occasionally observed protruding roots, and had to apply my foot with some degree of pressure to force them back into their places; nevertheless, the result has proved that such rough treatment did not prevent the plants from doing well. These *Primroses* like a light peaty soil; and, being bog plants, dryness must be avoided when in flower; they require to be watered freely. Thus treated, my plants have increased rapidly and flowered strongly, having stems from 12 to 14 inches high, bearing noble umbels, each consisting of upwards of forty florets. *P. cortusoides* has succeeded equally well under the same treatment, and it is probable that all the *Primulas* of the deciduous section would also succeed.—Ry.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

***Sideritis hyssopifolia*.**—This is a very quaint-looking, and, I believe, rather an uncommon plant of the labiate family. It grows about 9 inches high; has a dense-spreading habit, a profusion of long spikes of pale yellow or sulphur-coloured flowers. Its low prostrate habit renders it admirably adapted for rock-work, especially when the latter is of a dark colour.—T. WILLIAMS.

Peat-loving Plants.—Can any of your correspondents inform me from experience what is the best kind of bed or frame in which to grow the North American Orchids, Bog plants, and such things as *Pyrolas*, *Trilliums*, and other small and delicate plants of like nature? Is it necessary to use peat alone? and is *Sphagnum* a good thing? It seems that most of these plants like to be kept dryish in winter, and very wet in summer, which is exactly the reverse of what our climate naturally is. How can this be managed?—H. E.

British Ferns in London Areas.—A prominent feature of London areas in summer is the abundance of native Ferns which they often contain, and which appear to thrive amid the dust and smoke almost as well as in the country, a circumstance probably owing to their shady cool position, and to the copious supply of water which they get. I know several streets in the heart of London where they grow year after year as fresh as possible in the areas, and the more shady these are, the better the Ferns do. My principal object in writing, is, however, to draw attention to the rocky Fernery that was added to the South Kensington Museum some years ago. This is now very attractive, the Ferns (most of which are common native species) being fresh and vigorous and not a bit less graceful than their tropical or exotic congeners.—F. W. B.

Alpine Veronicas.—Every lover of plants who possesses a garden ought to grow the following Veronicas, viz.:—*V. multifida*, *pectinata*, *repens*, *saxatilis*, *taurica*, and *veronicaea*. They are all perfectly hardy, and require but little attention. *V. repens* is a beautiful plant for the spring garden, and for that purpose cannot be grown too largely. A gentleman passing my garden last spring, when an edging of it was in full bloom, inquired, "what is that plant which is as white as snow?" *V. taurica* is also quite a gem if left undisturbed for a year or two; it is just now blooming beautifully with me. I have also planted a very beautiful variety of *V. saxatilis*, called *Gruveli*, a kind with bright rose-coloured flowers, which I received from Messrs. Backhouse, of York. It is worth inquiring after.—J. WHITEAKER, *Morley, near Leeds*.

Flowers for Dry Barren Borders.—I have a border, in front of my house, in which plants generally refuse to grow, as it becomes very dry and parched during the summer months. What could I obtain to cover it, and bear a few flowers?—W. S. [For a border such as you name, nothing is better than *Antirrhinum*, or "Snapdragons," and *Mignone*. Sow the latter now, and in autumn dig it as deeply as possible, adding a barrow load or two of stable manure, and then sow *Antirrhinum majus* and *Saponaria calabrica* seed thickly all over the surface, and rake them in thoroughly. These are sure to grow and flower well the following summer. A friend of ours lives in a house facing a railway embankment, and, to hide this, he obtained permission to sow flower seeds over it, and just now the *Antirrhinums* are a sight well worth seeing—a perfect mass of brilliant colours.—Ed.]

THE ARBORETUM.

EFFECTS OF GEOLOGICAL POSITION ON CONIFERS.

THE general diffusion of foreign Conifers in this country, and their importance, not only as regards the effect which they will eventually produce in our landscapes, but as regards their intrinsic economic value, induces me to hope that a notice of certain peculiarities, which I have had opportunities of remarking in a few species, may not be unacceptable. In and about Tortworth Park, at the northern extremity of the Bristol Coal Basin, the underlying beds of carboniferous limestone and old red sandstone crop out at a high angle, with occasional beds of the triassic and liassic formations resting on their flanks, producing not only great irregularities of surface, but important differences both in the constitution and quantity of the superincumbent soil. Over the whole of this ground the more common Conifers are planted in great abundance, and, with a few exceptions (owing chiefly, I believe, to geological reasons), they grow rapidly and well. As a general and sufficiently obvious rule, the Conifers thrive in proportion to the depth of the surface-soil on which they stand. This is especially the case with the Deodar and *Pinus insignis*. The rule does not, however, appear to apply invariably to the Douglas Fir (*Abies Douglasii*), as I possess specimens growing as vigorously on the cold and sterile shales of the carboniferous limestone, as others on the deep and warm soil of the old red sandstone. The most fastidious of the Conifers which I have had an opportunity of observing is, undoubtedly, *Cryptomeria japonica*. On the limestone, its leading shoot is always defective, and its growth generally devoted to the formation of a nest-like mass of small shoots; whilst on the old red, a formation deficient in lime, its growth is regular, upright, and graceful, and so rapid, that I have no hesitation in affirming that in this locality it would outgrow the Larch. The Deodar, on the other hand, appears to be the least discriminating, and the most accommodating of all the Conifers. No position, and no variety of soil, appears to come amiss to it; on lime or sandstone, rock or clay, it grows with equal facility—though depth of soil, as before stated, invariably contributes to rapidity of growth. *Pinus insignis* appears to prefer the old red to the limestone; on the latter formation it maintains its health, but its annual growth is comparatively small. The most vigorous specimen of this Pine which I possess stands on a deep loam, formed by the detrital matter of the overhanging hill, at the point of contact of the old red sandstone and the clay of the lower lias. In *Arancaria imbricata*, though planted in considerable abundance, and in every variety of soil, I have not been able to detect any decided preference for one formation over another. It has an evident dislike to a wet locality, and it generally, though not exclusively, thrives best upon a deep soil. *Cupressus funebris* and *Cupressus Goveniana*, are both growing vigorously on limestone rock, with but little surface soil. The former of these trees is thriving equally upon a deep soil of the old red sandstone. *Cupressus macrocarpa* is growing rapidly on the clay of the carboniferous limestone. *Taxodium sempervirens* appears to be extremely capricious in its taste as regards the formation on which it grows; but I have, in several cases, remarked that it thrives and even appears to luxuriate in a shade which proves deleterious, and often fatal, to *Pinus insignis*. There are many other Conifers which appear to manifest habits or tastes peculiar to themselves; but which are either too young, or in numbers insufficient to justify me in attempting to generalise upon them. Indeed, all the remarks which I venture to offer in this short paper are not made with a view to dogmatise upon the subject, but in order to call the attention of persons cultivating this tribe of plants to the importance of selecting the position of such Conifers as show any decided tastes. With some reference to geological position, it is true that many formations are not often met with upon one estate, more especially in one park—the locality in which the more valuable

Conifers are generally planted; but, where such conditions do occur, a knowledge of the formation in which each species appears to thrive best cannot fail to prove important. Before such knowledge can be attained, more extended and more accurate observations will, however, be necessary. [Let us hope that this paper, contributed to the transactions of the Scottish Arboricultural Society, by Lord Duncie, may prove the means of calling general attention to this matter.—Ed.]

ROSY-FLOWERED ELDER.

(*SAMBUCUS ROSEIFLORA*.)

The Rosy-flowered Elder (*Sambucus roseiflora*).

THIS very ornamental variety of the Elder is a seedling from *S. glauca*, to which, however, it does not bear the slightest resemblance. It forms a vigorous-growing shrub, with smooth shoots and branches, and oval-acuminate leaves, green and smooth on the upper surface, and covered with a silvery-white and felted down underneath. The shoots are covered with a green bark, marked with one or two reddish rings at the insertion of each pair of leaves, the rachis of each leaf being generally tinged with violet. The flowers are rose-coloured on the outside of the petals, and white on the inside. They are almost scentless, and are disposed in comparatively short spike-like clusters, broad at the base, and with numerous violet-coloured ramifications. The plant does not run at all at the roots. The parent plant, *S. glauca*, on the contrary, has all its herbaceous parts covered with a dense pubescence, and bears yellow flowers, which have an odour of Citron or Gilly-flower, and are produced continuously, disposed in an umbel. The leaves are different in size and shape from those of *S. roseiflora*, and are pubescent on both sides. The plant also runs very much at the root. Our illustration represents the inflorescence of this remarkable variety, which, in almost every particular, presents a singular contrast and want of resemblance to its parent, and which might, with great advantage, be introduced into our pleasure-grounds among Lilacs, Laburnums, and other flowering shrubs. It is perfectly hardy, different as to soil, but, of

course, will thrive best in a generous loam. In other respects it requires as little attention as the common Elder of our hedges.

W. M.

Extent of Woods in England.—It seems from the official statistics that of the whole surface of England and Wales, less than 4 per cent., or only 1,453,000 acres out of a total of 37,319,000 acres, is occupied by woods, coppices, and plantations. Treating the three ridings of Yorkshire as separate counties, Sussex is the only county which returns more than 100,000 acres of wood, nearly 11 per cent. of its area being thus clothed. The woods of Hampshire are next in magnitude, embracing some 87,000 acres, but forming only 8 per cent. of that county's area. Kent follows with 78,000 acres of woodland, while the adjoining county of Surrey, although returning only some 48,000 acres of wood, shows almost as high a percentage as its neighbour Sussex, since very nearly one-tenth of its whole area is thus employed. These four counties, Hampshire, Kent, Surrey, and Sussex, appear to possess a much larger extent of woodland relatively to their size, than any other area in England.

A good Weeping Poplar.—Poplars of late years are receiving attention, and already our list of weeping varieties numbers four or five distinct kinds. According to our idea of beauty, however, there is but one really first-class tree, and that one is among the finest of all the drooping plants; we allude to the *P. grandidentata pendula*.

For a small-sized specimen, it forms a strong rival to the Kilmarnock Willow, and will, we believe, in time supersede it. There is an objection, however, to its culture, which we must mention: all the Poplar family throw up suckers, more or less; consequently, this trouble will stand in the way of its advancement. Budded upon the Lombardy Poplar, the long, slender branches, reminding one of whips, are full of grace and beauty; and, even when worked 7 or 8 feet high, the branches will extend frequently to the ground in a single season.—*Horticulturist*.

THE GARDEN IN THE HOUSE.

VASE OF SIMPLE FLOWERS.

Just at the present season there are so many flowers in bloom that, when about to decorate a vase, one is puzzled as to what should be selected for that purpose. Being about to redecorate a stand for the centre of a dinner-table a few days ago, I thought I would try what effect I could produce with simple—I might almost say common—flowers. I therefore selected the following, viz., white Water Lilies, wild Convolvulus, Canterbury Bells, Forget-me-nots, and the pink Geranium Christine, together with the addition of a few hardy Ferns and wild Grasses. My stand was a high glass trumpet, which I set in a soup plate, and then filled it with fresh-looking wood Moss, well damped, so as to keep the flowers about to have their stems placed in it fresh. I then commenced to arrange my flowers as follows:—Round the edge I placed some fronds of the Lady Fern (*Adiantum Filix-Femina*) so as to hide the china; I then filled up the interior with four large fully-opened Water Lilies, trusses of pink Geranium between each, and, close to the stem of the trumpet I placed Canterbury Bells, bent a little forward, so as to hang out; the whole being intermixed with fronds of *Asplenium Adiantum-nigrum*, *A. Trichomanes*, and sprays of Oats. In the trumpet I placed, first, a long spray in flower of Convolvulus, which I twined round the stem; this flower is generally considered to be worthless in floral arrangements, because it soon fades, but this is a mistake, for, if placed in water as soon as cut, and not allowed to once flag, it will remain fresh for three or four days. Its young flower-buds will also open equally well as if still growing. After the Convolvulus had been twined to my liking, I then finished off the trumpet with a plume of wild Grasses, through which were interspersed some pink Geraniums, of the same variety as that used in the tazza, and a few sprays of white Forget-me-not. Round the mouth of the trumpet were a few fronds of *Asplenium Trichomanes*, wired so as to droop gracefully over. Grouped round this centre-piece I had eight specimen glasses, four about 8 inches high, and four about 6 inches, placed in such a way that the tallest were towards the top, and bottom, and sides of the table, and the smaller came in corner-ways. The tiny bouquets in the four tallest, matched, as did also those in the smaller glasses. Each little bouquet in the tall glasses consisted of a half-open pink Cabbage Rose-bud, some white Forget-me-nots, blue Lobelia, Hemlock, hardy Fern fronds, and a few spikes of wild Grasses. Those in the smaller glasses consisted of a half-opened bud of the old white Provence Rose, blue Lobelia, Hemlock, and two pips of pink Geranium. When finished, the effect of this group was really very neat and pretty, far more so than I even for a moment expected; and yet, of what was it composed? Of nothing but common flowers, and what may be termed a few weeds. I do not wish it to be inferred, however, that I consider such an arrangement as this superior to one composed of hot-house flowers. What I wish to inculcate is, that people who may not have stoves and greenhouses may, nevertheless, have pretty floral arrangements on their dinner-tables; and that a few flowers, arranged as has just been described, give a dinner-table a look of refinement such as nothing else can do.

A. HASSARD.

Upper Norwood.

Monanthes ariostaphis.—This is one of the most desirable of scandent succulents; it has opposite leaves about the size of, and nearly as thick as those of "Horse Beans." It grows freely in a light moist sandy compost, and if planted in a hanging-basket or pot, it droops very gracefully over the sides. It is easily propagated either by means of cuttings or division, and well deserves general culture as a window plant.—B.

THE FRUIT GARDEN.

THE BEST VARIETIES OF PINE APPLE.

THE varieties of the Pine Apple, though not so numerous as those of some other fruits, are yet sufficiently so to perplex those who contemplate their cultivation, and wish to grow only the best kinds. Out of some two dozen varieties, the following are, in my opinion, the most meritorious:

SMOOTH-LEAVED CAYENNE.—This is certainly, in every respect, the finest variety of Pine Apple in cultivation. It is a robust, compact, free grower. The leaves are quite smooth, of a dark green colour, and covered, on the underside, with a whitish powdery bloom. This is never found on sickly plants, and is always a sure indication of good health. There are two varieties of Smooth Cayenne, one with fine, broad, recurving leaves, which is decidedly the best; the other is much more narrow and erect in the leaf, and never looks so well as that just mentioned. It is one of the most reluctant to produce suckers, about which there is this peculiarity, that they never show themselves until after the fruit appears. It seldom starts prematurely, and is always certain of showing fruit when the plant is about ten months old or so. The average weight of the fruit is from 5 to 8 pounds, and its flavour, in winter and in summer, is nearly uniform, and always excellent. It swells well at all seasons, is very firm in flesh and skin, and will keep well in a cool room for at least six weeks after it is ripe. The Smooth Cayenne yields, as has been already stated, the heaviest weight of fruit from a given number of plants, and it is altogether a very excellent Pine.

PRICKLY CAYENNE.—This is sometimes taken for Charlotte Rothschild. It is, however, inferior to that variety, as well as to the smooth-leaved kind, but is, nevertheless, a fair average Pine. The leaves are narrow, tinted with purple, somewhat erect, and prickly along the margins. It is a sure fruiter, the average weight being 7 and 8 pounds. The fruit begins to colour at the bottom while the top is quite green, and, by the time the top is ripe, the bottom has frequently begun to rot. This generally occurs when too much water is given at the root. Under all circumstances this Pine must be used immediately it is ripe.

CHARLOTTE ROTHSCHILD.—This is a valuable Pine. It grows large, and requires plenty of room for development. The leaves are of a lively pale green colour, long, recurving, and thickly edged with strong spines. It is not such a free grower and fruiter as the Smooth Cayenne, but the fruit is quite equal to that variety in flavour, either in summer or winter, and it often swells to the handsome weight of 10 pounds. Like the Smooth Cayenne, it seldom throws gills from the fruit stem, and it is slow in producing suckers, a circumstance which accounts for its comparative scarceness in the country. It should be in every collection.

THE QUEEN.—This, though an old and common variety, cannot be cultivated by the inexperienced with much success. It is indeed, the most capricious and deceptive of all Pines. Though of the same age as other kinds and treated precisely like them, and though growing along with them, and as large and like to bear fruit as any of them, yet, it frequently does not do so for twelve months afterwards. Sometimes small plants will start into fruit unaccountably and prematurely; often large fruitful-like plants cannot possibly be induced to fruit, while others in all respects similar, not only produce fruit freely but every sucker on the plants shows fruit also. Rarely, even with the best of growers, does a full batch of Queens start into fruit together, nor within months of each other; half the quantity desired is often all that is obtained. I have seen plants of this variety attain a height of 5 feet. These certainly looked quite capable of bearing fruit long before they had acquired such stately dimensions, but they did not fruit until they were four years old. To induce fructification and keep the plants within bounds, decapitation is often resorted to in the case of the Queen, but seldom with any other variety. This operation consists in cutting over the plant by the surface of the soil, clearing off a few of the bottom leaves, as in the case of suckers, re-potting in fresh soil, and plunging in a strong bottom heat, where new roots are soon produced and fruitfulness is generally immediately the

result. The Queen is a moderately robust grower. The leaves are half erect, with rough spiny edges, and the fruit averages from 3 to 6 pounds in weight. In summer the flavour of a good Queen is first class, but in winter it is only about fourth rate. Suckers are produced very abundantly (as well as numerous gills) from the base of the fruit and along the fruit, stem; it is, therefore, easily propagated, but, as regards merit, I give all the preceding preference to it.

BLACK JAMAICA.—This is sometimes grown under the name of Montserrat. Its leaves are long and upright, and very dark green when ripe. The fruit is deep yellow, small, compact, and weighs heavy for its size. Its flavour at all times is exquisite, which is its principal recommendation. It is not often grown in quantity, except about Manchester and throughout Lancashire, where it is extensively cultivated, and seems to be a general favourite.

PRINCE ALBERT.—This is as yet a comparatively scarce Pine. In habit it somewhat resembles the Jamaica, and is a very fine variety. Its leaves are purplish-green, with strong spines. In shape, its fruit differs from the barrel form of the preceding in being pyramidal from the base, which is very broad; it tapers to the apex, is generally a foot in length, and from 4 to 6 pounds in weight. The crown is only about 2 inches high; it cannot be induced to grow large, and, although it would look out of place on the broad shoulders of a 6-pound Smooth Cayenne, it forms a becoming finish to fruit of its own kind. When young, the fruit is dark purple, changing, when ripe, to a beautiful reddish-yellow, and the flavour is at all seasons excellent. It is the handsomest of all Pines, and, as suckers are produced from it freely, I hope soon to see it as common as the Smooth Cayenne.

LAMBTON CASTLE SEEDLING.—This, when in commerce, will be a valuable addition to our stock of Pines. It is a strong grower, with very long dark green leaves, and fruits freely, if needs be, when the plants are small and young, which is a matter of great importance where quick returns are looked for. It surpasses all others in size and weight of fruit, average examples of which weigh from 10 to 12 pounds each. As seen growing in quantity with Mr. Hunter, at Lambton Castle, its appearance is all that can be desired. I cannot speak personally as to its flavour, but in "Fruit Culture Under Glass" it is said to be "exceedingly juicy and well flavoured." This, in the case of a fruit double the average weight of that of any other Pine, is a great gain. Others, such as Enville, Wortley's West Indian, Blood Red, Downton, Havannah, Black Prince, The King, Globe, Hurst House Seedling, Prickly and White Providence, Moscow, Thorsby, and several kinds of Queens might be enumerated; but these possess no particular merit, and are scarcely worth growing, even for the sake of variety. J. MUIR.

Effect of the Late Rains on Fruits and Vegetables in Devonshire.—We have had fine rains here this week, which have been beneficial to Grass, Corn, and Mangold crops, and for Turnip sowing. Potatoes, I have observed, have been small so far, but pretty good for eating, though they have shown symptoms of disease generally, both in stalk and foliage, and a good many of the tubers, when cooked, have been soft, white, and watery. As regards fruits, the Apple crop, after passing through all the vicissitudes of cold, hail storms, frosty mornings, and a long duration of cold biting north-east winds, is much better than was expected; there are some Apples in almost every orchard, some of which are producing a heavy crop. Taken altogether, there is more than half a crop which is now growing fast. Cherries have been pretty plentiful, but generally small, and a good many not much more than skin and stone; while, owing to the long continuance of drought, the natural food for birds got so scarce, that they devoured an immense quantity of them, more particularly the starlings and jackdaws.—JAMES BARNES, *Exmouth*.

Strawberries on the Pacific Coast.—The San Francisco papers state that the receipts of Strawberries in that city for a week or more, towards the end of May, had averaged over thirty tons daily. The greater portion of this immense quantity comes from Santa Clara county, large tracts of land in the vicinity of San Jose being devoted to the cultivation of this fruit. It is transported to the city in chests of twelve to twenty drawers. Each drawer of the twelve contains 6 lbs., and of the twenty 4 lbs. each. On May 28 chests sold at from 2 dols. 50c. to 4 dols. at the commission-houses,

the lowest price this fruit ever sold for in San Francisco. At retail the choicest varieties could be obtained for 10c. per lb. The *Chronicle* adds:—"Thirty tons of Strawberries is a large quantity; but, until a day or two past they have all been disposed of. After this, however, until the close of the season, it will be almost useless to send inferior kinds to this market, as they were yesterday thrown away. When the choicest varieties bring but 1c. per lb., inferior ones will not pay for handling. The crop is unprecedented; and, while the current prices are barely adequate to pay the cultivator for his labour, they place the fruit within the means of the multitude." The San Francisco region is an excellent one for most kinds of fruit.

The Land of Peaches.—The Delaware Peach-growers' Convention met lately at Dover, in Delaware. The Hale's Early was the finest among specimens shown, and a good crop throughout the peninsula of this variety (the earliest), is expected. They will probably form a very large part of the entire yield for the season. The Troths were also very full; but the Early Yorks did not seem so good. The Old Mixons exhibited only a very small chance for a crop. The Smocks will probably be only tolerably full. The Stump of the World made a poor show, and the Crawford's Late were about on a par with them. The Crawford's Early made a very excellent show. The Reeves Favourites looked very promising, and the Moore's Favourites here looked well. Mr. Townsend also reported that the crop for the present season would fall very far below that of last year; that, probably, there would be only one-third as many. There were about 1,500,000 baskets last year. A grower representing Smyrna and the country around, reported the prospect for a good crop in that neighbourhood as very uncertain, and a gentleman from Dover thought that the yield from this section would be very thin, in fact, almost a failure. In Kent County, Maryland, a very prolific Peach section, the crop was reported a failure. In Sussex County, Delaware, a like report was made, and the same from the lower portion of the Eastern Shore of Maryland. The estimates were then called for and the following were reported by the growers representing the different sections:—From Mount Pleasant, 20,000 baskets; Kirkwood, 10,000; Armstrong's, 35,000; Middletown, 75,000; Townsend, 25,000; Gims, 2,000; Black Bird, 5,000; Green Spring, 5,000; Clayton, 35,000; Brentford, 10,000; Morton, 25,000; Dover, 20,000; Wyoming, 20,000; Woodside, 5,000; Canterbury, 10,000; Felton, 10,000; Harrington, 5,000; Farmington, 3,000; Greenwood, 2,000; Bridgeville, 10,000; Seaford, 5,000; Laurel, 10,000; Delmar, 2,000; Salisbury, 5,000; Dorchester and Delaware Railroad, 10,000; Junction and Breakwater Railroad, 10,000; Kent County Railroad, 25,000; Maryland and Delaware Railroad, 25,000; making a total estimated shipment by rail of 442,000 baskets. It was also estimated that 158,000 additional would be shipped by water, making a total shipment from the entire Peach country of 600,000 baskets.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Vines in Pots.—At what stage in the growth of Vines in pots should liquid manure be given?—A. [It may be given with advantage after the berries are fairly set, and have begun to swell, but as soon as there is the slightest indication of change in their colour, the supply should be discontinued, or it might injure the flavour of the fruit when ripe.—Ed.]

Watering Pine-apples.—I send you a sample of our Pines. The plant from which the fruit sent was cut was watered copiously up to the last moment; but I must state that our plants have abundance of roots and leaves, both broad and thick, that do not leave any idle moisture about the roots. I submit the specimen for your opinion as to its appearance and flavour.—J. THOMPSON, *Worthy*. [Along with this came a noble Queen Pine, well coloured, and weighing upwards of 1 lbs. As to quality, it was pronounced by one of the best judges of Pines in Covent Garden to be excellent.—Ed.]

Peach Trees Dropping their Buds.—The case related by "G. S." at p. 548, Vol. V., of THE GARDEN is a peculiar one, but I have an impression that if he knew all the particulars, it is probable that the falling of the buds of the particular tree in his orchard house would be found to be due to something else than the imperfect maturation of the wood, which seems to be a matter of guess work. Ill-ripened wood can be detected at a glance. If this is the cause, how comes it that only trees under glass suffer the most? and that out-door Peaches are seldom or never affected at all in that way? The few trees we have here out of doors never ripen their wood more than partially, and yet they never drop a bud, so far as I have ever noticed. In fact, immature buds are the least likely of any to drop, so that the case cited by "G. S." must be explained in another way.—J. S. W.

Packing Strawberries.—Strawberries are the most difficult of all kinds of fruit to pack safely. Wrapping each fruit in a leaf is a good plan, but deft fingers only can perform the operation without bruising the berries. We like to pull them off the plants by the foot-stalk, and to lay them in the box in the same way, simply placing a flaccid Strawberry leaf between the berries. In this way they can be wedged as tightly together as is needful. The boxes should be 2 inches deep, and before packing a thin layer of cotton-wadding should be laid on the bottom, and on this soft Vine-leaves; above the fruit, nothing binds so well as the soft Strawberry leaves before mentioned; and above, layers of cotton or leaves to keep all in their places. It is very important that the Strawberry leaves for packing should be gathered some hours before they are wanted, and allowed to dry and flag in the fruit room: leaves freshly gathered are altogether unsuitable.—*Gardener*.

THE INDOOR GARDEN.

WINTER MIGNONETTE.

Few flowers are more esteemed in winter and early spring than Mignonette. Although it is not a delicate plant, yet it is not generally seen in the perfection to which it might be brought by the simple method of culture which I am about to describe. To flower at or soon after Christmas, the seed should be sown in the beginning of August, in pots of any convenient size. The soil should be good loam, moderately enriched with rotten dung, and kept open by a pretty liberal intermixture with old mortar or lime rubbish. It is essential that the pots be thoroughly drained, and upon the drainage a handful (more or less, according to the size of the pots) of one-year-old pigeon's dung should be placed. After sowing the seed, set the pots where they will not require frequent waterings, too much moisture being extremely injurious to Mignonette; for this reason, therefore, it will be safer to place the pots in a frame or pit, where they may be covered by the lights in rainy weather. As the plants increase in size, they should be gradually thinned, ultimately leaving three or five in each pot. The principal point to be attended to now is judicious watering; by this I mean giving water only when the plants really require water, and then in sufficient quantity to moisten the whole of the soil—not dribbling a few drops over the plants to-day to prevent them from being dry to-morrow—a practice too much followed with plants in pots. Pinch off any premature flowers that may appear, keep the pots free from weeds, and far enough asunder to prevent the plants from being crowded, and when they are removed to winter quarters, set them near the glass in an airy situation. A few of the plants might be placed in an intermediate house, or other situation rather warmer than a greenhouse, to come into bloom a little earlier than the rest. I have recommended the seeds to be sown in pots, which is the method I prefer; but, if more convenient, a sufficient number of self-sown plants might be taken up and potted, only a few extra should be put in to allow for casualties, as the Mignonette transplants badly. The best Mignonette I ever saw was treated in this way; but, as it is not everyone who can procure pigeon's dung, I may add that guano will be found an excellent substitute. This admirable fertiliser must, however, be applied in a liquid state, and not before the pots have become well filled with roots, when a small quantity of guano, given at intervals of a week or so, will increase the vigour of the plants in an extraordinary degree. A second crop might be sown in the beginning of September, and managed in the same manner. Single plants will attain a large size in 6 or 8-inch pots, if the main branches are pegged down as they grow and the flowers are kept pinched off for a time.

G. M.

ECHEVERIAS.

In your issue of June 20 (p. 531, Vol. V.) you have given a long list of Echeverias, in which there are several errors, both as regards nomenclature and description. I shall, therefore, venture to rectify them, and, in taking them as they come, where I make no remarks it may be presumed that the original information is correct. *Echeveria abyssinica* is not an Echeveria, but a *Sempervivum*. *E. agavoides*, of this *E. yuccoides* is a synonym. *E. atropurpurea*, the leaves of this are said to be oval-acute glaucous, but they are canaliculate narrow, 4 to 6 inches long, and not glaucous. *E. bifida*, this is a synonym of *E. stolonifera*; in the remarks on *stolonifera* it is said to require a dry and warm temperature; it is, however, equally as hardy as *E. secunda*, which it much resembles, if kept dwarf, but it will grow from 6 to 12 inches in height. *E. calephana*, is said to be, probably, a garden name for *acutifolia*, a kind to which it bears no resemblance; but it is very nearly related to *E. lurida*, only not so metallic in hue. *E. carinata* is a hybrid between *E. metallica* and some other sort, and is not worth growing. *E. farinulenta* is a garden synonym of *E. farinosa*. *E. globosa*, this is distinct from *E. glauca*, and is the same as exhibited by Messrs. E. G. Henderson under the name of *eximia*; it is a better plant than *glauca*, and has a bluish tint, the leaves are concave. *E. hookeri*, synonym *Pachyphytum roseum* (Hort.). *E. laxa* is a variety of *E. californica*, but the foliage is not quite so glaucous as in that kind, and it is more depressed. *E. misteca* is the same as *E. nodulosa* (Baker). *E. Pfeisendorffii* is *E. stolonifera*. *E. scaphylla*, this is said to form "a stemless well-

furnished rosette of leaves, and to be a good subject for ornamental edgings;" the plant is, in reality, however, a very strong grower, forming a mass of green foliage 1 foot through, and from 12 to 18 in height; therefore, quite unfit for edging purposes. *E. spathulifolia* is *Sedum spathulifolium*, and *E. villosa* is the same as *pubescens*. In the notes on cultivation, vegetable mould and peat is recommended, to be mixed with loam and sand. I have, however, always found that Echeverias dislike peat, they avoid it and delight in loam and a mixture of burnt ballast. When at Mr. Wilson Saunders's we once spoilt our Echeverias through giving them peat, especially *E. farinosa*; but in the compost just named I can treat it as the others, giving it plenty of water. As to propagation, they strike as freely as *Pelargoniums*; the best plan is to cut the tops off, which are found to make excellent plants; the stems, afterwards, push out shoots freely, except, perhaps, *E. pulverulenta*, which is a dangerous subject; if cut down, it strikes tardily, and the old stem dies.

J. CROUCHER.

Cereus speciosissimus as a Climber.—This is a free-flowering and attractive plant when grown in a pot, but to see it at its best it should be planted out and trained up the sunny wall of a conservatory or warm greenhouse. In the conservatory at Little Dalby Hall, near Melton, the back-wall is completely covered with this showy flowering plant to a height of about 12 feet, and when I saw it, a few days ago, there were two or three hundred flowers either fully expanded or yet to open, while many had already fallen off. In addition to the flowers, the plant is made to serve as a stock for *Phyllocactus Jenkinsonii* and one or two *Epiphyllums*, which promise to succeed well thus treated.

Cape Pelargoniums at Kew.—In the Heath-house at Kew there is now quite an attractive display of these showy plants, many of which, notwithstanding their old-fashioned aspect, deserve a place in the greenhouse or window garden, where, under ordinary treatment, they will bear white, rosy-purple, scarlet, or crimson flowers in profusion. In times gone by Cape Pelargoniums used to make their appearance on our exhibition tables, but now they are seldom or never seen on such occasions. Among those now in bloom at Kew, the following are the most conspicuous, viz.:—*P. selectum*, a free-growing variety with Oak-shaped foliage and trusses of vivid purple flowers; *P. pulverulentum*, a variety having swollen stems and thick deep green leaves, something like *Begonia roseiflora*; its flowers are of a deep velvety maroon, nearly black, each segment being margined with dull yellow; *P. elatum*, a kind with small serrated, oblong, glaucous leaves, set on long slender petioles, and bearing conspicuous flowers an inch across, arranged in loose trusses; the lower segments are white, the upper vivid crimson veined with black; *P. ardens majus*, a showy Oak-leaved variety, having trusses of deep scarlet flowers, the upper segments of which are nearly black and quite velvety in appearance. These Cape kinds, like other Pelargoniums, may be readily propagated by means of cuttings, and they like a fresh open compost consisting chiefly of sandy loam.—F. W. B.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Ozothamnus glomeratus.—This pretty little composite shrub has long slender branches, bright green oblong or ovate sharp-pointed leaves, and dense glomerate heads of whitish flowers; the latter are most deliciously scented, and the plant is well worth a place planted out either in the cool conservatory or winter garden. It is a native of New Zealand and tolerably hardy.—J. Q. H.

Genista prostrata.—This is just now in beautiful condition; its rich golden Pen-shaped flowers being borne profusely on slender decumbent branches. It does well treated as a pot plant in a cool greenhouse or conservatory, or it may be planted on a sheltered portion of rock-work in the outdoor garden, where its bright blossoms render it very effective.—J. B. Q.

Anthurium Scherzerianum with double spathes.—A small seedling of this fine stove plant in the Orchid-house, at Tweed Vineyard, has produced a double flower, i.e., the first bloom which opened had a double spathe. The spathe was the same as that of single blooms. Other flowers which have since expanded on the same plant are single. The double one may be a monstrosity, yet it indicates the possibility of obtaining a double variety.—M.

Mimosa prostrata.—This forms an elegant climber or trailer in a cool conservatory. It grows vigorously when planted out in almost any porous compost, and should be trained up columns or pillars and allowed to fall down gracefully from the top; so treated it is very effective, its slender pink shoots being beset rather closely with fresh green pinnate foliage, among which its globular heads of pink flowers are often conspicuous. It is readily propagated by means of cuttings, and seed is borne in abundance on established plants.—B.

Dianella tasmanica.—Dianellas are for the most part pretty blue-flowered Grass-like plants well worth culture in cool greenhouses or conservatories, not only on account of their spreading panicles of cerulean flowers, but more especially for their bright blue berries which develop themselves after the flowers have faded, and which remain ornamental for several months in succession. They all grow freely, but *D. tasmanica* is one of the best of the group. They grow and blossom well in a fresh compost consisting of loam and leaf-mould, sufficient sand being added to keep the whole in a porous condition. They require a liberal supply of moisture all through the summer months.—B.

FORMALISM AND FOLIAGE.

WE wish to condemn a practice which has been, by some, accepted as a safe one, namely, that of blending palatial architecture with garden scenery, by making those portions of the gardens in close juxtaposition with the architectural lines of the terrace and main building exhibit a formal and geometric character, by the introduction of a preponderance of lines running parallel with those of the structures with which they are closely associated. Even low clipped hedges of ever-green or deciduous shrubs have often been resorted to, in order to give, as it were, more emphasis to the linear effect of this part of a garden. That such a principle is injurious rather than advantageous, is rendered evident in the present instance, by the pleasing effect produced by means of the partial concealment of the architectural lines of the terrace, by the irregular growth of a few judiciously placed shrubs, as shown in the accompanying illustration. The effect thus

shrubs, whose growth does not exceed a moderate height. Forest trees would clearly be out of place so close upon a highly decorative façade, and should be, when in front of such a structure, relegated to a considerable distance, where they would so group with the building, when seen from a stand point still more distant, as to form a pleasingly combined picture, without appearing to intrude upon such an architectural composition—the sky lines and upper part of which are generally intended to be seen, uninterruptedly, from a conveniently near point of view. Such a building may, however, be flanked with the foliage of tall trees with great advantage, which would afford support (as shown) to the general forms and aspects of the building by its dark masses of pleasingly irregular form, and of rich and distinct hues of colour; which not only impart extra value to the light one-toned line of the building, but blend it into the surrounding scenery with great grandeur and reposefulness of general effect. Clipping of trees

Terrace Garden, with unclipped Vegetation.

realised is undoubtedly good, and shows, beyond the power of cavil, that well planned and artistic interruptions to the continuous formality of architectural lines by the occasional introduction of gracefully-growing shrubs at well considered points, are of the greatest advantage in producing an agreeable variety of form in the general composition; both the regular and the irregular forms gaining greatly by their close juxtaposition. The wild natural grace of the shrubs, whose general growth is of pointed and rising character, being seen to great advantage against the horizontal lines of a light background of stone or marble, while the mouldings of the terrace cornice-work are appreciated with double advantage after their temporary concealment. These advantages would not have been obtained if clipping, and other kinds of formality had been resorted to in the foliage. It should be observed that the foliage near the terrace, which has been made use of in the present instance for the purpose of varying what would otherwise be a monotonous continuity of straight lines, is that of

and shrubs to make them harmonise with architectural forms has for generations been an orthodox practice, but it is none the less a barbarous and needless one. H. N. H.

GARDEN LANDSCAPES AND FLOWERS IN THE WATER-COLOUR EXHIBITIONS.

ONE of the most attractive of the smaller pictures in the present exhibition of the Institute of painters in water-colours, is a spirited study of an old gardener, by Mr. H. B. Roberts. The work has evidently been executed with a rapid and skilful brush, and the result is a free-handed and very artistic production. The expression of that kind of good humoured sagacity which arises from being connected with flowers and fruits, and their culture, is well hit off in this clever sketch; as is also the expression of the honest, perhaps rather self-satisfied, conviction that the said flowers and fruits have always been

the finer and the better for his tending. The fine old face is a very index of the seasons, and the weather-wisdom of over three score of years; and a twinkle in the eye, shows plainly enough that the old gardener is brimful of knowingness upon all such horticultural matters as have come within the range of the plodding practice which has been the business, and evidently the very pleasant business, of his life—the successful minding of his master's flower garden, and kitchen garden, and greenhouse too, with possibly a bit of a stove for a few specialities. There is also a quaint puckering about the lips of the weather beaten, but hale and hearty, countenance, which indicates that a supply of good racy garden talk is ready to hand, to any extent, if he should be asked any questions when he takes up to the house the basket of ruddy Apples, nicely trimmed Cabbages, and other esculents which he is carrying under his arm; I commend him to the notice of the always witty and instructive author of the "Six of Spades," and I only wish the original of this capital study, for it must have been done from the life, were going the round with me among the pictures, for the sake of hearing a few of his remarks on flower painting, good or bad, and ancient Peaches and Melons and Grapes as they appear on paper or canvas, in this year's exhibition. I fancy he would deem none of the flower or fruit portraiture flattering to the originals, especially if they had been raised by himself, and that he might break out with— "Well, I'd never have sent such a bunch of Grapes as that to a show, or exhibition, or whatever it may be called; and as for the Roses—why, I should have been ashamed of 'em."

Not being able to obtain the assistance of my old garden friend, I must arrive at conclusions in my own way—and am induced to admit to myself that it is not always the most perfect show flower that makes the best model for a picture, nor the most perfect bunch of Grapes that is the one which ought to be painted, for would not every blemished berry on a bunch of Muscat of Alexandria, intended for exhibition, have been carefully snipped out, and the speck of brown or crimson, which in a painted bunch would be of the highest artistic value as a relief to the monotony of the somewhat opaque, glaucous colouring, have been made to disappear. I think I should be able also to show to my friend, the old gardener, that in what may be termed floral landscapes, if by good artists, there is always something new and refreshing to be learnt. For instance, in the picture by Mr. Albert Goodwin in the exhibition of the society of painters in water-colours entitled "The Alpine summer," such vast stretches of flower-colour are shown, as make the patches of blue, red, or yellow in any English garden as yet planted, shrink into pinenshion work. In the Alpine summer there are far extending streaks, and broad masses of pink, blue, yellow, orange, and other tones, caused by the profuse flowering of Gentians, Mountain Anemones, Trefoils, Wild Irises, Campanulas, Cyclamens, Trilliums, Orange Lilies, and other flowers, in masses measuring whole acres in extent. Here then, is Nature's method of producing grand effects, upon a large scale, which might be artificially imitated, wherever sufficient space could be devoted to purely decorative purposes. Mr. Goodwin, who evidently feels intensely the beauty of Alpine scenery when rich with its gorgeous tints of spring and summer, has another study of Alp-land, which he calls "The Alpine Rose," in which large spaces, as though vast rosy clouds were resting on the flanks of the great green hills, are en crimsoned by the deep rose colour of *Rhododendron ferrugineum*. The plants grow as thickly together as Heather, and the whole mountain is made glorious by them. Mr. Goodwin, in his enthusiasm, quotes the antique poetry of the Bible to express his admiration:—"The wilderness, and the solitary place shall be glad with them."* That something of the kind might be produced in English park and garden scenery is proved by the existence, in England, of similar effects in places where, however, they are rarely seen, and where they do not minister to the interest and beauty of landscape gardening, or to that of broadly-treated park effects. I know, for instance, many woods which, in April, are so closely carpeted with a profuse and closely-grown crop of wild blue Hyacinths that Nature's flooring is one continuous mass of blue. I also know many meadows, even in the metropolitan counties, where, in early spring, acres of the wild single Daffodil

cover great expanses with soft pale gold, beautiful to the artist's eye, but "disgusting" to that of the farmer; "for," he says, "they spoil his pasture, and the cows don't like 'em." In Scotland there are upland spaces of enormous extent, and plains, too, which are so densely clothed with Heather that, in the autumn, they produce an effect of rosy or lavender-hued monotone, as continuous and complete as though the whole district were artificially clothed in some rich fluffy material of one or other of those colours. The richness of the effects of colour of these broad moorlands, heightened or deepened according to the natural undulations of the land, is rendered highly picturesque by the dark trunks of Pines or bright white of silver-barked Birches, that rise from this deep carpet-work of pinky-purple that spreads far and wide. It is thus evident that such scenes as that of Mr. Goodwin's Alpine summer might be created in any part of England where land can be conveniently spared for the purpose. Mrs. Harrison has a little glimpse of scenery called "View at Holmwood," in which the foreground is entirely composed of a stretch of closely-flowering Primroses, showing how closely-planted masses of wild flowers, each kind occupying to itself a large continuous space, may be made wonderfully effective and very beautiful in the garden landscape.

The flower-painting in the water-colour exhibitions, with the exception of two or three real gems of art by Mrs. Duffield, is not strikingly represented this season. It by no means reaches the high level of several flower subjects, treated in oil, in the Royal Academy exhibition. Mrs. Harrison's compositions at the institute are, for instance, as a rule, too indefinite in character. The extreme delicacy of flower-forms and tones is not sufficiently studied, two large compositions being especially remarkable for these sins of omission. Another lady artist, of the same name, in the "society's" exhibition exhibits flower subjects which are all, more or less, open to similar objections: a large group of *Convolvulus* major being, perhaps, the more attractive of these works. In Mrs. Duffield's works at the institute, on the contrary, delicately accurate definitions of form, and a refined appreciation of the lightest shades and tones of colour, are always well observed; a group of *Althæa frutex*, with other flowers (No. 291), and Peaches and Sweet Peas (No. 223), being very beautiful examples of this lady artist's best manner. Only one really remarkable example of fruit-painting is to be found on the walls of either exhibition; it is the work of J. Sherren (No. 149), at the institute. The composition is somewhat affectingly entitled "Bread and Wine," and consists of two bunches of Grapes, one of Muscat of Alexandria and the other of Black Hamburg—both such as the most accomplished gardener need not be ashamed of exhibiting. They are exquisitely finished, and the general treatment strongly calls to mind some of Hunt's masterpieces in that style of art. Beneath the Grapes lies a handful of ears of Wheat; and at the back is the sacramental gold plate, a salver, and a chalice, painted as finely as Lance's well-remembered piles of plate in his famous Gil Blas subject, "Rolando's Cave."

In the figure subjects, in which flowers or fruit are made to play a conspicuous share, are a few pictures which ought not to be passed over without a passing word of comment. On the "society's" walls Mr. Smallfield has a charming twilight picture, which he calls "Evening Primroses." A lady of the Elizabethian time, in the picturesque costume of her day, sits thoughtfully on a stone seat as the shades of evening gather, and the night-flowering *Oenothera* is unfolding its pale yellow flowers, that shine like stars in the increasing darkness. Another subject is, a lady placing a small vase filled with Primroses upon a table, and bends over them to inhale their sweet spring odour. I forgot to mark it in my catalogue; it is a little picture worth looking for. At the institute, a large work, "Vintage Procession in the Campagna" (No. 181), by Guido Bach, has a well painted basket of Grapes, an offering to the Virgin; and a child has wreathed its beautiful Italian head with twisted sprays of Vine, with a wild grace, highly suggestive as a model for the treatment of that kind of feature in any kind of festal decoration. There is also a picture, by E. K. Johnson (No. 44), called "Summer," in the society's exhibition, in which growing flowers in a half-wild garden (tended by a very pre-Raphaelite lady), are very carefully and effectively treated, especially the Sunflowers, Hollyhocks, Cam-

* Isaiah.

pannulas, and Sweet Williams. Many other subjects are worthy of a word of comment, but my allotted space is more than filled.

A GARDEN LOVER.

THE KITCHEN GARDEN.

ASPARAGUS CULTURE IN LONDON MARKET GARDENS.

This is a remunerative crop in good seasons, but in late cold springs, the beds do not begin to bear until May, thus materially shortening the cutting season, which must be discontinued in good time to permit a full growth of the shoots before the end of the autumn. It must also be remembered that this crop occupies the ground for two entire years without yielding any pecuniary return: on the contrary, in addition to the ground-rent, a vast expenditure is incurred in the way of manure and manual labour. Although it begins to repay a little in the third year, it is not until the fourth season that it begins to fully pay for the trouble and expense of growing it. During these three years the same ground would have yielded six, nine, or twelve other crops, each of which would amply have rewarded the cultivator for his pains. Asparagus, too, allows the ground no rest, for even in a young state it is a gross feeder; the question therefore, whether in the long run it pays well or not, is rather a difficult one to answer.

First Year.

Asparagus may be raised from seeds saved in autumn, and sown in rows from 18 inches to 2 feet apart in February. Between lines of young fruit trees, or between rows of fruit bushes or Moss Roses is the usual place in which the seed is sown. The less shaded, however, the ground is the better; but open ground in market gardens is too precious to be devoted to this crop the first year. I have, however, seen a field at Isleworth devoted to it; Potatoes, Cabbages, and Brussels Sprouts being set between the rows. Great attention is paid to the young Asparagus the first season, in the way of hoeing and cleaning, and thinning a little if too thick; and the succeeding spring, provided the plants have grown strongly, they are transplanted permanently.

Second Year.

Now is the time to consider the kind of plantation to make, and the distance apart of the rows, not the beds, as would be the case in private gardens. Market gardeners seldom make beds now-a-days, and those that do exist are gradually giving place to the single-row system. Mr. Steel, of Fulham, had lately some Asparagus beds containing three rows, planted 2 feet apart from one another, and from the centre of one bed to that of the next was 9 feet. He had also a few other beds with two rows in each, the same distance apart as in the case just named, but in this instance the beds were only 7 feet from centre to centre. Mr. Dancer, of Fulham, and some growers at Barnes and Mortlake, still have beds on the same principle. These beds, in addition to the Asparagus, yield three rows of French Beans in early summer, two rows of Coleworts in autumn, and three rows of the same in the alleys between them. The recognised mode, however, is to plant Asparagus in single rows 5 feet apart; but many prefer even a greater space than that between the rows, for Mr. Jessop, at Chiswick, has his Asparagus in single lines from 6 feet to 8 feet asunder, and I must confess that I never witnessed such fine plantations. The 5 feet wide ridges, however, being the most universal, we will suppose that to be the system adopted. The ground for the crop having been trenched and heavily manured late in autumn, it may be marked off into 4 feet wide beds with alleys intervening 1 foot wide. In these beds sow Radishes in December or January, as convenience permits; and in March or April, after removing the protecting litter from the alleys, dig them and plant therein the Asparagus about 15 or 18 inches apart. The Radish crop will soon be removed from the beds, which may be cleaned, slightly dug, and Beet sown therein, or Onions or Leeks transplanted on them, and which will occupy the space till autumn, when they too may be cleared off and Coleworts or Wallflowers planted in their place. Other modes of cropping the space between the Asparagus

might be resorted to, but that referred to and practised by Mr. Pocock between Kew and Mortlake I consider the best. Summer Cauliflowers intercropped with Lettuces occupy much room, and French Beans, if used, would necessitate so much trampling of the ground in the operation of gathering, that the Asparagus would be checked at the root and be liable to injury of the stem from breakage. An open position is also of great importance, for the more the plants are under the influence of the sun the stronger will they grow, and the sooner in the season will they yield "grass." Hoeing the surface soil and keeping all clean includes all further requirements until the end of October or 1st of November, just any time after the sprayey shoots turn yellow, when they are cut over an inch or two above the ground. As soon as the crops between the rows are removed the ground is heavily dressed with light manure, such as that used during the summer for growing the frame Cucumbers on, and which is dug into the ground.

Third Year.

This year the Asparagus is strong enough to produce a partial crop for market, consequently the mode of culture depends on whether the grower intends to have blanched or green "grass." The latter is sometimes desired as being the best for the plants, and there is a small demand for naturally coloured shoots. In this case, therefore, the ground is intercropped as in the previous year, an effort being made to change the subjects if possible. If the soil was cleared and prepared in good time, Potatoes might be planted this year; or Seakale, Spinach, or Turnips might be used instead. In case of the ridging system being preferred, the rows are earthed up a little from the broad spaces between them; but not so much as they will be in future years. On each side of this ridge a row of Cabbage or French Beans is commonly sown. Cutting begins immediately the heads appear at the surface of the soil; but it is not practised severely this year, for some shoots are allowed to grow unchecked about a fortnight after cutting begins, and it only lasts for about four weeks, when all shoots are permitted to grow. Some market gardeners scarcely cut any the third year, whilst others do so rather severely. At the end of the season the tops are cut over, and the ridges are levelled and otherwise treated as follows:—

Fourth Year.

This is the first main cropping year; consequently, what is done to the plantations this year is merely repeated in after years, until the plants become weakly and the rows patchy, when the plantation is broken up and cropped with other subjects. On the 1st of March, provided the weather be pretty dry and no frost in the ground, the rows are earthed up from the intervening spaces after having had their surface previously forked over. The coating of soil is about 10 inches deep; and, when all is nicely rounded off and finished, the ridges appear like a series of Potato pits, or broad Celery ridges, rounded at the top and void of plants, and are altogether about 24 or 36 inches in height. The ridges are cropped, as previously stated; and about the 1st of April the whole surface soil is loosened with a hoe and rake, so as to permit of an easy egress of the shoots. In ordinary seasons cutting begins about the middle of April, and last for ten weeks; but, in bad springs, it is sometimes May before it commences. It is discontinued about Midsummer Day, and is rarely practised until July; but a little longer allowance is made in the event of a late spring. During this particular year, however, the cutting is not quite so severely performed as in after ones, when, from the time it begins until it ends, not one head escapes the knife. Small and great are cut, until the 21st of June, or thereabout, when all are allowed to grow unchecked excepting in the case of some small sprayey shoots that are better removed than left. In the alleys Coleworts are now planted, either two or three rows; and in many cases, too, the ends of all the ridges, and where any blanks occur, are similarly made up. Sometimes there is also a row of Coleworts planted along the side of the ridges when the French Beans have been removed; but, if Beet had been sown there, it will remain until the autumn. I have also seen Nasturtiums grown on the same sites for yielding cut flowers and seeds for pickling. When cutting-down time comes, all the unberried

"grass" is cut and laid in heaps together, whilst the berried stalks are kept separate. The former is carted home to the fire-heap or dunghill, or is kept for a foundation to hot-beds; and the latter are kept for seeding purposes in a dry and airy shed. After being stored there for a while, until the seeds become ripe and firm, the berries are separated, washed, and dried, bruised and rubbed in sand, afterwards washed again to clean the seeds, which are spread out to dry, and then stored until sowing time. Before the time of thus clearing the ridges most, if not all, the Coleworts will have been marketed; therefore draw the surface soil of the ridges into the alleys; and into these dig it rather deeply. Plant immediately some of Cock's hardy green Coleworts; no matter how big and lanky the plants may be, they will soon take to the soil, and be marketable by the end of February; then proceed with the last year's routine of ridge-making.

Plantations last in good bearing condition for six or seven years, after which time blanks appear; therefore it is considered more profitable to break them up than to keep them longer. When such is the case, they are cut from during the last year of their existence as long as the result will pay for the trouble; and if it is thought that the roots will afterwards be of any use for forcing, they are permitted to occupy the land till November, when they are lifted for that purpose; but, considering them to be too poor for that end, they are uprooted at once, the ground levelled, manured and dug, and planted with Broccoli or Cabbage. The ordinary long saw-knife is the instrument used in cutting, and the men and women employed in the market gardens are great adepts in its use. They slip down the blade alongside of the shoot, and with a peculiar twitch sever the stalk from the crown without injury to the latter or the advancing shoots. In cutting, the "grass" is laid in little heaps on the tops of the ridges, until one course of rows has been gleaned from; they are then collected into baskets, conveyed in a cart or barrow to the sheds, where they are washed, tied into bundles of a hundred (105), and are that night, or early next morning, sent to market. Mr Dancer, of Chiswick, one of the best and most experienced of market gardeners, has a very strong-growing variety of Asparagus, called Giant, a kind which, when exhibited by him some time since at South Kensington, was awarded a first-class certificate. Mr Dancer grows no other sort than this, and his stock of it, as yet, is rather limited, but I believe that he has saved all the seed he possibly could gather, with the view of its extension. As early as the beginning of November, the French growers begin to supply our markets with Asparagus, very much stronger, and indeed earlier, than our own gardeners could produce it; and this has so materially altered the price of and demand for English-grown Asparagus, that the Fulham growers and others, farming very dear land, are continually reducing their plantations, whilst some have entirely done away with Asparagus to make room for quicker-growing and more remunerative vegetables. Mr. Taylor, of the firm of Webber & Co., Covent Garden Market, informed me that the dealers there have no trouble whatever in getting a thousand bundles (one hundred heads each) at a time of forced Asparagus from the growers in the vicinity of Angoulême, and other Asparagus-growing districts of France. The French Asparagus, too, which is blanched, and about 15 or 18 inches in length, is much stouter-stalked than that grown in England; consequently it demands a higher price than the latter, the usual price varying from 15s. to 35s., or even 40s. a bundle according to the season, quality of produce, and demand for the commodity. F.

ARE NOT ONIONS TOO MUCH THINNED?

By thinning the crop out well you will have large Onions, and in fine seasons probably well ripened; but when a plentiful crop of good sound keeping Onions is the object, it is a mistake to thin them too much. As a rule, small or moderate-sized Onions are the best ripened, and a small Onion is just as good in a culinary point of view, as a large one, if not better. For instance, small well-ripened Onions are preferred for pickling purposes, and to secure these it is the usual practice to sow the silver-skinned variety thickly, and leave them unthinned, and in this way "button Onions," as they are called are produced. By thinning the plants out we would only get thick necks wholly unsuitable for the purpose. Long-keeping qualities are very much

sought after by the Onion grower, and it is well known that well-ripened samples only will keep, and these are more certainly secured by leaving them pretty thick in the bed. To leave the plants 7 or 8 inches apart, as is generally recommended in gardening books, is a mistake, unless Onions for exhibition only are required; but where sound bulbs—say about as broad as the mouth of an ordinary tea-cup—will satisfy, leave the plants close enough together to touch each other when they attain that size, that is supposing them to be sown in rows 7 or 8 inches apart, as Onions always should be sown, in order to facilitate the clearing and stirring of the ground. If sown broadcast, then the plants should have a little more room. This is my practice, and a plentiful and sound crop of Onions is an important matter with us, where they are used every week by the bushel. When our women thin the crop they have orders to leave them about the length of their forefingers apart, and by autumn the ground has the appearance of being fairly thatched with Onions, of a size and quality fit for any culinary purpose. Cottagers who generally have not too much room in their gardens often crop thicker than is here recommended. Two years ago I saw a bed of yellow Danver's Onions in a cottage garden that would have astonished thin croppers. The rows were only 5 inches apart, and the plants from 2 to 3 inches, and the bulbs fairly clustered over one another, and literally covered the ground—very nice samples, and thoroughly ripened; for I kept samples of them till June the following year; and Danver's Yellow, though a first-class Onion, is only a second-rate keeper. In order to satisfy oneself on this matter, let anyone leave a thick and a thin row together, and weigh the produce at harvest time.

J. S. W., in the Field.

The Kerguelen Cabbage.—"The plant abounds with essential oil; and, when cooked, the Cabbage tastes like tough Mustard and Cress. Being a powerful antiscorbutic, it is invaluable to the crews of ships touching at Kerguelen's Land. Dr. Hooker says:—"During the whole stay of the Erebus and Terror in Christmas Harbour, daily use was made of this vegetable, either cooked by itself or boiled with the ship's beef, pork, or Pea-soup. The essential oil gives a peculiar flavour, which the majority of the officers and the crew did not dislike, and which rendered the herb even more wholesome than the common Cabbage; for it never caused heartburn, nor any of the unpleasant symptoms which that plant sometimes produces." The sole representative of this genus of Cruciferae is *Pringlea antiscorbutica*, a remarkable Cabbage-like plant confined to insular Kerguelen's Land, and hence often called the Kerguelen's-Land Cabbage."—Mr. A. Smith, in "The Treasury of Botany." The genus is characterised by its oblong seed-pods being composed of two convex or boat-shaped valves, without a partition between them; and by the seeds, which are numerous and in two rows, being heart-shaped at the bottom, but prolonged into a short beak at the top, and having accumbent cotyledons. The plant has a thick round root, often 3 or 4 feet long, and 2 inches in diameter, which lies along the ground, and bears at its extremity a large Cabbage, closely resembling the common Cabbage of this country, having a dense white heart and loose green outer leaves: its flower-stems grow out from below the principal leaves, and are from 2 to 3 feet high, with their lower part more or less leafy.

Effect of Camphor on Flowers and Seeds.—Before the beginning of this century, Dr. Benjamin Smith Barton, of Philadelphia published some experiments in which cut flowers or slips in water, which were about to fade or wither, were revived for a time by putting camphor in the water. He compared its action to that of spirituous liquors or opium upon animals. We think the idea and the practice have not wholly died out in this country, although very warm water is the commoner prescription now-a-days. Dr. Vogel, of Munich, has been trying these experiments over again, and he finds that camphor does have a remarkable reviving effect upon some plants, although almost none upon others, and that it quickens the germination of seeds.

Whalebone Labels.—With reference to the note and illustrations of this (see, p. 531, Vol. V.), permit me to say, that no label which requires handling, however little, before the label can be read, can ever be worthy any serious attention. In Italy a written label is thrust into a hollow Arundo stalk, fitted with a cap. To read the label, this cap has to be taken off and the paper unfolded. It is again folded up, the cap put on, and the reed thrust in the ground. It is clear that the persons who invent or tolerate such labels have no notion of the points required in a good label. The first of these is, that the writing should be easily read as one stands before the plant or tree, and without touching the label in any way, or even turning the head, which is necessary with labels written vertically.—CLAUDE.

THE LIBRARY.

A MANUAL OF BOTANY.*

Books on botany, both elementary and advanced, and from well-qualified authors, too, have issued from the British and Continental press in such numbers of late years, as to well nigh rival those of the French and German grammars which are to be met with, in almost endless profusion, in our educational establishments. It would be idle, however, to suppose that any one of these treatises on botany has yet exhausted the subject, or even contemplated its final exposition. When the broader questions of the true limitations of families, genera, and species shall, at some dimly distant period, have been finally resolved and universally accepted, there will still remain the vast field of microscopic investigation, in conjunction with that of chemical analysis, to yield to the persevering student fresh germs of thought, and fresh triumphs over the unsolved mysteries with which many of the phenomena of plant-life are still invested. As a valuable contribution in this direction, we welcome the recently-published work of Dr. Robert Brown, which forms the subject of our present notice. Of numerous important questions which, of late years, have occupied the minds of the most distinguished physiologists of various nationalities, it affords the solutions which, up to the present, have been arrived at, and these published results of the convictions of many of the most profound thinkers, laboriously collected and skilfully compressed into a single volume, is a step in advance, in the interests of botanical science, which we hail with unmingled satisfaction. Our readers will, perhaps, form some idea of the vast amount of the deductions of modern scientific research presented in this work, when they learn, from the author's preface, that "upwards of 1,200 separate papers and treatises, in German, French, English, and, to a less extent, in Danish, Swedish, Dutch, Spanish, and Italian, have been consulted, often without a greater reward than to obtain a single fact, which the exigencies of space have compelled to be relegated to a foot-note or a parenthesis." It would be obviously impossible, within the limits which our space allows us for literary

notices of this kind, to make very extensive extracts from the book. We must, therefore, content ourselves with recommending it warmly to our readers, appending the following brief extracts and illustrations, as examples of the manner in which the author has treated of the anatomy and physiology of flowering plants. It may be seen that the illustrations, which are 359 in number, are executed in a very good style.

Carlina subacaulis, one of the Compositæ, distinguished by the large development of the scales of the involucre. Fruit, *b*, terminating in a pappus; *a*, Tubular flower, surrounded by its aigrette-like calyx (pappus); *c*, Magnified view of one of the "hairs" of the pappus.

—They are generally attached to the receptacle horizontally, leaving, when detached, a cicatrix shaped like the are of a circle or a horse-shoe. In the mode of insertion of the sepals there are,

The Papaw (*Carica Papaya*), the type of the order Papayaceæ. 1, Whole plant; 2, Young plant; 3, Flowering branch magnified; 4, Flower-buds; 5, Baccate fruit, cut open to show seeds loose in the pulp.

Pappus or Aigrette.—In the order of the Valerianaceæ, and in most compositæ, the calyx is reduced to a tuft of hairs called a pappus, in which, at first sight, it seems to be very difficult to recognise the calyx at all, until we find certain plants, where we can trace all gradations between the ordinary form of calyx and the pappus, as may be seen by examining *Gaillardia picta*, *Catananche cœrulea*, and *Scabiosa atro-purpurea*—the first and last of these plants presenting the two extremes, and the second-named one of the medium between the forms of calyx. Each "hair" of this tuft-like calyx or aigrette, as it is often called, may be either simple or plumose by the presence of secondary barblets along its side.

Mode of Insertion of Sepals.

—They are generally attached to the receptacle horizontally, leaving, when detached, a cicatrix shaped like the are of a circle or a horse-shoe. In the mode of insertion of the sepals there are, however, several minor modifications, though none are of any very great importance. An examination of the calyces of *Cytisus hypocistis*, *Pelargonium*, *Eri-ma violacea*, &c., will afford examples of several such.

Bacca, or Berry Proper.—This is a fruit with one or more loculements, generally many-seeded, indehiscent, pulpy. The attachment of the seeds to the placenta is lost at maturity, and they are scattered in the substance of the pulp. Ex. Gooseberry, and all the genus *Ribes*, *Vaccinium*, the fruit of the Vine. The term is applied rather vaguely, however. Thus, the fruit of the white Water Lily is called a berry; though the pericarp is membranous, and is surrounded by an enlargement of the receptacle, which becomes fleshy, and bears marks of its origin in the cicatrices which are on the outside of the pericarp, marking the places where the parts of the floral envelopes were attached before they fell. The bacca is also shown in the fruit of the Papaw, which may be classed under this head, as well as the somewhat peculiar fruit of the Duckweed.

In a future volume, we are promised "the history of the science, the description of the extinct species, the method of studying the science, and the laws regulating the distribution of plants over the world, according to the latest views." We shall look forward to its appearance with much interest.

* "A Manual of Botany, Anatomical and Physical." For the use of Students. By Robert Brown, M.A., Ph.D., F.L.S., F.R.G.S., &c. Edinburgh and London: William Blackwood & Sons. 1874.

COVENT GARDEN MARKET.

THERE is now being erected in Covent Garden Market a model of the way in which it is proposed to cover in the portion of the market that is exposed to the weather. It will be remembered that this is not the first recent attempt of the kind that has been made, a low and insignificant-looking section having been put up and pretty generally denounced not many months ago. The present attempt seems a more worthy one, being lofty and well-proportioned. So much interest being now manifested in these changes in Covent Garden, the moment is a fitting one for glancing at its past history and present condition.

Few who go to Covent Garden Market to buy fruits or flowers think that before the abolishment of conventual establishments by Henry VIII. the place where they are walking was occupied by the garden and burial-ground of a convent, although the name tells them that it was so. In the grand distribution of ecclesiastical spoils, Edward Seymour Duke of Somerset, brother-in-law of Henry VIII., and afterwards Protector of the Realm in the reign of Edward VI., obtained the land previously belonging to the Westminster monks as part of his share. In the year 1552, however, when he was beheaded, it reverted to the Crown, and "a patent [was] granted to John, Earl of Bedford, of the gifts of the Convent Garden, lying in the parish of St. Martin-in-the-Fields, near Charing Cross, with seven acres, called Long Acre, of the yearly value of £6 6s. 8d., parcel of the possessions of the late Duke of Somerset, to have to him and his heirs, reserving a tenure to the king's majesty in socage and not in capite" ("Privy Council Records," March, 1552.) The earl built himself a timber mansion in the same year on the site of Southampton Street, with a garden that ran down to the Strand, and an entrance from that thoroughfare, but the rest of the land he did not use. Covent Garden continued for some years to be an inclosure or pasture, extending westward from "the comune high waye that leadeth from the Stronde to St. Giles-in-the-Fyeldes" (now Drury Lane), almost to the present St. Martin's Lane. Queen Elizabeth's trusty Secretary of State, Sir William Cecil, lived in a house on the north side of the Strand, almost adjoining Bedford House, of the presence of which we are reminded by Burleigh and Exeter Streets, the titles of himself and of his son. This mansion was originally built upon the site of the parsonage-house of St. Martin's-in-the-Fields by Sir Thomas Palmer, in the reign of Edward VI. Adjoining his house Cecil had an orchard, and in September, 1570, Francis, Earl of Bedford, K.G., granted to him by a lease of twenty-one years a portion of the pasture of Covent Garden, which was next to his house, at a rent of 5s. a year. This lease is printed in the "Archæologia" (Vol. XXX., p. 497), from which we quote the description of the land:—"That the said Earle of Bedford, for the goodwyll he beareth to the said Sr. Willm. Cecyll, hath demysed, graunted, and to ferme letton, and by these presentes dothe demyse, grannte, and to ferme lett unto the said Sr. Willm. Cecyll, all that his porceyon or percell of grounde lyenge in the east ende, and being percell of the inclosure or pasture communely called Covent Garden, situate in Westm', which porceyon the said Sr. Willm. Cecyll doeth and of late yeares hath occupied at the sufferance of the said Earle, and hath bene and ys nowe dyvyded from the rest of the said inclosure called Covent Garden on the west syde of the said porceyon or p'cell nowe demysed wth certayne stulpes and rayles of wood, and is fenced wth a wall of muddle or earth on the east next unto the comune high waye that leadeth from Stronde to St. Giles-in-the-fyeldes, and on the west end towards the south is is fenced wth the orcharde wall of the said Sr. Willm. Cecyll, and on the south end wth a certayne fence wall of muddle or earthe, beinge therbye devyded from certayne gardens belonginge to the inne called the Whyte Heart and other tenementes situate in the high strete of Westm., comunly called the Stronde." The word "stulp" used in this lease is now obsolete, except in the county of Norfolk, and signifies a low post or boundary.

We hear no more of Covent Garden until about the year 1630, when another Earl of Bedford began to clear away the old buildings that were scattered over the ground, and to form the present square, by building from the designs of Inigo Jones, a church and piazza, in imitation of the square at Leghorn. In H. Lestrangle's "Annals of the Reign of Charles I." we find this adventure mentioned under the date 1632:—"The king having granted leave to the Earl of Bedford to edify at pleasure upon the Convent Garden, it being a very ample and spacious area and content, the earl plied his design with such celerity and quick despatch, as he soon reared such numerous rows of stately and ambitious buildings as made old London envy the magnificence of her sub-urbieary city." A new fashionable quarter had been much required, and the Earl of Bedford's houses were soon let to those members of the aristocracy who had no family mansions in London. In 1634 the earl granted a lease of two houses in the piazza to Sir Edmund Verney, Knight Marshal to Charles I., from which we learn that the colonnade was originally termed the

"Portico Walk," and, therefore, that the mistake of calling the arcades the piazzas was of later date. A covenant was made that the earl should have free "ingresse, egress, and regress, into, out of and from the sayd messuages, upon, by, over, and through the sayd Portico Walke, and that he, together with other his majesty's subjects, may at all times walke in, upon, and over the said Portico Walke, to and fro, at his and their own will and pleasure." Also, "that Sir Edmund Verney may expell, put, or drive away out of the said walke any youth or other person whatsoever, which shall eyther play or be in the said Portico Walke, in offence, or disturbance to the said Sir Edmund Verney." The annual rent was "one hundred and threescore poundes,"—a large sum in those days—which shows that the neighbourhood was in high repute. The inventory of fixtures is a very full and curious document of some interest in the history of building in England. It is printed in the "Archæologia" (Vol. XXX., p. 197), where it may be found. Hollar's view of Covent Garden was taken in the year 1647, and represents a very handsome square. It is taken from Russell Street, looking straight at the church, and shows the colonnade on the south-east side, which was destroyed by the fire in the last century. Through the colonnade we get a peep at the trees and garden-wall of Bedford House, on the south side of the square. The centre is enclosed by open posts, and the old gabled houses in Henrietta and King Streets are well shown up, adding greatly to the general picturesque effect.

The market originated in a few temporary stalls or sheds, which grew up under the shadow of the garden-wall of Bedford House. The squatters who held these stalls seem to have been recognised in 1656, as at that date the churchwardens of the parish made payment as follows:—"21 March, 1656. Paid to the painter for painting the benches and seates in the Market-place." Ten years later trees were planted "in the broad place;" and in 1668 money was collected from the inhabitants towards the expense of erecting a column in the centre of the square, which had been enclosed with railings 60 feet distance from the buildings. This column, with a dial on the top, was taken down in June, 1790. The various improvements made in the centre area are noticed in R. Brome's comedy, "The Weeding of Covent Garden," which was published in 1658:—

Of Covent Garden, when he wrote his book,
Some ten years since, when it was grown with weeds;
Not set as now it is with noble seeds,
Which makes the Garden glorious.

In 1671 the Earl of Bedford obtained a patent for his market, and eight years afterwards it was rated to the poor for the first time, when there were twenty-three salesmen, severally rated at 2s. and 1s. In 1701 Bedford House was pulled down, and the market, which had up to this date crouched beneath the shadow of its wall, was pushed into the centre of the square. Strype describes the look of the place about this time as follows:—"The south side of Covent Garden Square lieth open to Bedford Garden, where there is a small grotto of trees, most pleasant in the summer season; and on this side there is kept a market for fruits, herbs, roots, and flowers, every Tuesday, Thursday, and Saturday, which is grown to a considerable account, and well served with choice goods, which makes it much resorted unto." The market continued to prosper, and the sheds were gradually enlarged, and upper stories were added to them. This growth was watched with dislike by the vestry of the parish, who made complaints, but were disregarded.

In 1829 the sheds were all cleared away, and the site for the new market was prepared. The new building was erected in 1830, from the designs of Mr. Charles Fowler, at the expense of the Duke of Bedford. The market gained its great fame while it was excessively ugly, and the old sheds were as much frequented as the new building. The chief feature of the new market-house is the centre avenue, which became popular at once. Lately the holders of stalls have loudly complained of their unprotected condition, and the landlord has been asked to place a covering over them to prevent some of the inconveniences of our changeable climate. This demand is now under consideration. The present market, although, doubtless, a great improvement on the miserable sheds of the early part of the century, is much behind what a market of such fame, and the chief fruit, flower, and vegetable market, moreover of England, should be. Country towns have now handsome market-houses, and we might fairly look to the Duke of Bedford, who receives so large an income from Covent Garden Market, to make it worthy alike of its fame and of our great city.

When one reflects on the many fine markets now in existence, it is sad to think that the richest of all in products is also the ugliest and meanest of all; for there can be no question that the garden products sent to it are the most abundant and the best, on the whole, sent to any market. Yet, at present, it is, in attractiveness and conven-

ience, as far behind the Paris market as a small country theatre is behind the Covent Garden Opera-house. There is no space on which the various fruits and vegetables can be seen or sold to advantage; on market mornings the crowd is so dense that business is much retarded; while, as for the public visiting the market on those occasions, it is out of the question. Room for storage there is little or none, so that unsold articles have frequently to be taken away from the market at a great loss to their owners. Few who know the extent and quality of the garden produce of the environs of London will deny that a market designed so as to afford proper convenience for the display of this produce would form the most interesting spot in London. It would be beautiful, too, as the various flowers, fruits, and vegetables changed week by week with the seasons. But it is not from the point of view of ornament only that the matter is important. The public see little of the misery and danger which result from having such a busy crowd in the market exposed to the inclemency of the weather at all seasons. Before our office windows, and in the various streets and open parts of the market, hundreds of men and waggons of vegetables stand on many dreary mornings, till both are as saturated as if they had gone under the falls of Niagara without the customary overcoats; such is the present state of things. Let us hope we may yet be able to give a more cheerful report.

GARDENING FOR THE WEEK, AND AMATEUR'S CALENDAR.

The Flower Garden and Pleasure Grounds.

ALL deficiencies in beds or borders will, by this time, have been made good, and it is now necessary to endeavour, by every possible means, to keep the plants in a growing and healthy condition for as long a period as possible. Training, staking, tying, and pegging down must receive close attention; and, if the weather continues dry, both beds and borders must be liberally supplied with water. The plants should also be strictly confined to the spaces allotted to them, so that the outlines of beds and clumps may be clearly defined. Stake and tie up Hollyhocks, Dahlias, and other tall-growing herbaceous plants which may be growing on the margins of shrubby borders, and let large clumps of Narcissi and other bulbous plants be overhauled where the leaves show symptoms of decay and the bulbs have, consequently, become ripe. Such bulbs as Narcissi, Crocuses, Scillas, Tulips, &c., may be stored away for the present, to be planted at any convenient time during the autumn; but a lengthened exposure to air tends to impair the vigour of such scaly bulbs as those of the Lily family; therefore, the shorter time they are kept out of the soil the better, and any clumps of them that have been taken up for the purpose of separation or division may be planted again at once; and, in order, as far as possible, to prevent any accidental injury being done to them while at rest, they should be carefully labelled at the time of planting. Remove dead and decaying blooms from Roses and other flowering shrubs; remove also seed-pods from Rhododendrons, Azaleas, and other American plants as soon as they have done flowering, as this, if carefully attended to now, will have a beneficial effect upon the bloom of the following season. When this is done a liberal watering should be given to the plants, an operation which should be occasionally repeated according to the state of the weather. Cuttings may now be made of the young wood of Roses; they will root freely under hand-glasses, as will also cuttings of Pinks and Pansies, *Diolytra spectabilis*, and various other hardy herbaceous plants, such as Sweet Williams and the different kinds of double Wallflowers.—P. GRIEVE, *Culford Gardens, Bury St. Edmund's*.

Indoor Plant Department.

Poinsettias should now be shaken out, re-potted, and encouraged to make strong sturdy growth. Another useful winter-blooming plant is *Begonia dipetala*. If small plants of this are at hand, and grown on freely, they will furnish quantities of bloom in the winter. Allamandas, *Clerodendron splendens*, and *Dipladenias*, showing flower freely, should now be trained round their trellises, but not too closely, as that gives them too stiff an appearance, and also has a tendency to cause premature decay in the leaves, which, if allowed to overlap each other, turn yellow and decay; this has also a tendency to weaken the plants and to reduce their blooming capabilities. Expose them to all the light possible, using just sufficient shading material to break the direct rays of the sun; by this means the flowers will be produced much stouter, and will stand in a cut state, if required, much longer than when treated more tenderly. Autumn-struck cuttings of hard-wooded stove plants, such as *Ixorias*, *Allamandas*, *Gardenias*, &c., which have been potted during the winter,

will, by this time, require a further shift. The aim of the cultivator ought to be to get the plants up to the required size as quickly as possible; if such things are allowed to become stunted through being pot-bound, it takes a long time afterwards to get them to move; in fact, it is better to commence with a cutting than to grow a plant on that has been allowed to get into such a condition. It would seem that the increased demand for cut flowers at the present day is illimitable; it therefore behoves gardeners to make provision to meet it. In most establishments, large or small, there will be some things held in greater esteem than others. Therefore, it is impossible to name any plants in particular that would be held in general estimation. Yet, during this and the next two months, flowers from stove plants will be largely used for mixing with Roses and other out-door productions. There is a great charm in variety; yet the old system of growing collections of plants where the object was to include the greatest number possible, both of species and varieties, is anything but calculated to meet the requirements of the present day; it is much better to continue to a reasonable extent the number of varieties of plants grown to such as are the most attractive, last the longest, and are held in the greatest estimation. If there is one plant more than another that is more generally useful as a decorative, stove, or intermediate house plant, and capable of producing quantities of cut flowers for eight or ten months in the year, it is *Ixora coccinea*. Now is a good time to either strike cuttings or procure plants of it; and, if kept clear from insects, and grown under the same conditions as to temperature and atmospheric moisture, summer and winter, that will suit Cucumbers, it will amply repay for the trouble bestowed upon it. Its flowers will stand in water for a week, and it can be cut with impunity without injuring the plants. In conservatories every attention should be paid to keeping foliage clear of insects, and to the encouragement of its healthy development. The *Clinanthus panicus* is a plant very liable to attacks of red spider, and must, therefore, be closely watched and often syringed. Plants in pots are more likely to suffer from drought at this season than those in borders, and must, therefore, be frequently examined. Tree Ferns, some Palms, and a few quick-growing large plants in borders, should have basins of earth formed round their bases, so that a thorough soaking of water can be given to them at one time without running over the border. Fuchsias, both in the form of climbers and pyramids, are now about their best. Pinch their side-shoots in freely until a few weeks prior to allowing them to bloom, and give a little liquid manure about twice a week. In growing the double-flowering kinds of Pelargonium, endeavour to induce a stubby growth; and, after their flowers are fairly set, assist a freer development by means of manure-water. Show Pelargoniums that have done blooming should be set outside, so as to enable them to ripen their wood, and they should be allowed to dry off gradually. Lilies belonging to the Japanese section should now be coming beautifully into bloom, and should be liberally supplied with stimulants. When re-potted, the pots should only be filled to within two inches or so of the top, so as to leave room for top-dressings of good rich compost. Before cutting the blooms of these Lilies, the anthers should be carefully removed, so as not to spoil the petals by the diffusion of the pollen. Erythras coming into bloom should be assisted by means of manure-water. Statice should be re-potted as they require that attention, but in the case of old plants, top-dressings and manure-waterings should be resorted to instead of giving them a shift.

Orchids.

Orchids recently imported, and which have been laid on a bed of Moss until the young growth has made its appearance, may now be potted in a fresh open compost consisting of fibrous peat and Sphagnum, on a well-drained bottom. I have always found it best in practice to watch the plants carefully until the young growth has made its appearance in the form of a plump bud, or swelling at the base of the old pseudo-bulbs, and then to pot them at once before the cluster of young roots was emitted. The roots then find their way into the compost without injury, while it is almost impossible to re-pot plants with the young rootlets an inch or more in length without bruising off their delicate green tips; and, when that happens, the young growth is very considerably checked. This is specially true in the case of Cattleyas, *Odonoglots*, and *Laelias*, and often results in their making a second abnormal growth, which, in its turn, is but half developed, and the consequence is few or no flowers. Keep a careful look out for insect pests. In the cool houses little shell-snails (*Helix alliaria*) often abound in the Sphagnum in large quantities, and these must be diligently picked off by hand and destroyed. Slugs often eat the succulent young growth of *Odonoglots*, *Disas*, and *Masdevallias*, and must be treated in the same manner. Woodlice, which often abound and eat leaves and roots, should be driven from their day-light haunts among the crocks or compost by plunging the plants gently into a pail of water, and removing them

one by one as they crawl out. Another excellent plan is to lay slices of Potatoes on the tops of the pots, and to examine these every morning. Another source of annoyance to the Orchid grower is the presence of ants, which often take up their quarters in Orchid-houses in considerable numbers, and overrun everything. The harm which they do does not consist in eating the plants, but in carrying rubbish into the axils of the leaves. The best way to destroy ants is to lay pieces of sponge soaked in treacle, and squeezed nearly dry in their runs. They enter the pores of the sponge in quest of the sweets, and are made prisoners in immense numbers, when they may readily be destroyed by collecting the sponges and dipping them in boiling water. Plants making growth, such as *Cælogynes*, *Oncidiums*, *Odontogloss*, and *Cattleyas* should have a copious supply of moisture at the root, and a genial atmosphere must be maintained. *Dendrobies*, which have finished their growth, may be placed in a dry airy house, and allowed more sunlight than they have lately been having.—F. W. BURRIDGE.

Indoor Fruit Department.

In early Pineries, in which the fruit has been cut, the plunging or fermenting material should be turned out, and the pits thoroughly cleansed and lime-washed. Snickers should be firmly potted in six-inch pots, using for them fibry loam and a little charcoal; after being potted they should either be plunged in front of late succession plants or in separate beds, and shaded for a short time during bright sunshine. Vines swelling fruit should be allowed abundance of moisture, both at the root and in the atmosphere. Late Vine-borders should receive good soakings of manure-water, either from the farmyard or the cesspool, occasionally; immediately after the manure-water has been applied, another soaking of pure water should be given, in order to dilute the first application, and to wash it down. Figs are now producing a second crop, and in most instances this crop seems unexceptionally fine. They should be allowed abundance of moisture at the root, overhead, and in the atmosphere. Stimulants are not often applied to Figs in the way of manure-water, but they thoroughly enjoy a mulching of good fibry loam and rotten manure. Peach and Nectarine trees done fruiting should be well syringed and supplied with water; they should also be freely exposed to the air. Melons done fruiting should either be thrown away and replaced by young ones, or cut back and encouraged to start afresh; but young plants are best.

Hardy Fruits.

The greater portion of wall-fruits will now be about commencing their second swelling. Stoning will be nearly perfected, and with it the risk of more fruit dropping. It is always safe practice to defer the final thinning till this uncertain process is completed. Some refuse to thin at all until the fruits are stoned. This is to invite failure; for, probably, the greatest strain on the tree is furnishing stone and forming stone perfecting matter. It is always safe practice to leave one-half or one-third more fruit to stone than it would be either prudent or profitable to allow the tree to ripen. In thinning fruits of Peaches, Apricots, Nectarines, and Plums, attend to such trifles as the proximity of branches, nails, and other fruits, and see that each fruit has freedom to develop itself without being crushed or malformed in any way. It is often needful to unmail or untie a branch, and to partly twist it round to place the fruit on it in the most favourable position for developing its full size. Of course, when the crop is irregular, we are glad to leave all we can. But stone fruit, crowded together in clusters is simply superior fruit ruined, unless it be Apricots or Plums for preserving. But, in good seasons, and with all superior fruits, more depends on such small matters than on any great thing that we can do for the trees. Another trifle is the different modes of fruit-bearing of different fruit trees. Peaches and Nectarines, Morella Cherries, and some Plums, for instance, fruit best, and the trees are best preserved in a fertile state, and most successfully furnished with wood, by reserving only the young wood of the previous year's growth for fruit-bearing. Hence, in dis-budding or summer pruning such trees, the superfluous shoots are taken clean away, not a morsel of the shoot is left. Apricots, most Cherries, and many Plums, on the contrary, bear fruit more on spurs than on the young wood; these spurs are produced by Nature, and can also be manufactured by art, the most common mode of artificial production being the leaving of two or three buds at the base of each shoot, pinched back or pruned off. The sap that was previously expended on a growing shoot is now diverted into the development of a fruit spur. Such spurs, however, would be a positive nuisance in the first set of trees named; they are essential to the full fertility of the second, and of Apples, Pears, Grape Vines, &c.; and yet the entire difference of treatment and result turns upon a natural peculiarity of the trees overlooked by many, and, perhaps, hardly assessed at its proper value by anyone.—D. T. FISH.

Kitchen Garden.

Although a few slight showers have fallen during the past week, which, for the time, had a beneficial influence upon vegetation, the rainfall, in this district at least, has not been sufficient to reach the roots of plants; it will, therefore, still be necessary to persevere in the use of every expedient that can be adopted for the mitigation of drought. Peas, Cauliflowers, and Lettuce, can only be kept in good growing condition by careful attention. Bring up all arrears in planting such things as Broccoli, Savoys, and Winter Greens of all kinds. Plant also a few Cabbages for autumn use somewhat thickly together. It is better to push forward work of this kind now, than to wait for a more copious fall of rain, as one or two good waterings will establish them in their new quarters, and when rain comes, they will be ready to start into active growth at once; there will, moreover, be no occasion to tread the ground when it is wet. Celery for late spring use should now be thought about. The following is a good plan for securing and keeping spring Celery in good condition. About the first week in July, after the early Peas are cleared away, a trench is opened along the front of a south border near the water supply, about 1 foot wide and 8 inches deep; 6 inches in depth of rotten manure is then placed all over the bottom, and well forked over; sufficient soil is returned to the trench to raise it up nearly, but not quite, to its original level. Plants of Williams's Matchless, or some other good red kind of Celery, raised from seeds sown in April thinly, or thinned out afterwards in the open air, are selected and planted out all over the bed, 6 inches apart. Water is given almost daily in dry weather, in the evening; and about the end of November, or just before severe frost is apprehended, each plant is tied up with a bit of matting; and the blanching process is effected in one operation, by heaping up to the requisite height, round and amongst the plants, burnt earth or ashes. Where slugs are troublesome, this will keep them off, and the Celery will be sweet, crisp, and free from decay. During sharp frosty weather, I cover with clean dry straw or Fern. In March the Celery may be dug up and laid in close together, in the same material, under a north wall; and, thus circumstanced, it will keep good long after that treated in the ordinary way has either decayed or "bolted." About the 8th or 9th, sow Enfield Market and Atkin's Matchless Cabbages for early spring use; and possibly some of them may turn in, in February or March. A further sowing of these and other kinds may be made about the 18th, and again (to stand all winter in the seed-bed) about the end of the month. If the weather continues dry, soak the land with water thoroughly several hours before sowing, and afterwards shade. Sow also a little Prickly Spinach and Tripoli Onion seed for early autumn use, but the main sowings of these things should be delayed till the end of the month. Make frequent sowings of Lettuce, Endive, Radishes, &c., at this season, to ensure a good supply, as a good crisp salad is especially important in hot weather. Parsley may yet be sown for winter and spring use, as also Early Horn Carrots, where young Carrots are in demand. Make a final planting for the season of Dwarf French Beans, selecting an early kind for this purpose. Mulch the ground between Vegetable Marrows, and peg out the shoots; thin out, stop, and nail up Tomatoes, and mulch them with manure. Shallots and Garlic, as soon as the growth dies down, should be taken up and spread out in the sun to dry, turning them over occasionally. Cucumber in pits and frames should be frequently top-dressed, and well supplied with water, shutting them up early in the afternoon.—E. HOBAY.

The Siphonic Watering-pot.—We have received from the patentees, Messrs. Alfred Smith & Co., of Bath, one of these newly-invented watering-pots, the special advantages claimed for which are as follow:—1. A steady and uniform flow of water, which may be regulated at pleasure. 2. Its adaptability for watering plants on upper shelves, as the pot can be used without being tilted or inclined. 3. By simply pressing a spring above the handle, it may be used under hand; or, by pulling a similar contrivance under the pot, plants may be watered at a higher elevation than can conveniently be reached by any one using an ordinary watering-pot; thus obviating, in many cases, the use of steps. Gardeners who have used this pot speak well of its action; and, doubtless, for self-watering, it is greatly superior to any ordinary watering-pot.

New Manure.—M.M. Bellinet and Martinet state that they have succeeded in converting the nitrogen of the air into ammonia without expense, without chemical manipulation, and even without human intervention at all, by the use of certain bituminous schists. These schists contain, in much larger proportions than farmyard manure, all the elements necessary for the growth of plants. Sulphide of carbon is produced at the same time, and is said to be the only remedy for the phylloxera or Vine disease.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY'S
ROSE SHOW.

JULY 1ST.

Owing to late fluctuations in temperature and heavy rains the show of Roses on this occasion was not equal to that of former years. Several growers who had entered the list as competitors failed to put in an appearance. Mr. P. Barr and Mr. G. F. Wilson contributed much to the interest of the show, by staging two fine collections of cut Lilies; and some splendid examples of Iris Kämpferi were shown by Messrs. E. G. Henderson. In class 1, for seventy-two distinct varieties, Mr. G. Prince, 11, Market Street, Oxford, was first with fine blooms, considering the season. Among light-coloured varieties, we noted *Thérèse Levet*, a flower of soft satiny rose; *Marguerite de St. Amand*, silvery rose, fine incurved flower; *Belle Lyonnaise*, a pale sulphur tea-scented variety; *Elie Morel*, a fine flower, bright rose margined with lilac; *La France*, one of the finest of all new Roses, and of a bright rose, the outer petals being nearly white; *Baronne Rothschild*, is a fine open flower of considerable merit, the colour being a soft rose-salmon; *Mons. Purodo* is also a nice clear sulphur-tinted variety, belonging to the Tea-scented section. The dark flowers shown in this group were very fine, and included among other kinds is the following, viz., *Maurice Bernardin*, a fine open flower with large smooth petals of a bright crimson colour; *Alfred Colomb*, a full Rose, of the same colour as the last; *Claude Levet*, a fine incurved bloom, of a dark crimson tint. The second prize was awarded to Mr. C. Turner, of Slough, who had evenly matched flowers very tastefully set up. Among light kinds were *Paul Nerou*, a fine large rosy-lilac; *Abel Grand*, light rose; *Princess Mary* of Cambridge, soft flesh; *President*, light rosy-salmon; *Henri Pajes*, a fine full flower, of a pale rosy-lilac colour; *Gloire de Dijon*, *Victor Verdier*, and others equally good. Among dark varieties, were fine blooms of *Camille Bernardin*, crimson-purple; *Sonateur Vaisse*; *Madame Victor Verdier*, rich crimson; *Dupuy Jamin*, a fine, smooth petalled flower, of rich lilac-purple; *Ferdinand de Lesseps*, velvety crimson; *Dr. Andry*, and *Lady Suifield*. Messrs. G. Paul & Sons, of the Old Nurseries, Cheshunt, were third, with a very fine collection, in which a new unnamed seedling Hybrid Perpetual was conspicuous, the colour being a rich fiery crimson; there were also fine blooms of *Alfred Colomb*, a soft crimson-purple; *Camille Bernardin*; *La Fontaine*, a soft lilac-purple; *Nardy Frères*, a dull purple; *Victor Verdier*, and other equally well-known kinds. In class 2, for forty-eight blooms, three trusses, Mr. Chas. Turner was first with fine flowers, the most conspicuous being three fresh blooms of *Ferdinand de Lesseps*, rich crimson; *Abel Grand*, also fine; *La France*; and *Baronne Rothschild*, both excellent light flowers; *Duke of Edinburgh*; *Prince Camille de Rohan*; and *Caas Lefebvre*, very fine dark varieties. In Messrs. Paul & Son's collection, which was second, were fine blooms of *Marchal Niel* and *Belle Lyonnaise*, both yellow Teas. Mr. Cranston, King's Acre, Hereford, was first in the class for twenty-four varieties, three trusses of each. Among dark kinds we noticed *Marie Baumann*, *Beauty of Waltham*, *General Jacquemont*, and *Duke of Edinburgh*; also *Paul Verdier*, a bright rosy-crimson. Among light varieties, *Madame Eugénie Verdier*, *Abel Grand*, *Baronne Rothschild*, *La France*, *Bessie Johnson*, and *Elie Morel*, were good. Mr. J. Fraser, of Leyton, was second with nice trusses, well set off by buds and foliage. Among the different varieties we notice *Sonateur Vaisse*, *Duke of Edinburgh*, *Dr. Anry*, and *General Jacquemont*, all excellent fiery-crimsons, the light flowers being well-represented by *Madame E. Verdier*, *Elie Morel*, *La France*, and *Baronne Rothschild*. Mr. G. Prince, 11, Market Street, Oxford, was third with nice flowers. The blooms of *Marie Baumann*, in this group, deserve more than a passing notice, and show what a splendid flower this is when well grown. The best box of twenty-four Roses in the show came from Mr. J. Cranston, who had *Jean Chepin*, a rich crimson-purple, but rather too small for show purposes. *Maurice Bernardin*, *John Hopper*, *Marchal Vaillant*, *Marchal Niel*, and other old favourites. Mr. C. Turner, of Slough, was second; and Mr. E. Cooling, of Bath, was a very excellent third.

In the Amateur's Classes, the Rev. C. Arkwright, Pencombe Rectory, Hereford, was first with forty-eight varieties, some of which were very fine. The second award in this class went to the Rev. J. M. B. Camm Monkton Wyld, Dorset, who had nice stands in which Tea-scented varieties were very fine. Mr. W. Farren, 10, Crescent, Cambridge, was third; and Mr. W. Ingle, gardener to Mrs. Russell, Colchester, was a good fourth, the blooms being very neatly set up. Mr. J. W. Chard also staged a nice collection of blooms in this class. In class 6 (twenty-four Roses) Mr. W. Farren was first with a very effective group. Second, F. H. Gould, Esq., Mortimer Vicarage, Reading, with fine flowers rather soiled by the recent wet weather. Mr. W. Ingle third. Several other collections were staged in this class. In class 7 (twelve distinct varieties), Mr. J. Marp, Corn Market Street, Oxford, was first with fine fresh flowers, including *Madile*, *Marguerite Dombain*, a fine full satiny flower of the softest rose; *Paul Verdier*, Countess of Oxford, and others. Thirteen good stands were staged in this class.

In class 8, the prizes in which were offered for Roses sent out during the past three years, the first went to Mr. Cranston, who had *Annie Laxton* a fine deep rosy

flower of good form; *Cheshunt Hybrid*, a nice variety, but past its best; *Mons. Etienne Levet*, a fine fully expanded flower of a soft rosy-lilac tint, and with very smooth petals; *Reynolds Hole*, a deep velvety-crimson, and others. Mr. Charles Turner was second with *Miss A. Hassard*, a finely formed full flower of the most delicate rosy flesh; *Bessie Johnson*, delicate flesh; *Princess Christian*, a globular full flower of a pale satiny rose; *Annie Laxton*, President Thiers, John Stuart Mill, a fine deep rosy-purple, and others. Third, Messrs. Paul & Son, who had nice flowers of *Wilson Saunders*, a deep velvety crimson; *Etienne Levet*; *Lyonnaise*; *Francis Michelson*, soft rose; *The Shah*, deep crimson; *Cheshunt Hybrid*, *Hyppolite Jamin*, *Thomas Miles*, a full deep rosy-crimson flower, and others. Class 9, six trusses of any new Rose sent out during the last three years.—First, Mr. C. Turner, with *Etienne Levet*, a finely-formed full flower of a deep rosy-lilac colour. Messrs. Paul & Sons were second with *Annie Laxton*, and a duplicate set consisted of *W. Wilson Saunders*. Mr. G. Prince was third with *Elie Morel*, a fine rosy flower, the petals being beautifully crisped.

Class 10, for Twelve Tea-scented Roses.—First, Messrs. Paul and Son with *Catherine Mermet* a delicate salmon-tinted flower; *Marchal Niel*, *Niphetos*, a fine variety with paper-white flower; *Gloire de Bordeaux*, a bright rosy-lilac; *Cheshunt Hybrid*, *Souvenir d'un Ami*, soft flesh; *President*, white suffused with flesh, and others. In the Amateur's Class, the Rev. G. Arkwright was first with very fresh flowers, including *Devonensis*; *Compte de Paris*, flesh; *Catherine Mermet*; *Souvenir d'un Ami*; *Reubens*, creamy-white; *Triomphe de Rennes*, an old favourite of a delicate sulphur tint; *Souvenir d'Elise*, a finely formed bud, creamy-white; *Gloire de Dijon*, and other well-known kinds. Mr. W. Ingle and Mr. W. Farren had nice groups, and were second and third respectively. In the last-named collection we noted *Marie Sisley*, a deep rosy flower with peculiarly pointed segments. The Rev. J. B. M. Camm was first for twelve trusses of *Alfred Colomb*, a fine purplish-crimson flower; and Mr. J. W. Chard was second. Messrs. Paul & Son were first for twelve trusses of *Duke of Edinburgh*, and their stand of this fiery crimson-tinted variety was much admired; the second award went to Mr. C. Turner. For the prize offered for twelve trusses of *Baronne Rothschild*, eight fine collections were exhibited. The Rev. J. B. M. Camm was first with fine flowers, well coloured. In the nurserymen's class, Mr. C. Turner took corresponding honours with an equally fine group of blooms. The best twelve trusses of *La France* came from the Rev. G. Arkwright, whose flowers were large and finely coloured. The Rev. J. B. M. Camm and Mr. Prince also showed fine stands in the same class. Mr. G. Prince was first with twelve flowers of *Marie Baumann*, one of the best Roses in its class. Two fine stands of Tea Roses, consisting of *Gloire de Dijon* and *Souvenir d'un Ami* respectively, came from the Rev. G. Arkwright. Groups of Roses in pots came from Messrs. G. Paul & Sons and Messrs. C. Turner, the prizes being awarded in the order in which the names stand.

As regards miscellaneous subjects, a silver medal was awarded to a fine collection of decorative stove and greenhouse plants, Orchids, and Ferns, which came from Mr. B. S. Williams. Among them was a nice plant of the rare *Aerides Schroderi*, bearing a spike of large richly tinted flowers; *Disa grandiflora*, and a good variety of *Oncidium cucullatum*. Mr. J. Aldous also had a group of decorative plants, to which a small bronze medal was awarded. A small bronze medal was likewise given to some splendid cut blooms of *Pinks* and *Verbenas* from Mr. C. Turner. Messrs. E. G. Henderson & Son sent some dwarf *Lobelia* in pots, very profusely bloomed. Among them *L. Nemesis* was a fine clear blue, about 3 or 4 inches high; *L. Aspasia*, same habit, but rather deeper in tone; *L. pumila maxima*, a great improvement on *L. pumila*; *L. Unique*, a dense variety of the most vivid blue imaginable, and one which will prove invaluable for the now popular system of carpet bedding. A fine group of single and semi-double flowered Larkspurs also came from the same firm, together with a collection of tri-color zonal Pelargoniums. Mr. Harrison Wear sent cut spikes of a yellow-flowered Foxglove (*Digitalis lutea ochroleuca*), the throat of which was mottled with dark brown. Mr. R. Dean sent a very showy collection of cut spikes of *Antirrhinums*. Messrs. Carter & Co. had a new Hybrid *Scabanthus*, named *Butterfly*, the segments of which were white, spotted with a dark purple, also a deep rosy variety of *Helysarum coronarium*. Mr. G. F. Wilson furnished a choice collection of cut Lilies, and two splendid pans of *Nertera depressa*, very fresh and dense, profusely sprinkled with coral-tinted berries of the size of small Pens. It is quite hardy in a shady situation, and is found widely distributed in mountainous districts of both hemispheres. Messrs. Dixon & Co., of Hackney, sent lifted plants of *Calceolaria Golden Bell*, a kind which bears large golden flowers. Messrs. Barr & Sugden had a splendid group of cut Lilies of the *Thunbergianum* and *Martagon* types. Messrs. J. Backhouse, of York, sent a blooming plant of *Mormodes Pardia*, a native of Mexico, having spindle-shaped bulbs nearly a foot long, bright green-ribbed foliage, and a short spike of yellow flowers, profusely speckled with dark brown; also plants of *Oncidium stelligerum*, a native of Mexico, closely resembling the rare *O. Barkeri* (*O. biguttatum*) in habit, but with longer and flatter pseudo-bulbs. The flowers are about an inch and a half across, borne on arching branched spikes 5 or 6 feet in length. The sepals and petals are of a creamy-yellow, spotted with brown, the lip being three-lobed, lateral lobes white, and central lobe purplish-brown. Messrs. Dick Radclyffe & Co., of

High Holborn, and Messrs. J. Bromwich & Co., South Belgrave, exhibited some elegant Fern-cases, very tastefully arranged.

Fruit.—The show of fruit was limited to one or two Melons of average merit, and a fine collection of Cherries consisting of a dozen dishes sent by Mr. J. Woodbridge, gardener to the Duke of Northumberland, at Syon. Mr. McLaren, of Ash, Surrey, sent cut fruiting branches of a prolific Raspberry, named *McLaren's Prolific*; the fruit is large of a dark red colour, but deficient in flavour. A new seedling Grape, named the *Duchess of Edinburgh*, came from Mr. W. Melville, gardener to George Gibbs, Esq., The Royal Vineyard, St. Lawrence, Jersey; the bunches were long and tapering, the berries large and oval, green in tint, fine and distinctly netted with yellow, like some of the smooth skinned Gooseberries, the foot-stalks were thin and slightly warted; though sweet and juicy with a slight Muscat flavour, it was thick skinned and otherwise of little merit. Mr. Perkins, gardener to Charles Keyser, Esq., sent a pair of fine Queen Pines, the produce of rooted suckers planted in August 1873; the heavier of the two was a splendid fruit, symmetrical and well swelled, weighing 5 lbs. 13 oz.; the smaller one being only 7 oz. lighter.

Vegetables.—Considerable interest was occasioned among practical gardeners and amateurs by the fine collections of Peas sent in competition for the prizes offered by Messrs. Carter & Co. The first award went to Mr. W. G. Fragnall, gardener to G. D. W. Digby, Esq., Dorset. The varieties were *Champion of England*, pods rather small but remarkably well-filled; G. F. Wilson, pods well-filled and the Peas of good flavour. Superlative, with very large-curved and curiously-pointed pods, the Peas in which were rather small; *Hundredfold*, with well-filled pods; Wonderful, one of the best of the group, the pods being rather small but well-filled, and the Peas large and of fine flavour; *James's Marrow*, a prolific variety with well-filled pods of medium size. Mr. H. Elliot, gardener to J. Hibbert, Esq., Maidentail, was second with *Laxton's Quality*, evidently a fine and prolific variety, the flavour being sweet and good; *First Crop Blue*, another good cropper of excellent flavour; *Laxton's Supreme*, in the way of Superlative but rather smaller; *James's Marrow*, Fortyfold, a productive variety of good flavour; and G. F. Wilson. The first prize for four varieties went to Mr. F. Baily, gardener to T. T. Drake, Esq., Shardeloes. These were *Superlative*, *Laxton's William the First*, *Laxton's No. 1*, a small pointed kind but prolific, and *Laxton's Filibasket*. Mr. G. T. Miles was second, and Mr. R. Gilbert, of Burghley, third. Mr. R. Dean sent harbin of two new Peas from his grounds at Geddton. One was named *Robert Penn*, a prolific cropper, with from seven to nine Peas in a pod. The other was called *Dean's Dwarf Marrow*, smaller, but very productive.

First-Class Certificates were awarded to the following novelties:—

Rose Sir Garnet Wolseley (Cranston).—A seedling from *Camille de Rohan*, and in colour similar to *Marie Baumann*. It is a nice incurved flower of a rich fiery-crimson colour.

Iris Kämpferi (E. G. Henderson).—A fine flower, having six broad imbricating petaloid segments of a rich clear colour, with a bright golden streak at the base. The foliage resembles that of some *Glaucolus*, and the three-flowered scape is fully a yard high. It is one of the best of a beautiful, but shy-flowering, section of this genus.

Tricolor Pelargonium Dr. Masters (Henderson).—A dwarf, dense habit variety of considerable merit. The leaves, which are crumpled, are green in the centre, bordered with clear yellow, and having a broad bronzy scarlet zone.

Silene pendula l. pl. (Dean).—This is a very pretty double-flowered "Catch-fly," of the brightest rose colour. It will prove useful for bedding purposes and dry sunny banks.

Lobelia (pumila) magnifica (Bester).—This is the best dwarf *Lobelia* we have ever seen, and is certain to become popular. A little patch about 3 inches high and as much through bears about 200 flowers of the most vivid blue imaginable.

Echeveria Peacock (Croucher).—A robust habit species, the thick bluish glaucous foliage being very symmetrically arranged; each leaf is concave above, with their points incurved. It is one of the best of the small growing section, and is effective as a pot plant. The flowers are of the usual form and deep orange colour, borne on a simple second spike from 12 to 15 inches high. The spike is of a reddish-purple colour, clothed with lance-shaped bracts of the same colour as the leaves.

WEST HAM HORTICULTURAL SOCIETY.

JUNE 30TH.

This suburban exhibition was quite a success, the stove and greenhouse plants being excellent—indeed, better than those staged at some of our large shows this year. The principal exhibitors among nurserymen were Messrs. B. S. Williams, Robinson, and Wright; and Mr. J. Ward, Mr. D. Donalt, Mr. J. Douglas, and Mr. J. Wheeler among amateurs. Fruit, though sparsely represented, was excellent in quality; Grapes, Strawberries, and Cherries being especially fine. Vegetables, though somewhat scarce, were of average merit. The New Park, in which the exhibition was held, is of considerable extent, and contains some fine specimen Yews, Poplars, and some fine old Malberry trees, in the trunk of one of which an Elder bush has established itself, and

is gradually splitting the Mulberry as it increases in size.

Stove and Greenhouse Plants.—In the nurseryman's class for twelve specimens, Mr. E. S. Williams was first with a well-grown group, in which were *Erica abdita*, bearing large indented wax-like flowers of pearly whiteness; *E. laevindshii*, a well-known yellow flowered variety; *Alchemilla Hendersonii*, and *A. cathartica*, *Anthurium Shoenzerianum*, *Bougainvillea glabra*, and other equally well-managed plants. In the amateur's class, Mr. J. Ward, gardener to P. G. Wilkins, Esq., of Leyton, was deservedly first, with twelve splendid plants, among which the following deserve special mention, viz., *Anthurium Schoenzerianum*, with about twenty brilliantly coloured spathes; *Stature profusa*, a perfect mass of bright blue flowers; *Kalanthes*, *Frederick Deckeri*, rich scarlet; and a splendidly coloured *Bougainvillea glabra*. Mr. J. Wheeler was second with a well-grown group, in which was *Stephanotis floribunda*, a perfectly globular mass of fresh leathery foliage of the darkest and most healthy green tint, interspersed with great clusters of sweet-scented snowy flowers. This was supported by an excellent specimen of *Bougainvillea glabra*. Mr. D. Donald was third with *Erica Abundantia*, a fine old white variety with long tubular flowers; *Yucca ambigua*, well bloomed; *Diplazium amabilis*, and others. Good collections of fine-foliated plants were furnished in excellent condition by Mr. D. Donald, Mr. J. Ward, and Mr. J. Douglas, the prizes being awarded in the order in which the names stand. In looking over these groups we noted a splendid specimen of the sombre-tinted *Cycas circinalis*, with graceful pinnate foliage, 5 or more feet in length. This plant is as elegant as a Palm, and, like its congener, *C. revoluta*, stands a good deal of rough usage; hence, as a companion to the latter, it deserves generally to be more grown for all kinds of modern decoration and for sub-tropical gardening during the summer months than it is. Mr. Ward's plants, although rather small, were superior to any others in the tent; they consisted of good examples of *Sarracenia flava*, *Coccyz Weddelliana*, a remarkably fresh and promising little Palm; *Croton undulatum*, one of the most effective of all the newer kinds; *Lantana rubra* and *Areca luteo-venis*, both distinct and effective decorative Palms; *Dracaena lineata*, *Yucca aloifolia variegata* and *Dicksonia antartica*, a well-known Tree Fern that luxuriates in a cool temperature. In the Amateur's Class for six stove and greenhouse plants, Mr. Ward was again first with a young fresh *Erica Williamsii*, the flowers of which are of a bright orange tint, borne in numerous trusses backed by handsome leathery foliage. The group also contained good plants of *Erica depressa*; *Phlox paniculata* *Barnesii*; a well-grown *Kalanthes coccinea*, about 3 feet by 2, and other plants equally effective. In the Nurseryman's Class, for a group of decorative plants not exceeding twenty-four in number, arranged for effect, Mr. B. S. Williams was first with a splendid collection of choice plants, all being of a more or less choice character, and comprising flowering and foliage plants, Orchids, Palms and Ferns. To Messrs. Rollison of Tooting, who also had a splendid group, the second prize was awarded; and Messrs. Wright of the Nurseries, Lee, Kent, were third. Heaths were unusually excellent, the best eight being contributed by Mr. Ward, who had splendid specimens of *E. NePlus Ultra*, a fine fine-habited variety with bold white flowers; *E. formicaria* major, a deep rosy-flowered kind, profusely bloomed; *E. formicaria* rosea, nicely coloured; and *E. graminifera*, a rich orange-flowered variety, tipped with green. In the class for four specimens, Mr. Ward was first with *E. ampullacea Williamsii*, a fine long-flowered white kind; *E. tricolor* rosea, well-coloured, and others.

Orchids.—Of these Mr. Ward's collection contained fine richly-coloured varieties of *Odontoglossum Alexandrie*, *Dendrobium Parishii*, *D. Bensonia*, one of the very finest of all the Indian Dendrobiums; *Epidendrum vitellinum* major, with two spikes of remarkably fine richly-tinted flowers of a glowing orange-scarlet; *Cypripedium barbatum*, *C. Veitchii*, and others. In another group were well-flowered plants of *Phlox paniculata*, *Delphinium*, *Delphinium*, and *Cattleya citrina*, with lemon-scented flowers of wax-like consistence. Some fine stands of cut Roses were staged by Mr. William Paul, of Waltham Cross. Fine Pelargoniums were exhibited by Mr. Donald, and Mr. Ward was first in the class of six fine show varieties. Ferns came from Mr. J. Lane, Romford; and Mr. Simmonds also staged a very good group. Collections of *Hydrangeas*, zonal and treed Pelargoniums, *Fuchsias*, *Colons*, *Lilies*, and other decorative plants, made up a very interesting exhibition.

Fruit.—Mr. Richardson, of Lordship Lane, Tottenham, furnished a Black Hamburgh Vine in a pot bearing seven fine clusters of fruit; also a Golden Hamburgh equally fine. Excellent Cucumbers came from Mr. J. Douglas. Melons from Mr. Stephenson and Mr. Douglas, who also staged three splendid clusters of Black Hamburgh Grapes. Mr. Bone being second. While those staged by Mr. J. Lane had wonderfully fine berries, but rather small bunches. The first prize for White Grapes went to Mr. J. Douglas, who had nice clusters of Buckland Sweetwater. Mr. Bone occupying a corresponding position with three nice bunches of Muscat of Alexandria. Peaches and Nectarines of excellent quality came from Mr. Stephenson; and splendid Strawberries were furnished by Mr. E. E. Wythes, of Epping, and others. Cherries were remarkably fine, especially a dish of Black Hearts staged by Mr. Chambers, gardener to H. Fowler, Esq., Woodford. Excellent Gooseberries and Currants came

from Mr. Bant and Mr. Simmonds. Vegetables, as has been stated, were but poorly represented as to quantity, a thought of four quality and appearance. Mr. S. Deard exhibited his patent boiler, an excellent and economical one for small greenhouses, hothouses, and others. Messrs. Denton & Co. had a well-arranged group of garden vases and other garden contrivances of a smaller kind; Messrs. Middleton & Son, of Bishopsgate Street, staged some elegant crystal flower stands and other table decorations.

WINDOW GARDENING.

EARL SHALLESBURY distributed, the other evening, prizes to the winners in a show held in the Old Palace Gardens, Westminster, of the window gardens of the labouring classes—men, women, and children, domestic servants, and patients of Westminster Hospital living in the united parishes of St. Margaret and St. John's, Westminster. The show was extensively patronised by the higher classes in the course of the day, and it furnished a good display of window flowers, some evidently reared under difficulties, in London-made boxes, others being taken from the owners' best brought forward as well as care to bear upon the objects of their culture. Dr. Hooper contributed a box of curious plants from Kew, but the large number of plants exhibited were Geraniums, Fuchsias, Nasturtiums, *Cheering Daisy*, the "Golden Feather," *Panicles*, and other gay and ornate adorned London window-sills. The prizes consisted of some really good books, principally on subjects connected with animal and floral nature, well written, well bound, and well chosen, forming a remarkable contrast to the "goody-goody" class of literature which was formerly given at prize presentations. Money prizes were also given, and in all there were about 100 recipients of gifts, a large number of whom were children. The Dean of Westminster, the Lady Augusta Stanley, the Rev. Canon Conway, and Mr. J. G. Talbot, M.P., were present, and Lord Harchester and other noblemen gave their patronage to the pleasant movement. The gardens were well filled during the evening; and, after the speeches, a band played various selections.

Crystal Palace Show.—We are requested to state that Mrs. Ramsley Tanton, of Epsom Nurseries, obtained the first award in the class for button-hole bouquets at the exhibition which took place at the Palace on the 29th ult., and not Mr. J. E. Rose, as stated in the official report.

Bremen International Exhibition.—A medal for merit was awarded to Messrs. J. E. Brown & Co., London, for excellence and perfection in workmanship, and cheapness of production of their Galvanised Wire Netting.

THE GARDEN.

NOTICES TO READERS AND CORRESPONDENTS.

The name and address of the writer are required with each communication; the sending of a card once will not suffice, as different correspondents frequently change the same name de plume. Letters and inquiries from correspondents not reaching their full name and address (in addition to any name or initials they may wish to use in THE GARDEN), to which we reply by post when that course seems desirable, will not receive attention. Not more than four kinds of plants or fruits can be named in one time. Quizzes and communications for the paper should be written on one side of the paper only. Correspondents will greatly oblige by forwarding photographs or sketches of particular garden scenes, fine trees, &c., for insertion in the pages of THE GARDEN. All communications in order to be printed, should be addressed to "The Editor of THE GARDEN," and not by name to other numbers of the sheet. All communications, and all that should be kept in hand, and addressed to the Publisher, 37, Southampton Street, Covent Garden, London, W.C.

THE GARDEN is published in monthly parts, and in half-yearly volumes. Vols. I., II., III., and IV. of THE GARDEN, are on sale. Price, Vol. I., Cloth Gilt, 21s.; Vols. II., III., and IV., 12s. each. Binding-cases for Vols. I., II., III., and IV., now ready price 2s. each. Reading-cases, fitted with Elastic Bands, 2s. 6d. each. The best way to procure the Reading-cases and Binding-covers is to order them through a Newsagent. Back Numbers of THE GARDEN of Vol. I., are double price 8d. each.

PEAT EARTH.—Fibrous Peat Earth for American and New Holland Plants, Lianas, and for Potting; delivered on rail at Blackwall, South-Eastern Railway, and Farnborough, South-Western Railway, in truck-loads of 4 tons and upwards, at 12s. 6d. per ton; extra fibrous quality, for Orchids and Ferns, 25s. per ton; Sphagnum Moss, for Orchids, 10s. per sack.—T. WALKER, at Cannon Street, London, E.C.; where samples can be seen.

COVENT GARDEN MARKET.

JULY 3RD.

THE market is just now well stocked with excellent produce of all kinds. Large importations of Pines, Melons, Cherries, and early Apricots have been received, and these are much cheaper in consequence. Home-grown fruits are very good, and include fine Strawberries, Melons, Pines, Cherries, Grapes, Peaches, Nectarines, and Figs. Vegetables are of excellent quality, Peas and Potatoes being unexceptionally good. Cut flowers consist of orange and white Lilies, Pinks, Roses, Fuchsias, Blue Cornflower, Water Lilies, and wild Grasses. Very beautiful bouquets are now made of Gardenias, Roses, Carnations, Stephanotis, Pinks, Carnations, Bouvardias, Mignonettes, Heliotrope, and other choice sweet-scented flowers.

Cut Flowers.		s.	d.
Chrys. blooms, per doz.	...	3	0 to 9 0

OBITUARY.

The death is announced, on Monday last, of the Rev. C. A. Johns, whose works on botany and natural history have attained a wide popularity. Mr. Johns, who was born in 1811, was a Fellow of the Linnean Society, and in 1849 was elected the first President of the Hampshire and Winchester Scientific and Literary Society. Among his best known works are his "Botanical Rambles," "The Forest Trees of Britain," "A Week at the Lizard Point," "Ramble in the British Isles," "Flowers of the Field," "Gardening for Children," "British Birds in their Haunts," and "Home Walks and Holiday Rambles." Not the least successful of his works were those written specially for children. He died at his residence, Winton House, Winchester.

THE GARDEN.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

GARDEN FETES.

THE garden *fetes* of the metropolitan district have become the most charming attractions of the London season, as the recent entertainments given by H.R.H. the Prince of Wales, in his beautiful gardens at Chiswick, and by Lady Holland, at Kensington, and others of a similar kind prove. It is also admitted that the general characteristics of garden *fetes* have greatly advanced in attractiveness since the days when the late Duchess of St. Albans' breakfasts at Holly Lodge, were looked forward to as the climax of the festivities of the London summers of those days. Both then and now (but now far more generally) the charms of social gatherings among trees and flowers, with the air cooled by gentle and refreshing breezes, were, and are, acknowledged to be far more agreeable than assemblies in crowded rooms with an insufficient supply of fresh air, and too little space. The garden party certainly possesses great advantages over those indoor crowdings, especially when the average temperature is about 153° Fahrenheit in the sun, and 80° in the shade, slightly intensified by the presence of a comet rapidly approaching its perihelion, as at the present time. Last Wednesday was one of the most glorious, at all events one of the hottest, July days of 1874, and, by a happy conjunction of circumstances, one might pass nearly the whole day among trees and shrubs and human flowers, almost as fair and beautiful as the flowers themselves. It was the day fixed for Mr. Bohn's annual "Rose *fete*" at Twickenham; where a few hours may be lounged away both pleasantly and instructively among the rich collections of trees and shrubs. We have not space to speak of Mr. Bohn's Roses, the flower-deities of his *fete*—but beautiful as they were, and always grown in large masses of plants of each variety, which greatly adds to their effect—we must quit them hastily, in order to prepare for the garden *fete* of the season—the evening *fete* at the Botanic Garden in the Regent's Park. The first tentative *fete* of the kind in these gardens took place in 1872, when the arriving guests were greeted by a heavy thunderstorm, which, though it afterwards cleared off, yet left the Grass too wet to be dried even by the profusion of blue and red fire, which changed the great rain-drops into sapphires and rubies. The night *fete* of 1873 was more favoured by the weather; but for the floral games of 1874 was reserved the exquisitely beautiful night of July the 8th. The purple sky was quite Italian in the depth of its hue, and the new comet was the observed of all observers, to the occasional neglect of the many-hued fires that fitfully lighted tree-tops, and threw coloured gleams across the turf, and among the silks and satins and laces of the promenaders, with a fairy-like effect, that would have driven a Watteau to despair. The whole arrangements of lighting were, indeed, a great success. The festoons of white gas-lighted globes on each side of the broad walk, with a rosy-tinted one at the point of each of the supports, produced a very brilliant effect, and so lighted up the promenade and promenaders, that the illuminations may be fairly pronounced to have been what the Italians so expressively call "a *giorno*." Yet it was not precisely daylight, but seemed rather a kind of soft moonlight, even brighter than the light of day. But what would all this have been without the glorious weather, which will make this *fete* a memorable one in the annals of the *fetes* of the "Botanic?" and what would it have been without the charming laying-out of the garden itself, which, by the good taste of Mr. Marnock, has made the garden in the Regent's Park one of the most beautiful spots in Europe? The arrangements for the accommodation of Royalty made it somewhat difficult to get round the conservatory to the principal exhibition tent from the top of the broad walk, there being but a narrow space left at either end of the terrace (between ropes) for the vast crowds of spectators to crush through; but the fineness of the night, the general beauty of

the scene, and the exuberant loyalty of the British public, kept everyone in good humour, notwithstanding the uncomfortable crowding at those points, which might very easily have been avoided by roping off a sufficiently wide passageway. The first impression on entering the great tent was that, after the glorious glare of the gardens, it was altogether insufficiently lighted; for, while a few experimentalists were testing the lighting power of the magnesium light by reading the smallest print of the *Times* newspaper, the big letters of the prize labels in the tents were scarcely legible by the somewhat scanty supply of ordinary gas. It must be conceded however, leaving out all attempts to read the labels, that the effect of the subdued light was very soft and pleasing. The display of cut Roses was abundant beyond precedent, and the arrangement of them was fanciful and pleasing; but the extremely subdued light, and the fact of their being placed too far from the eye (upon the ground), rendered it difficult to judge of their excellence from a florist's point of view; though their exquisite perfume filled the air. The table decorations, as a rule, were pronounced inferior. A public, very exacting in its tastes in such matters, has been educated by the productions of our great gardeners, the deftly-skilful fingers by which they have been displayed for some years past, and the beautiful vase-forms invented for their reception have produced such happy combinations that the public taste has grown fastidious, and is by no means easily satisfied, and such uncomplimentary exclamations as "poor!" "spotty!" "no ensemble!" "trivial!" "bad!" were bandied freely about; and there was an outcry that some of the first prize objects were not always to be found. A few general principles appeared to have established themselves in the public mind with regard to floral decorations for the table. The first was, that dark stands next the cloth for crystal vases, large or small, was a glaring mistake, the clear sparkle of the glass being, in every way, preferable. Upon this principle, even the graceful Fern-fronds, when allowed to lie on the cloth, were disapproved of; and such remarks were heard, as if these fronds were swept away and the clean clear base of pure glass left undisturbed upon the cloth—a glistening icicle upon a field of snow—the effect would be much more cool and charming. Another principle arrived at appeared to be this, that small masses of the same flowers, say masses of blue flowers alternating with white—or pink or crimson with white—the effect, lightened and blended with Ferns and Grasses, was more likely to be effective than the old many-coloured system. At the same time, it was admitted, that a free and natural arrangement, if truly artistic, was a higher class of floral decoration, but very seldom realised on account of its difficulty. Among the things remarked as novelties, were one or two sideboard decorations of rich and tasteful arrangement among many of execrable meanness and barrenness of design. Lamps with glass stands arranged as receptacles for flowers, the light plunging down among the flowers producing a charming effect, but several of these were considered spoilt by a mass of common paper flowers covering the shade. There was, also, great objection made to strings of barley-sugar, or glass beads among the flowers, producing a puerile and pastrycook effect of the meanest kind. There were, however, some cachepots of pure white porcelain, in which pots of fine-growing Maiden-hair Ferns were concealed, which were pronounced a success. Finally, there was a nobly-designed silver table piece, several feet long, with supports for flowers, which were artistically filled with grand Orchids and Lilies, which secured general admiration, notwithstanding the awkward nature of one of its chief features—Water Lilies growing out of looking-glass instead of water, which, it must be conceded, is rather a clap-net device, though looking-glass so used is dignified by the makers of such things by the plausible title of "a mirror lake." In conclusion, we may express a hope that in future years the floral element will be more worthily represented at such a great meeting as this. The few dinner-table and rather meagre decorations can surely be improved upon. The grand tent and the conservatory ought to be well filled, the conservatory on these occasions being devoted to the hot-house plants and Orchids. Its ordinary occupants might be placed in the open air for the occasion.

NOTES OF THE WEEK.

— SOME very fine Yuccas are sending up their flower-spikes in the Avenue Gardens in the Regent's Park, another proof among many of the great value of these fine plants for town gardening.

— NOTWITHSTANDING our repeated notices, in the advertisement columns, that every letter should contain the writer's name and address, we continually receive questions without them, and questions to which we can only reply by post.

— It is reported that the extensive garden belonging to the Draper's Company is to be disposed of for building purposes. It is several acres in extent, and lying, as it does, in a dense part of the city would be invaluable if formed into an open square or public garden.

— THE sub-tropical gardens in Battersea Park are now completed, and they present a very attractive display. The bedding-out in the various parks is now becoming very attractive, the mud-edgings, however, looking as ugly as usual. As regards the health and culture of ordinary bedding-plants, by the way, can anybody say what advantage they receive from being raised to the level of these plastered edgings?

— We learn from *Nature* that arrangements have been concluded between the proprietors of the *Daily Telegraph* and Mr. Bennett, proprietor of the *New York Herald*, under which an expedition will at once be despatched to Africa, with the objects of investigating and reporting upon the haunts of the slave traders, of pursuing the discoveries of Dr. Livingstone, and of completing, if possible, the remaining problems of Central African geography. This expedition has been undertaken by, and will be under the sole command of Mr. Henry M. Stanley. We suggest that a botanical collector should accompany this party if possible, so as to obtain some more definite knowledge of the luxuriant vegetation of the interior of Africa of which we know, as yet, so little.

— THE *Florist* of this month contains a coloured illustration of Messrs. Veitch's handsome orange-scarlet flowered Rhododendron, called Duchess of Edinburgh. It belongs to the Jasmine-flowered type, which includes, besides *Jasminiflorum*, the white blossomed Princess Alexandra, and the pink-flowered Princess Royal, and Princess Helena, all choice conservatory plants, to which Duchess of Edinburgh (a hybrid raised between Princess Royal and Lobii) is a splendid addition. Its leaves, which are about 2 inches long, are elliptic, glossy, and coriaceous; and the blossoms, which are borne in terminal umbels of from nine to twelve together, are strikingly showy. The same number also contains a coloured representation of the Barrington Peach, a well-known and excellent variety.

— AMONG plants now in flower on the rock-work at Kew, are *Lychnis Sieboldii*, a good plant of which is producing large white flowers tinged with pink in abundance; a white-flowered perennial species of *Lobelia*, called *littoralis*, which, if thoroughly hardy, will become a valuable plant for rock-work; *Helichrysum scorpioides*, a showy perennial Everlasting; *Hypericum balearicum*, a dwarf species, now thickly studded with yellow flowers; a distinct kind of *Sedum* called *sempervivoides*, with rose-coloured flowers, and a good plant of *Androsace lanuginosa*, with several umbels of pretty delicate rose-coloured blossoms. The herbaceous grounds at this establishment are now full of showy plants, among the rarer and most interesting of which may be mentioned *Dianthus ramosissimus*, a much branching wiry-stemmed kind with purplish-rose-coloured flowers; the trailing *Abronia arenaria*, with showy umbels of pale yellow flowers, and *Salvia chionantha* a showy white-blossomed species. *Ligusticum pyreneum*, a plant ornamental both in flower and foliage is also now blooming freely at Kew.

— COLLECTIONS of herbaceous and Alpine plants are now well worth a visit, many interesting plants, both new and old, being now at their best. For instance, the handsome *Morina longifolia* is just now in fine condition at Mr. Parker's establishment at Tooting, where a tuft of it is bearing no fewer than seventeen fine spikes of white and rosy flowers. Here, too, are to be seen, among a host of other attractive plants, *Omphalodes luciliae*; *Prunella pyrenaica*, one of the best of the genus; large tufts of *Rudbeckia californica*, a fine plant for the back of a mixed border or shrubbery; and a good tuft of *Jasione perennis*, having much larger and finer heads of bloom than those we have before seen on any plant of the kind. Among hardy aquatics, for which this place is famous, we noticed *Sagittaria obtusa*, a somewhat scarce plant with white flowers, which, when fully established, will doubtless prove itself worthy of general attention. At the Wellington Nursery, St. John's Wood, there are, also, many attractive plants now in flower, among which the following, on account of their rarity, are most worthy of mention, viz.:—*Campanula Zoysii*, a smooth-tufted and very distinct species of Bell-flower, scarcely 3 inches high, a mass of pale blue flowers, which stand erect on the stems; the handsome *Silene Elizabethae*, a

kind with bright rose-coloured flowers; *Linum salsoloides*, of which there is a good specimen nicely in flower, and *Lychnis Bungeana*, of which there are several fine varieties blooming in such perfection as to clearly indicate that, when more common, they will make useful border plants.

— THE scarlet-berried Elder, so often seen on the Alps, is now covered with its ornamental berries in Mr. Harrison Weir's garden in Kent. It deserves to be more frequently planted than it is.

— It is important to notice the striking improvement effected in St. Paul's Churchyard by the removal of the railings to the west of the Cathedral; St. Paul's itself, and the whole of the surroundings seem altered for the better by this simple process. Many of our buildings and their surroundings are greatly disfigured by needless railings—those miserable barriers which suggested to a witty writer the remark "Thieves without and nothing to steal within."

— WE have just received from Colonel Marshall P. Wilder, of Boston, the new number of the "Proceedings of the American Pomological Society, by far the most useful and well-stored thing of the kind we have ever seen. It is in every way worthy of the country which is destined to become the greatest fruit-growing region of the earth, and contains a mass of matter of great practical value to American fruit-growers and, in a lesser degree, to ourselves. The paper and printing are of a character superior to what we usually meet with in the best works published in this country.

— A PAINTING of the grounds at Oak Lodge, Kensington, often alluded to in these columns, is now on view at the house of M. Arsène Houssaye, Avenue de Friedland, Paris. It is the work of M. Ollivier Pichot, and has for its subject the visit paid in 1872, by the Emperor Napoleon, the Empress Eugénie, and Queen Christina, to the villa of Mr. MacHenry, in Holland Park. The Royal and Imperial party with their attendants, the host and hostess and their family, are represented walking through the grounds of the MacHenry villa. A piece of water in the foreground is charmingly painted. The figures are all portraits.

— THE last number of "Jeunings's Orchids, and How to grow them in India and other Tropical Countries," contains coloured plates of *Maslevallia Lindenii*, a fine plant bearing lilac-purple trifid flowers; *Cattleya gigas*, sometimes known as *C. Imperialis*, with rosy-purple sepals and petals, and a great margined purple lip with deep veins; *Dendrobium Boxallii*, with white flowers like those of *D. Bensoniæ* in form, with white sepals and petals tipped with lilac, the lip being blotched in the centre with clear yellow; and *Aërides Fieldingii*, the common "Fox-brush Orchid," an old favourite with dense gracefully drooping branched spikes of rosy-purple flowers.

— *Lilium giganteum* is now in fine flower in Professor Owen's garden, at Sheen. It was only planted out a year last spring. Its odour fills the garden. Few people seem to grow this most stately of the Lilies, though it is hardy on light warm soils. We have seen the plant flowering freely in Messrs. Dickson's Nursery, at Edinburgh, and Mr. Outram, in the *Gardeners' Record*, tells of its succeeding well in Scotland:—"Lilium giganteum stands out-of-doors at Gordon Castle, as far north as Banffshire, the seat of the Duke of Richmond, proving itself quite hardy in that locality. When I visited these gardens on June 23rd, plants of it were from 6 to 8 feet in height, showing fine spikes of bloom. Mr. Webster, the gardener there, showed me dried flower-spikes, the result of last year's growth, upwards of 12 feet high, which had each produced two dozen and upwards of flowers."

— OF the following plants coloured illustrations appear in the current number of the *Botanical Magazine*—viz., *Chrysanthemum eatanancho*, a dwarf cut-leaved Composite, which forms silvery tufts a few inches in diameter, and bears pale yellow flowers as large as those of the common Marigold or *Gazania splendens*. Like the last-named plant, a purple ring enriches the fertile florets of the disc. It is found at an elevation of from 7,000 to 9,000 feet on the Greater Atlas, and flowered at Kew in April of the present month.—*Erica chamissonis*: a ternate-leaved rosy-flowered species from Southern Africa.—*Romanzollia sitchensis*: a dwarf decumbent herbaceous plant from North-western America, about 6 or 8 inches in height, with crenulate reniform leaves, and scarpoid panicles of white flowers about half-an-inch in diameter.—*Iris obiensis*: a showy species, with the habit of *I. pumila*; but with larger and more durable flowers. Its blossoms, which are produced in April, are rich purple, and as handsome as those of a *Cattleya*. It is a native of Northern Italy and the South of France.—*Campsidium chilense*: a pretty climbing Bignonaceous shrub, introduced by Messrs. Veitch, with whom it bloomed early in spring. It has bright green foliage, and drooping clusters of deep rosy tubular flowers, with an expanded five-lobed rim. It is a native of Chili, and a desirable plant.—*Pyras baccata*: a highly ornamental tree from the Himalayan range, bearing snowy-white blossoms in dense clusters, succeeded by globular fruits as large as marbles, and of a golden-yellow colour, tinged with crimson on the sunny side. It is perfectly hardy.

THE FLOWER GARDEN.

THE COBWEB HOUSELEEK.

IN many gardens this interesting little mountaineer is a novelty as yet, and its curious downy covering and strange aspect generally, leads many to doubt its hardiness and constitutional vigour. It is, however, as hardy and as easily grown as the common Houseleek. The Cobweb Houseleek is a native of many parts of the Alps, and I have this year been in districts where it occurred on every rocky place. It is on the flanks of the warm Maritime and Italian valleys, where the snow leaves it free to the sun early in spring; and it is also in the colder and more northerly Swiss valleys, where it only escapes from its prison house in early summer. It thrives perfectly in British gardens, but being frequently grown in pots and frames (which it does not enjoy so well as a suitable position in the open air) it may seem to some a slow-growing or a difficult plant. The proper place for it is on a rock-garden, and it will grow in any open sandy soil, the sole precaution necessary being to prevent it from being overrun by taller or quick-spreading plants. It does perfectly well on level borders of sandy loam in the London district, but in all cases where it is planted in a mixed border the plant or group of plants should be surrounded by a few half-buried stones which will keep off the hoe and rake, and the foot, and prevent evaporation. The best plants I have seen are at Lamport Hall, the seat of Sir C. Isham, in Northamptonshire, where they form silvery seams and tufts as good as I have ever seen on the Alps. There should be no difficulty in establishing the Cobweb Houseleek on an old wall or ruin or open stony place where it would not be overrun by coarser vegetation. It may, of course, be used with the various small succulent plants now grown in the flower garden. I once saw a splendid specimen of this charming little Alpine growing in a pot on the outside of a window at Bromley, in Kent, and so luxuriant was its growth that the silvery rosettes drooped gracefully over the sides of the pot until they nearly touched the edge of the saucer in which the plant stood. W.

PETUNIAS AS BEDDING PLANTS.

AMONG summer bedding plants none are better than some of the showiest of single Petunias, especially such sorts as have a dense short-jointed habit of growth, that flower profusely, and that have medium-sized rounded blooms of good shape

and substance. With such plants, no matter of what colour, whether all the same or mixed, a beautiful mass of flowers may be obtained from the moment the plants are turned out at the end of May up to the end of October. Of all the shades of colour to be found in the Petunia, none are so pleasing as those of the striped kinds; for, unless propagated from the same plant, no two are exactly alike; and, even the same plant, often furnishes much diversity in the way of markings, although the colours are identical. A good striped strain ought to be devoid of any large loose laced flowers, huge blooms that are all points and folds, and that get torn to ribbons in the first gale of wind to which they are subjected.

For some seven or eight years I have been growing annually from seed a good number of plants of the striped forms, and by means of constant and careful selection, I have so far got rid of all self-coloured flowers, that not one plant in a hundred yields other than good striped blossoms. In some cases the ground-colour is white, striped with crimson, purple, or red-rose, and, in others white stripes are laid on a dark ground colour. Some of the flowers are, perhaps, more showy than others; but in all cases, if the variegation is present, and the shape of the flower perfect, the effect is most satisfactory. Self-coloured flowers also make most effective masses, but these look best when in distinct colours. Countess of Ellesmere, a well-known rose-coloured kind with a white throat, is a very pleasing variety; so is Warrior, a rich crimson; and there is a deep crimson-purple kind called Spitfire, that also furnishes a rich and most effective hue of colour. I once saw the last named kind planted thinly amongst a bed of silver-edged Pelargoniums, above which the dark purple blooms of the Petunia came up freely, and with excellent effect. Most of these kinds, if grown apart from others, will reproduce themselves from seed; but, as a rule, plants raised from cuttings seed but little, whilst seedling plants, especially of the white and striped kinds, seed freely. Our best single white self has smallish flowers; but the habit of the

The Cobweb Houseleek (*Sempervivum arachnoideum*).

plant is coarse, and the growth rank, so that a neatly rounded mass of this variety is never obtained. Some of the striped forms yield nearly white flowers, but these are unreliable, and are at all times liable to revert to dark shades. There are also some prettily veined flowers, a few of which are worth growing, but, as a rule, they are inferior in decorative effect or beauty to richly coloured selfs or the striped forms.

Than Petunias, few plants are more easily propagated, either by means of cuttings or seeds. Cuttings should be put in early in September when the wood is short-jointed and firm.

They will strike freely in 6-inch pots, filled two thirds up with moderately good compost, and the remainder with a mixture of sharp sand and soil. Place them on a shelf near the glass during winter; give them little water, and they will make growth enough to furnish cuttings about the end of March, and if in April, the stock plants themselves be potted up singly, a good stock of bedding plants will be secured.

Seed may be sown about the middle of September, and the seedling plants kept in pans or boxes through the winter; or it may be sown in February under glass, and, if possible, in a gentle heat, when good plants may also be produced in time for bedding out. I invariably sow about the middle of September, in a shallow pan which has been previously filled with a fine sandy compost. The soil on which the seed is sown should be kept just moist until after the plants are well up, when they may be watered freely. When about an inch in height they should be pricked out thinly into other pans or boxes, and in these they may stand through the winter, and be potted up into 60-sized pots early in the spring. The double forms of the *Petunia* make very useful pot plants, but they are not desirable for bedding purposes. The blooms are usually heavy and full, and, when wet with the rain, lie about in an ungraceful fashion, looking anything but pleasing. As pot plants grown under glass they are not subject to this misfortune; and, if the plants have been well grown, are robust and stocky, and, if they have been well pinched during the earlier stages of growth, good heads of flower will be the result. *Petunias*, whether double or single, make very showy exhibition plants; and, if well grown, are invariably admired because the hues of colour are well toned and the reverse of gaudy. I should like to see the *Petunia* more generally encouraged at our horticultural exhibitions.

ALEX. DEAN.

Bedford, W.

SAXIFRAGES.

By J. C. NIVEN, Botanic Gardens, Hull.

The Wandering Jew Group.

THIS very distinct group is represented by four well defined species, to which Borkhausen gave the appropriate generic title of *Diptera*, thus separating them from the *Saxifrages* altogether. Seeing, however, that the popular will has never endorsed the new title, it must be considered as nothing more than a technical term applied to this special section. One of its peculiarities—as indeed the name, which literally means two-winged, expresses—consists in the inequality of the petals, as regards size. When Borkhausen established his new genus, the two species then known had irregular flowers, consisting of three small petals and two large ones, the latter, being three or four times the size of the former and pendent, had somewhat the appearance of two wings. Recent discoveries have, however, brought to light another species, in which there is but one large petal, hence the original appropriateness of the name *Diptera* has become somewhat marred. A second peculiarity presents itself in the very habit of the plant, with its long slender trailing sarmentose stems, reminding one, by its growth, of the “runners” of the Strawberry. All the species in this limited section are of Chinese or Japanese origin, and appear (in spite of their “Wandering Jew” designation) to have, like the Celestials themselves, believed that their native country represented the entire world, and confined their rambling propensities thereto.

S. sarmentosa (of the younger Linnaeus) has as synonyms *S. stolonifera* of Jacquin and *S. chinensis* of Loureiro; it is the trailing plant that we not infrequently meet with in cottage windows, under the popular name of the Wandering Jew, or sometimes under that of the “Mother of Thousands.” The latter title is, however, more generally claimed by the *Linaria cymbalaria*, though equally, if not more appropriate to our trailing Saxifrage. Its leaves, when growing vigorously, are fully 4 or 5 inches across, convex-rotund, and broadly indented, laxly covered with erect hairs and blotched with white, giving it quite a variegated appearance. The foot-stalks are dilated and fleshy at the base, clothed, as well as the back of the leaves, in a young state, with crimson hairs. The stolons originate from the axils of the lower leaves; they are long and thread-like, either simple, as in the Strawberry, or branching—a bud, which ultimately develops into a perfect plant, is produced at the extremity; this, after establishing itself in the ground, assists in the continuous

growth of the stem proper, its onward progress being only checked by the periodic arrestment of growth necessary to secure a fresh root anchorage, and the development of what were buds originally into perfectly independent little plants. When suspended in a pot, of course the rooting process is omitted, and the buds constitute a series of plantlets, extending through a series of generations. The inflorescence consists of a very lax paniced cyme, about 12 inches high, carrying six or seven flowers on each secondary division, the whole of the stalks and calyx being covered with glandular hairs; the two lower petals are large and of a creamy-white, the upper ones small, pinkish, and dotted with a few distinct crimson spots. Surrounding the ovary is a largely developed disk of a brilliant orange colour, which materially adds to the beauty of the flower. This species is of no modern introduction, dating back to the last century, but by whom introduced, or through what channel, I cannot ascertain.

S. cuscuteæformis of Loddiges, and figured by them in their “Cabinet,” is considered by some as only a minor form of the previous species; but, surely, it has full title to all the honours of a specific distinction. Its leaves are broadly oval, varying in size from a three-penny piece to that of a penny, or even larger, perfectly flat on the surface, the margin broken by a few broad but slight indentations; there are no blotches on the leaf, but every vein is picked out with a silvery whiteness that reminds one of the *Eranthemum argyreneum*; its runners are as slender as the finest thread, or, even, hair; the flowering-stems do not attain a height of more than 5 or 6 inches, each bearing two or three blossoms, whose large developed lower petals are remarkable for the purity of the white. This species is far more tender and delicate in its constitution than old *sarmentosa*, and it delights in a moderately moist atmosphere, its slightly fleshy leaves being highly insusceptible of hygrometric changes; hence, the very best place to grow it is on the back wall of a cool Fernery, where it can throw out its hair-like stolons and insert its roots into the crevices of the damp bricks, where, in the course of a season or two, it will form a beautiful mosaic with its silver-veined leaves, all the purer and brighter for the shade which such a situation affords it. There appears to be some doubt as to its native country; Engler gives it as Japan, with a query; but I should not be at all surprised if it does not turn out to be an Abyssinian plant, as I came across a few dried fragments of Abyssinian vegetation that had been gathered by a soldier in the late expedition, and I have very little doubt, in my own mind, that one leaf was that of our little Dodder-like Saxifrage; if so, this group will claim a wider range than has heretofore been assigned to it.

S. cortusæfolia of Siebold and Zuecharini takes precedence of the name *S. japonica*, with which we are in this country more familiar, and under which it was introduced and distributed by Messrs. Fortune & Standish. In appearance it claims a much closer relationship to *sarmentosa* than the last species. It is, if anything, a more vigorous grower; its leaves are a dark green, orbicular in shape, and slightly seven-lobed, covered with long, erect, crimson hairs, which hairs are so densely arranged on the leaf-stalks, and also on the young leaves, as to give a very important character to the plant; its creeping stems are developed with great vigour, and are beautifully crimson in colour; the large petals in the flowers—which, by-the-way, are produced in good bold panicles—are three-nerved, whereas, in *sarmentosa* they are but one-nerved.

S. cortusæfolia var. *tricolor* is a charming variegated form, introduced also by Mr. Fortune. In it the golden variegation contrasts beautifully with the crimson hairs, but it is far from constant in its parti-coloured state. It is of stunted habit; and, as soon as vigorous growth sets in, the plant loses its variegation, and reverts back to its normal condition; were this not so, it would be one of the loveliest plants we have for a suspended basket. I well remember seeing the first importation of it at Mr. Standish's nursery, and being perfectly charmed with it. Possibly, some of my readers may have been more successful than myself in dealing with this variety; if so, I should be glad to glean the result of their experience.

S. Fortunei of Hooker is a plant perfectly distinct from the foregoing species, in the fact that it does not possess the rambling character at all. Although Dr. Hooker, in his description accompanying the figure in the *Botanical Magazine*, appears to have assumed that it would ultimately develop runners, I have, after cultivation for a series of years, never noticed even the slightest tendency in this direction; nay, the reverse, as its foliage appears to spring from a sort of fleshy, and indeed flesh-coloured, bud, to which the offsets are so closely attached that they are with difficulty separated. Fortune's Saxifrage is, in spite of this important distinction, correctly referred to this group. Its leaves are 2 to 3 inches across, rotundly reniform, or, perhaps I ought to say, reniformly rotund, of a thick leathery substance, and moderately lobed; as to the margin, concave and glabrous, if I except the presence of a few scattered hairs; but so far separated

are they, that they scarcely militate against the appropriateness of the term glabrous. Its flowers are produced in tolerably dense pannicled cymes; they are white, with a tinge of green, and have only one of the lower petals enlarged, the four smaller ones being entire as to the margin; whereas the large one is deeply lacinated, or almost lobed. The time of blooming in this plant is about the month of November—quite an exceptional thing among Saxifragas. In mentioning this fact, I am reminded that the number of Chinese and Japanese plants that bloom in the winter time is very considerable. Why such should be the case I can hardly explain. As to the hardness of Fortune's Saxifrage, though I have not fairly tested it, I am disposed to fear that our winter's severity will be against it. Be that as it may, a plant that naturally comes into blossom in the cheerless month of November, and lasts till Christmas, is by no means to be despised, and is well worthy the protection of a frame, which is all that it requires.

DOG'S-TOOTH VIOLETS.

[MR. ANDREW MURRAY, who has recently travelled over portions of the Rocky Mountain region, has communicated the following highly interesting notes on Erythroniums to the Scientific Committee of the Royal Horticultural Society.]

The yellow Dog's-tooth Violet occurs in vast numbers, covering acres with its bright and glowing flowers. One of its habitats is easily accessible from Salt Lake City, being within two hours' walk of it. It travels perfectly well in the bulb, and scores of bulbs that I sent by post wrapped up in oilskin reached England safely for a postage of a few pence. I sent all my living plants in this way through the post, and, with the single exception of an Iris, which I begin to think must be an annual, all seem to have arrived in safety. It has, moreover, the great advantage of growing within a considerable range of altitude. As I just said, it is found on the very crests of the hills, covering considerable spaces, but the first time I met it was in a small glen called the City Creek, running up from Salt Lake City and at no great elevation above it. It was a lovely morning in April, the sun beating strong into the glen or canon, the tiger beetles had just come out and were flying strong and vigorous, settling constantly on the road which meandered up the glen parallel to the stream that murmured by its side, and numerous butterflies flitting and sailing about—the American variety of the Camberwell Beauty was especially numerous and fine. I had gone about two miles up the Creek to a point where some conglomerate rocks, with caves and holes in their faces, said to have been a few years ago the abode of the grisly bear, began to contract the sides of the glen previously to opening it up somewhat wider a little higher up. The sides of the rough road and the sides of the stream itself were clothed with Willows, Poplars, Rose bushes, &c.; and the undergrowth chiefly consisted of the Holly-leaved Berberry, which grows everywhere up such glens in profusion. It was not so beautiful, however, as I expected; trodden down by man and beast it looked broken, damaged, and imperfect, for the cattle of Brigham Young, and his tenants wander over all these hillsides. The Mahonia aquifolium, therefore, in a wild pastoral country is rather a failure, though it would probably be different were there nought but Indians, deer, and bears to admire it; still even now its glossy leaves and bright yellow blossoms are refreshing and pleasing to the eye, although not to be compared with its beauty in our own country, where it is protected and cared for. Pushing along, through this and the shrubs along the river-side a bright yellow flower, something like a small hooked Daffodil, caught my eye, growing some distance ahead in a moist bend of the road among the roots and under the shade of the Mahonia and Burr Oak. "Can this be a Daffodil?" said I to myself; "I did not know that there was any in North America." I drew near, and found that it was not a Daffodil, but a large bright yellow Dog's-tooth Violet, with its petals curled back like those of a Tiger Lily. The first one that I saw had only one head; presently I saw another with two flowers on the same stem; then one with three, and on up to half-a-dozen. I was immediately on my knees grubbing at them with my knife; but it was no easy task. The longer stem seemed as if it would never show its bulb. Perseverance, however, as usual, met with its reward; several bulbs I lost by the stem breaking or becoming involved among the matted roots of the Mahonia or Burr Oak, but I got a few, and resolved to return next morning, like Oliver, and search for more. I had no botanical books with me, but a Salt Lake friend fortunately possessed a copy of Dr. Sereno Watson's recently published quarto on the "Botany of the Fortieth Parallel," being part of Clarence King's report on that region, and, having recourse to it, I made my *trouaille* out to be the Erythronium grandiflorum of Hooker. Next day I was back to the same locality, and found one or two additional habitats, all on the City Creek Glen or canon.

While I was busily occupied in obtaining a few more bulbs I was aware of some one approaching, and looking up I saw a young man carrying a gun, looking on benignantly at my operations. "A botanist?" says he. Instinctively I felt that he, too, had been touched by Ithuriel's spear, and on inquiry *more scotico* I found that it was so. He knew a little of botany, and was able to give me the names of a good many of the surrounding commoner American plants, which were new to me. I inquired if he knew this Erythronium, and said I supposed it to be grandiflorum. "No," said he, "that is not the grandiflorum; it is white and larger. I can show you where it grows, higher up;" and he did accompany me in search of it, but missed it. What he spoke of is the white variety, described as albiflorum, and he also mentioned a pink one; these are certainly to be found in the neighbourhood, although I missed them. We did not find his white Erythronium, but we saw plenty of the yellow species or variety of which I am speaking, and as I was by that time armed with a prospector's pick instead of an insufficient knife, I was enabled to make a very good haul of bulbs.

Passing, however, from the getting of the plant to the plant itself as it has now been introduced into this country—and will, I doubt not, be hereafter sent over in still greater abundance—the readers may, perhaps, like to be reminded of what we know about Erythroniums in general, and more particularly of the species in question. Everyone knows our common Dog's-tooth Violet, Erythronium dens-canis. It is that species that has supplied the derivative of the generic name, *ερυθρονος* (red), a name by no means applicable to the majority of the species, seeing that most of them are yellow or white. The *E. dens-canis*, although common in our gardens, is not a native of Britain, but in Switzerland and other parts of Europe it is common. It also extends all the way across Asia to the Pacific coast, through Southern and Temperate Siberia, Baikal, Dahuria, &c., where it assumes at least three different forms or varieties—the common one, one called *E. sibiricum* by Fisch, and another called *E. parviflorum* by Regel. This, I believe, is the only old-world species. Two other supposed species, one (*E. bifida*) with a bifid style, and another called *longifolium*, from Switzerland, have been described by Sweet in his "Flower Garden;" but they are only varieties. America is better provided with species. The Atlantic slope of the Continent has two—one (the common yellow Adder's Tongue), *E. americanum*, of which *bracteatum* (Boott) is a var., is yellow, and has the green leaves spotted with purplish and dotted; the other, *E. albidum*, has a white or bluish-white flower, and the leaves spotted but not dotted. The other names (*E. Nuttallianum* and *E. Carolinianum*) are either varieties or synonyms of these. Now, with reference to these two species, I should like the reader to note what are the distinguishing characters, for he will presently see that exactly similar differences occur in the varieties of the Erythronium of the Pacific slope; and if what is said for the goose should be said for the gander, it would appear to follow that either the two eastern species should be united, or the varieties of the western species should be separated into different species. At the same time, I should note that in speaking of the second of the eastern species (*E. albidum*) I do not myself know the plant, and speak only from Prof. Asa Gray's description in his "Manual." The differences then between *E. americanum* and *E. albidum* are these:—

<i>E. americanum.</i>	<i>E. albidum.</i>
Leaves—spotted with purplish and dotted.	—spotted but not dotted.
Perianth—pale yellow, spotted near the base.	—white or bluish-white.
Style—club-shaped, stigmas united.	—club-shaped, stigmas 3-cleft.

On the western side of the Rocky Mountains we have the species *E. grandiflorum*, which has led us to this subject. It was first described by the late Sir William Hooker in the *Flor. Bor. Amer.* ii. 182, and four varieties indicated:—

1. *E. grandiflorum* var. *minor*, Hook.; flower, yellow, and single on the stem; leaves, green, and not spotted; stigmas, united, and brought to a point. This is figured by Lindley in the *Bot. Reg.* t. 1716.

2. *E. grandiflorum* var. *giganteum*, Hook., Lindley, l. c.; flowers, yellow, from two to five flowers on the stem; leaves, green, and not spotted; stigmas, united and pointed.

As to these two varieties, there can be no doubt that they are one thing. In the large patches of them which I saw in Utah, every variety, from that with a stem with a single flower up to others with as many as nine or ten flowers on a stem, were to be seen growing together, almost as close as Crocuses in a nurseryman's flower-bed. Of this variety, therefore, we may say with Marc Antony, "Let this fellow be nothing of our strife. If we contend—out of the question wipe him."

3. *E. grandiflorum* var. *albiflorum*, Hook.; flower, white, only one

on the stem; stigmas, three-cleft, with the lobes entire at the apex; leaves, green, and not blotched.

This variety has lately been flowered by Dr. Regel, of St. Petersburg, and described and figured in the *Gartenflora* (August, 1873, p. 227), and the characters above given are taken from his description.

E. grandiflorum var. *maculatum*. Flowers same as last variety; leaves blotched.

I add this as another variety on the strength of the description given in their catalogue for 1873 by Messrs. Backhouse, of York, who have introduced it and flowered it in England. They describe it under the name of *Erythronium giganteum* (Lindl.)—the gigantic Dog's-tooth Violet—as follows:—"Think of a Dog's-tooth Violet growing 9 to 18 inches high, and bearing three to ten large flowers on one stalk, and a fine idea may be formed of this noble species. Our collector states that it forms a branching, somewhat confluent spike of flowers, usually of a creamy-white, shaded with delicate pink or purple; others are quite white, and others again of a light lemon-yellow. In some districts it is of a clear red-purple. The blossoms are individually 3 inches or more across, and very handsome, the petals being broad and well expanded. Foliage blotched and marbled with purplish brown. Months of flowering—February, March, and April."

I incline to think that in their native country April and May would better express the flowering months. Of all the varieties this seems to have differences of the greatest value. Generally speaking, one would feel disposed to admit as distinct two varieties which, in addition to other specialities have such a remarkable distinction as green leaves and blotched purple leaves, but here all the differences seem to be unstable, while the main characters are constant; thus, the bulb, which is peculiar is, I believe, the same in them all. It is of a peaked oval shape, and the rootlets spring out, not at the termination, but at about a third from the bottom. I do not think, therefore, that we can avoid coming to the same conclusion as Hooker and the American botanists, and regarding them all as mere varieties of one species.

Besides the above we have—

E. grandiflorum var. *Smithii* (Hook.), of which the flowers are rosy-purple, and one on a stem; and

E. grandiflorum var. *multiflorum* (Torrey in Pac. R.R. Rep. iv., p. 146). Flowers, bright lilac, yellow at the base on the inside; flowers, one to fifteen on the stem; stigma, club-shaped; leaves, not spotted.

It is obvious that these differ from the common yellow type in little but the colour.

THE ROSE HARVEST.

A WEEK ago the Rose harvest threatened to be like most of the other harvests of beauty which we have reaped this season, short though brilliant. Now that rains have come prospects have brightened; our Roses will abide with us for a reasonable time, and many of them promise to be, after all, exceptionally fine. Conspicuous for quality are such varieties as Marie Baumann, Peter Lawson, Duke of Edinburgh, La France, Princess Mary of Cambridge, John Hopper, Maréchal Niel, Gloire de Dijon, Madame Barriott, La Rhone, Charles Lefebvre, Boule de Neige, Comte de Paris, Prince Camille de Rohan, Dr. Andrey, Victor Verdier, Madame Victor Verdier, Mdlle. Eugénie Verdier, Madame Fillon, Devonensis, Rose d'Or, and others, nearly all of which carry an exceptionally fine head of bloom. That magnificent Rose, Baroness de Rothschild, is later and shorter in the stalk than usual. Ipswich Gem, a pretty little Rose, almost too bright to look upon, has thrown out flowers of unusual size. I have also seen the following, specially fine this season, viz.:—Elie Morel, Ferdinand de Lesseps, Comtesse de Chab.illant, Alfred Colomb, Xavier Olibo, François Michelon, Camille Bernardin, Dupuy Jamin, Fisher Holme, Exposition de Brie, Madame Hector Jacquin, Madame Vidot, Louis van Houtte, Beauty of Waltham, Madame Bravy, &c. Most Roses that were pruned late in the spring carry a large head of bloom; whilst those pruned in autumn and winter are in many instances almost bare of buds. With a little more rain and dull weather to give the roots time, the late flowers promise to be by far the best, and the July Rose shows, including the grand show at Birmingham, are likely to be better supported with Roses than those that were held in June.

D. T. FISHER.

Rare Irises.—Can any of your correspondents tell me anything about the Irises known in catalogues as *I. Kämpferi*, I have never seen them in flower in any nursery or private garden, and though the description of them is very tempting, I fancy they must be very shy

bloomers. Max Leichtlin puts them down as *I. setosa* (Pall.), and says they only require to be planted in peat, but as peat is with me a very expensive article, and the varieties of this plant are mostly highly priced, I have not tried more than a few of them. From their names I suppose that they have been raised in Holland and Belgium, but of their history I can learn nothing. *Iris Monnierii*, a fine yellow species in the way of *ochroleuca*, from Crete, is now in flower with me, and *Iris violacea* (Klatt.), is just coming into bloom. Its habit is much the same as that of *Iris kievigata* (Fisch.) which I recently saw at Kew, and I expect it is the same plant. Is there any difference between *Iris tomiolopha* (Hance) sent out by Bull, and *I. tectorum* (Max)? I suspect not, but have not yet flowered the latter.—H. J. ELWES. [Messrs. E. G. Henderson have *I. Kämpferi* now finely in flower in their nursery at St. John's Wood. It is very variable, its six great purple petals being nearly equal, and all in the same plane, like those of a *Clematis* flower. Other varieties have but three fully developed petals. It is planted in ordinary garden soil, and, unfortunately, is not readily multiplied, being of slow growth.—F. W. B.]

Plants in Bloom early in May at Montpellier.—The following were in bloom at Montpellier when I left there on the 3rd of May, viz., *Nymphaea alba*, *Naphar lutea*, White Thorn (single and double, the former just over), Portugal and common Broom, Persian and common Lilac, *Pittosporum Tobira*, three kinds of *Robinia pseudo-Acacia*, *Rosa multiflora*, Horse Chestnut (white and yellow), *Laburnum* (nearly over), and *Guelder Rose*; while about London the following were in blossom on May 29, viz., White and Red Thorns, Horse Chestnut (nearly over), Red and Yellow Chestnut, *Laburnum* (the latter in the shade in bud only), and *Guelder Rose*, the last almost over. The whole line of country from Montpellier to the north of France, *viâ* Bordeaux, Tours, Paris, bore traces of the late frosts. In many places the Vines were much cut; the *Acacia*, Oak, Ash, and Apple, seemed to have suffered severely, especially when growing from stools, and in sheltered hollows; while the black Italian Poplar, Willow, Alder, Birch, and Hazle, had apparently escaped. From Dover to London I saw very little sign of frost; but here, in Richmond Park, the common Brake (*Pteris aquilina*) has been damaged to a great extent.—M. MOGGRIDGE, *Richmond, Surrey*.

Viola Munbyana.—This Algerian *Viola* is a well-marked species, growing on the summits of the whole range of the Atlas Mountains in Algeria. In Munby's "Flora of Algeria," published in 1847, it was mistaken for *V. calcarata*, and in Desfontaines' "Flora Atlantica," 1808, it was confounded with *V. cornuta*. Messrs. Boissier and Reuter first described it as a new species in their "Pugillus Plantarum Novarum" in 1852. Although sufficiently distinct from either *V. cornuta* or *calcarata*, it comes very near *V. lutea*, and the length of the spur of the flower appears to be the only well-marked distinction. Like *V. lutea*, its flowers are both entirely violet and entirely yellow, and clumps of it will have as many violet as yellow flowers. In cultivation it has withstood the hardest winters, generally beginning to flower about the end of February, and attaining its greatest beauty in May.—*Florist*.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Culture of *Tropaeolum polyphyllum*.—Will you kindly give me a few hints about *Tropaeolum polyphyllum*? I cannot make it do well. Ought it to be in full sun or partial shade? In rich or in sandy soil? I put a very good plant of it in the ground a little time ago, and it has quite faded away.—H. E. [This fine plant thrives well in deep sandy loam on the rock garden or in a border. There is sometimes, however, a little difficulty in establishing it at first.—Ed.]

New Semi-double Poppy.—We have received from Miss Hope, of Wardie Lodge, Edinburgh, specimens of a showy red semi-double Poppy, a seedling from *Papaver orientale*, crossed apparently with *P. bracteatum*. Miss Hope states that it grows short and robust, requiring no staking; that it is three weeks later than *P. bracteatum*, and that it lasts much longer than *P. orientale*. Its flowers stand well up above the leaves, which have a bluer tinge than the leaves of *P. bracteatum*.

Seed Sowing in Paper Pots.—A floricultural correspondent of *Moore's Rural* cuts good thick paper into three-cornered pieces, bends them in the shape of a funnel, fills them with soil, and, planting a seed in each, buries the whole in a box of soil. When the plants are ready to remove to the flower-bed, the paper and its contents are lifted out and planted like roots. The paper soon rots, and the plants never flag.

Colchicums Perishing.—I thought these hardy enough to take care of themselves, but some I put in last autumn have perished. Can this be checked in case of future planting?—H. E. [Bulbs are frequently injured by remaining too long in the shops or from being kept too long out of the ground, which is the same thing; when this is the case they very soon moulder away when put into the ground. Other causes could only be determined on the spot.—Ed.]

Culture of American Peat-loving Plants.—In reply to "H. E." (p. 6), allow me to say that no frame is necessary for a good many of these plants; many will flourish in an artificial or natural bog in this country, as, for example, the *Sarracenia* and *Orontium*; others, as *Cypripedium spectabile*, thrive perfectly in peat beds for American plants; *Trillium* also thrive well in peat beds in very shady places in shrubberies. It is not necessary to keep American bog plants "dryish" in this country in winter.—W.

THE GARDEN IN THE HOUSE.

SPANISH BALCONY GARDENING.

ENGLAND is, perhaps, more than any other country, a land of exotics, if we apply this term, not only to flowers and shrubs, but also to styles, fashions, and objects, which have been transplanted hither from foreign quarters. Amongst other importations from abroad is the vase, which occurs so frequently in buildings of the later Stuart days. In England it is a mere architectural ornament when met with on a house-parapet, with a certain beauty indeed, but no meaning or significance. It is usually a carved block of stone, incapable of holding anything, though of a form as if intended to hold something, and, moreover, it is generally placed in a situation inaccessible to anyone but a mason. When the vase has any use in England, it must, I need scarcely say, always be within reach of a watering-can or garden syringe. If we turn to countries from which these house-parapet vases have been brought, we find that they have both use and beauty, and furnish the means of gratifying one of the most refined and elevating of pleasures, viz., the culture of flowers. Fond as the English are of gardening, this taste, fortunately, is not confined to them. The wealthy Spaniard delights in his garden, high-walled if in a town, and with gratings through which he may look into the street, or through which the passer-by may see the Orange and the Almond blossom in spring, or if the garden be in the country, it is frequently railed in with cane-work, often very prettily plaited. Of course, water is the one thing needful for cultivation in Spain (I speak of the south), the famous gardens on the walls of the Alhambra having only about one yard of earth. The Spanish town lady, who frequently lives in a street often no wider than an English alley, cultivates flowers both in her balcony and on the terrace of her house. She is not, if unmarried, allowed to walk out alone; she, therefore, sits in the evenings in her balcony, to see and be seen, and surrounds herself with flowers, from the midst of which she converses with any friend who may chance to be passing; or she may be seen by those who have the advantage of a higher station-point walking about on the terrace of her house, watering a *dama del bosque*—Lady of the Wood, a very prickly Cactus, the hedge-hog of its tribe—or a Geranium, with water costing about one penny per gallon, and brought up to her by her servant in curiously-shaped earthen pitchers. The narrowness of the streets of a Spanish town are due, partly to the necessity of getting as much shade as possible, and partly to that of economising room where city walls exist. Space for a garden is a rarity; and flowers must, therefore, be cultivated in balconies and on house-tops, or not at all. The parapets are therefore made ornamental with vases, and in these pots of flowers are placed, and thus the propriety of usefulness with beauty is preserved. This, however, is not the limit of terrace-gardening in Spain. Flowers in earthen pots stand about on various parts of the house-top, just where they get the required sun or shade; and many pleasant hours have I spent on the terraces in Murcia, listening to the castanets and guitars in the street below. As to the utilisation of ornamental vases on English houses, it can scarcely be expected in so rainy a land as ours that flat roofs will ever become general; still, where they do exist they are very pleasant places, and if

the huge stone vases which sometimes adorn their parapets were hollowed out and flowers planted in them, their ornamentation would be much increased.

Spanish Street Gardening.

With reference to Spanish street gardening, there is a plant known in Murcia as the Picardia, much used for this purpose. It is a trifoliate creeping plant (apparently *Dolichos Lablab*), which will climb up a string to the height of from 20 to 30 feet. It is also very tenacious of life, and will grow not only in the open street, as shown in the accompanying illustration, taken in the Traperia of Murcia, but also in the gloom and dusk of a Spanish house, where we have seen it patiently growing up a staircase. In the patio, or court of their houses, the Spaniards also contrive to make a summer arbour by means of a circular arrangement of Picardias in pots, training the plants up strings to a hoop suspended between the galleries, as in the Casa de Noguea, a fine old house in the Traperia, and the white columns of the Casino are every summer wreathed round with this plant, thus giving an air of coolness in a

country where shade is a luxury. Why the Picardia should not be used in a similar manner in our own country during the heat of summer and autumn I do not know. It will succeed here, for I have had plants of it direct from Spain, growing equally well in the gloom of a London studio, and in the brighter atmosphere of a Sussex village. It is a hardy and a docile plant, growing in any direction in which one chooses to train it, and in whatever condition of life it is placed it seems to be always contented.

J. M. WOODWARD.

Northchurch, Berkhamstead.

Street Balcony Gardening in Murcia.

DRYING WHITE FLOWERS.

MR WERNIG's instructions, published in THE GARDEN from time to time, in reference to drying flowers and Grasses, have so much pleased me that I am induced to ask a few questions respecting the preservation of white flowers. In some cases I have succeeded very well with these; but, in others, I have failed. The floral leaves or, rather, petals soon curl and turn yellow, especially those of Roses, when dried in sand. Is there any chemical agent which could be used to bleach them after being dried? By what process can I pre-

serve white Camellias, Tuberoses, Pinks, Roses, &c., so that they will retain their original whiteness and form? I have failed to dry white Camellias without being spotted. In drying the Immortelle with borax ought the flowers to be bleached first, or remain in their natural yellow colour?—L. F. SANDERSON, River Bank Nursery, San José, California.

[To the foregoing Mr. Gustave Wernig, to whom this letter has been sent, furnishes the following reply:—If Mrs. Sanderson did not succeed in preserving white Camellias, white Roses, Tuberoses, and similar flowers, she has not had a worse result than the most experienced preservers of flowers have. Up to this time I do not know a single instance in which I have seen a dried specimen of the above-mentioned flowers, and of many others—as, for instance, all the Orchids, and most flowers of Monocotyledonous plants. White flowers, especially, are very difficult to manage, as they nearly always become spotted with a shade of yellow, which gives them a rather dirty appearance. The only flowers which are pure white in bouquets of Everlastings are to be found amongst the true Everlastings, viz., the pretty little *Anemobium alatum*, white Immortelles, *Xeranthemum annuum album*, &c. How to preserve these well I described in my former articles. Even among dried white Asters, although much used and, if well done, pretty looking, I never could

find one which was pure white; every one had, more or less, a shade of yellow. It may be that, with the aid of chemistry by-and-bye, we may succeed in preserving a greater number of flowers in their natural colours; but, up till now, we must be contented with a limited number. Referring to the other question in the above letter about the colouring with borax, Mrs. Sanderson may, without hesitation, take the Immortelles in their natural state; yellow as they are, they turn to a beautiful scarlet if managed in accordance with the directions which I gave in a former number of the *THE GARDEN*. I must add, however, that flowers coloured with borax become paler in the course of time, especially if exposed to the sun; while those coloured by aniline keep their colour much longer. Borax, however, is cheaper and gives the finest scarlet.]

THE FRUIT GARDEN.

CAUSES OF THE EXHAUSTION OF FRUIT TREES.

By P. T. QUINN.

THE failure of certain varieties of fruit to bear maximum crops of well developed specimens every year, or even every alternate season, under what would be acknowledged as high culture, does not always prove that such a variety is worthless and should be placed among the rejected fruits, for, with similar treatment, this same variety, grown upon a different quality of soil in another locality, might yield abundantly of full-sized fruit, recommending itself by its natural thrift and productiveness. Failures arising from uncongeniality of soil and climate, are striking in every district where fruit growing has been attempted in this country. At this time, among the more intelligent cultivators, it is very generally accepted, both in practice and theory, that there are comparatively few varieties of our multiplicity of kinds that can, with any prospect of ultimate success, be recommended for orchard planting beyond the boundaries of single States, nor is it rare to find instances where different sections of the same State, call for entirely different lists of fruits, owing solely to the causes named. I mention these facts here, and lay particular stress upon them, in this brief paper, for I am well aware of the fact, that there is nothing more conducive to neglect and ill-usage in the management of a fruit orchard, than to begin with a lot of varieties unsuited to the locality. Therefore, while tracing the causes of "exhaustion of fruit trees," it may be well to warn beginners from taking a wrong step at the start, and one so prolific of bad results that is so likely to mar the path of the inexperienced fruit culturist. Choose the list of varieties then after full deliberation and thorough canvassing of the subject, and let this care and caution govern every step taken, not only in selecting lists of kinds, but also, from whom such trees should be purchased, for at this critical period there are two more important considerations that will need earnest attention. The first, is to be sure and get strong and well-grown trees, and secondly, that such are true to name. To start with poorly-grown stock, is courting disease and disappointment on the threshold of an undertaking, and to have fruit trees turn out untrue to name, is one of the most discouraging events that the beginner has in store for him, for it will prove as expensive as distasteful, bringing pangs of regret, too late, however, to remedy. Both of these may easily be avoided, and at no extra cost, by ordering the trees from some responsible nurseryman who has his reputation at stake, for such are always quite as anxious to send out good stock and that true to name as the inexperienced purchaser is to be sure of these two points at starting. In treating the subject of "exhaustion of fruit trees," from a practical stand-point, the old and familiar adage comes into play, that an "ounce of prevention is better than a pound of cure," for trifling mistakes made at starting very often lead to disastrous results. Before planting Corn, Potatoes, or Onions, successful growers are sure to make a careful survey of the condition and quality of the soil, adding what it may lack before depositing the seed, for to the wise it is self-evident unless these are up to the standard, the profits will be small. And so it is with the market gardener, who raises two and sometimes three crops from the same ground the same year, and this year after year for a lifetime, without exhaustion of the soil, but, on the contrary, improving it each year. But the gardener knows full well, without being told, that if he raises two crops from the same ground in a year, he has to manure for two, for if not, it is time and money thrown away, and better by far to only attempt one instead of two. If persons, in starting a young orchard, would always follow the market gardener's rule, the end would justify the means, and instead of a meagre supply of fertilising material for one crop, there should be a liberal allowance given for two; in due time the trees would reimburse threefold for the outlay. But how very seldom we find this carried out in orchard practice. With a

young orchard of Apples or Pears, no returns in the way of fruit are expected for six or seven years, and in the meantime the ground is cropped as usual, to pay expenses, using just enough of manure to bring the cultivated crop to maturity, forgetting or overlooking the fact that there are two crops on the same ground, each having needs, while only enough of manure is applied for one. By this short-sighted economy the trees are pinched, their growth and vigour impaired, and, in thousands of instances, the orchard permanently injured, leaving what fruit such trees produce at the mercy of the insects that now-a-days infests our orchards. Even when the ground is in good condition and fertile at the time of planting, following a plan similar to the one described, the results cannot be otherwise than fatal to the health and productiveness of such trees. Although the bad effect of such treatment may not show itself in so short a time, as when orchards of Apples or Pears are sown in cereals or Grass, still it tells against the trees in the long run. In Pear culture, exhaustion and premature death of certain varieties is hastened by neglect in furnishing the soil with fertilising material and allowing young trees to overbear. This latter practice has, in my belief, permanently injured more Pear trees than all the other causes combined, and cannot be too strongly condemned or denounced, for whenever encouraged it is sure to prove fatal. In my planting of the Pear in the future, I will not allow a Pear to grow on a tree, no matter how vigorous it may be, until the tree is at least five or six years in place. Under good treatment, by this time the trees will be of good size, the roots well established, and the tops strong and capable of carrying a crop without running any risk of injuring the trees. I know from experience that this is by far the best plan to follow.

Another and very productive source of exhaustion is in planting fruit trees too far apart. When Apple trees, for instance, are set 40 feet apart each way, and Pear trees 25 feet, there are wide intervening spaces between the trees, that under the most favourable auspices of high culture it will take, at least, a quarter of a century for the trees to shade and occupy the whole of the ground. Five or six years from the time of planting such an orchard, the old custom was, and, by the way, it is very common even now, to sow the orchard down to Grass, and keep this part of the farm in permanent meadow. In open ground, meadows are seldom left longer than four or five years without breaking up the sod, cropping for two or three years, and again re-seeding. But, owing to the inconvenience of ploughing among trees, and the uncertainty of getting hoed crops to grow in the shade of such, the sod in the orchard is left unbroken five, ten, and twenty years. In these long terms, the more nutritious and better quality of Grasses are gradually run out, and replaced by the more vigorous and inferior native sorts, much more formidable rivals in the contest for food than the former occupants—a fact that tells its own story from year to year in the starved appearance and unfruitfulness of such trees. However, the crop of hay is cut annually, and the Apples gathered and taken away, while there is nothing returned in the shape of manure to make up, in whole or in part, for this annual drain upon the soil. Within my own compass, I know of dozens of Apple orchards that have been kept constantly in Grass from twelve to twenty years, the Grass cut, and Apples gathered (when there were any to gather), and to my knowledge there has not, within any five years, been enough manure applied to raise one crop of Potatoes, nor, during that time, as much labour given to the trees as would be in raising a single crop of corn. Yet these very men who are excellent grain farmers, will wonder why it is that Apples don't grow and bear as they formerly did when they were boys, and that there is no use in trying any more. Grass is bad enough, under the best treatment, in an orchard where manure is applied to the surface in liberal doses at regular intervals; but when this part is neglected, or overlooked for a term of years, it will need no prophetic vision to foresee the final result. Meagre crops of very indifferent fruit will be the sum total of such treatment. That there are certain old favourite sorts of fruit that grew vigorously and bore abundantly, in the first half of the present century in many localities, but of late years, owing to climatic causes, have hopelessly failed under the best culture, none can dispute. But in the meantime, others, and equally valuable kinds, have taken their places, kinds that respond freely to high culture and are fully up to the standard in quality. These cases of failure are confined to a limited number of kinds, and do not, as many suppose, affect the whole list of sorts. To make fruit culture pay the highest profit, I am thoroughly convinced of the importance of close planting, and low heading, so that when they reach the bearing age, the ground will be exclusively given up to the trees. Manure should be applied regularly, and the surface kept under the plough, running this implement, among bearing trees, not deeper than 2 or 3 inches.—*Proceedings of the American Pomological Society.*

THE GARDENS OF ENGLAND.

BURGHLEY GARDENS, NEAR STAMFORD.

BURGHLEY House, one of the finest examples of the Elizabethan style of building extant, is a stately pile irrespective of its historical interest, and the well-known romantic associations with which it was invested by one of the later Cecils. Impositing mansions are, however, easily created, or, according to Lord Bacon, "men come to build stately, rather than to garden finely." I will, therefore, direct attention on this occasion more particularly to the noble and widely-spread park, the fine trees which it contains, and to the useful fruits and vegetables with which the fruit and kitchen gardens are stocked, than to technicalities of architecture. The park consists of some 1,500 acres, from the more elevated positions of which, some extensive and beautiful views are obtained of the town of Stamford, and of the well-wooded country beyond it. There are, strictly speaking, three parks, all well-planted; the lower one being diversified by a large sheet of water, which stretches away like a broad river immediately in front of the mansion. Here, as elsewhere, are some noble trees—Oaks, Elms, and Chestnuts, while here and there the striking foliage of the Purple Beech stands out conspicuously, backed by the lighter foliage of Maples and Limes. There are also a few stately Cedars which throw their sombre-tinted branches over the turf in every direction. Hawthorns are plentiful, and, by the abundance of fruit which they are producing, some idea may be gleaned as to how attractive they must have been early in the season when covered with snowy flowers. Chestnuts form a great feature here, and some fine glossy-leaved Oaks are remarkable for their size and vigour. The High Park, as it is called, is an agreeably undulated piece of ground of considerable extent, well stocked with deer. Here, also, are some fine avenues of Limes, whose leafy interlacing branches form a perfect Gothic canopy overhead. These are always beautiful; but, when seen under golden sunlight or silvery moonbeams, and when strong light and shadow throw the perspective into bold relief, then is the time to see the avenues at Burghley at their best. Broad patches of Fern afford shelter for the dappled deer, which are seemingly unconfined, owing to the care with which all boundary lines have been hidden from view. Scattered here and there over the park are some picturesque thatch-roofed cottages, overrun with climbing Roses and Clematises, the effect of which is excellent. The fruit gardens are fully a mile from the mansion; they are situated at the extremity of the High Park, and are, for the most part, surrounded by a sunk fence. Inside are parallel walls, against which the fruit-houses are erected—all lean-to structures, heated by a pair of Weeks's tubular boilers, set side by side.

The Vineries.

I have seen these houses—some half-dozen in number—before, on several occasions, but never saw them look better than at present. Anyone seeing them and noting the unusually heavy crops which the Vines are bearing, would be sure to predict their becoming worn out at no very distant date. This is, however, far from being the case, and, in point of fact, they are not in the least overworked, although they would certainly appear to be so to ordinary cultivators, who seldom take more than eight to twelve bunches from a Vine. Mr. Gilbert's theory is "plenty to eat and plenty to do," and it is a system to be recommended, judging from the results realised at Burghley. A house of Hamburgs here, any enthusiastic Grape grower would go miles to see; the clusters are not only large and numerous, but every berry has an oblate or flat-ended form, a sure sign that they are well fed. These are colouring finely, and will succeed the Grapes now being cut from pot Vines. A Vine of Ferdinand de Lesseps, a seedling raised by Mr. Pearson, of Chilwell, with a fine musky flavour, is here doing better than I have ever seen it elsewhere. It is grafted on a black Hamburg stock, and is bearing about a dozen clusters, the largest weighing fully three quarters of a pound. When well grown, as at Burghley, this is a most desirable Grape, being quite distinct in flavour from all other kinds, and very early. The Vine borders at Burghley are all mulched with well rotted manure, and some idea of the way

in which the Vines are fed may be gleaned from the fact that only a day or two before my visit Mr. Gilbert had poured nearly 4,000 gallons of water on one of these borders alone, a saturation which washed down the nutriment from the mulching to the roots. Failures in fruit culture occur more from want of water than from any other cause, and though drought is most to be feared in the case of Peaches, Nectarines, and other fruits planted in inside borders, yet even Vines planted in outside borders are greatly benefited by copious waterings all through the hottest and dryest months of the year. One thing in particular struck me in regard to all the Vineries at Burghley, and that was not only the abundance of fruit which they contained, but what is of more than equal importance, stout short-jointed canes and fine fresh green foliage in abundance, a sure proof that the roots are in a suitable medium. Some of the leaves on the Black Hamburgs measured from a foot to 15 inches in length, and quite as much in breadth; and, notwithstanding the dry season, I did not see a trace of red-spider. About twelve months ago, Mr. Gilbert planted a house of late-keeping Grapes, such as Gros Colman, Waltham Cross, Seaclyffe Black, and others, including some Vines of Trebbiano, a kind which, at Burghley, is found to be one of the finest and most valuable of all late-keeping Grapes. To have it in its best condition, however, it must be perfectly finished off, *i.e.*, thoroughly ripened, otherwise it scarcely reaches mediocrity, a remark which equally applies, to Gros Guillaume or Barbarossa, as it is commonly called, although when well-ripened under sun-heat it is one of the best of late kinds. These young Vines, although so recently planted, cover the roof, and have made fine stout growth as thick as one's thumb. The foliage is also large and fine, the shoots being trained out in such a way as to give to the foliage its full share of light, sun, and air. Pot Vines have been excellent here this spring, and there are many fine bunches fully a pound weight each still to cut from them. The secret of Mr. Gilbert's success with pot Vines lies in inducing an early and vigorous growth, so that they may have plenty of time to ripen off their wood in autumn, whereby the canes get thoroughly ripened. Genial heat, good turfy loam, and plenty of good feeding in the shape of manure-water will do the rest. We have already alluded (see p. 333, Vol. IV.) to Mr. Gilbert's excellent method of growing Vines in pots for the decoration of the dinner-table, and need only now add that this season they have been as good as ever. Among pot Vines we found the new seedling, named Gilbert's Russian Emperor, which promises to be a useful black Grape for early work, a desideratum in the case of those who have to put Grapes on their employer's table every day in the year. The Vine in question, though a weakly one, has produced thirteen fine bunches this season. The latter are long and tapering, the berries being quite distinct in shape from those of the Black Hamburg, being oblate and slightly flattened at both ends, and the flesh is well flavoured and juicy. Two houses of Muscats are full of handsome clusters, varying from 1 to 3 pounds weight each. The foliage here, as elsewhere, is large and fine.

Other Fruit Houses.

Early Melons, now over, have been excellent. Mr. Gilbert is noted, not only as a good grower of Melons, but as a raiser of them, his last Hybrid Greenflesh, Lady Isabella Cecil, being one of the best in its class. Gilbert's Greenflesh is also a fine oblong deep golden fruit, beautifully netted, and possesses a fine flavour. Victory of Bath is now too well known as one of the best of Melons, either for show or table, to need any comment; this is largely grown at Burghley, where both it and Lady Isabella Cecil are great favourites. Of Pine Apples, I saw in the fruit-room some Queens which weighed from 3 pounds to over 4 pounds each; and, in addition to other fruiting and succession plants, Mr. Gilbert has just planted one pit with the newer varieties, including Thoresby Queen, a fine plump fruit (its only drawback being its small crown), and Charlotte Rothschild, one of the finest Pines grown. Smooth-leaved Cayennes and Black Jamaicas are also grown for the sake of variety. An extensive addition to the fruit-houses is about to be made in the shape of a Cherry-house, 64 feet long; and another house is to be built for Figs. In addition to these, a grand tropical fruit-house is in contemplation. When these are

built, Burghley will be one of the most extensive and complete fruit-growing establishments in the country. Strawberries in pots are nearly over, but have been very fine this season; and in one of the Pine-pits I noticed some fine Tomatoes, grown in pots with the view of ensuring a supply all through the winter and early spring, after the outdoor crop is finished. Peaches do not succeed well on open walls at Burghley; therefore, the main supply of this fruit is obtained from trees under glass. Outside, the trees suffer severely from fly and blight, although repeatedly syringed and dusted with Tobacco. There is, however, a fair sprinkling of fruit on most of them. Inside the houses, the Peach trees are in perfect health, and some trees of Royal George are bearing a splendid crop of fine fruit. In a late house of Peaches and Nectarines, the trees, planted three years ago, already cover the roof with fine wood and fresh healthy foliage. These will be invaluable as regards supplying a succession of fine fruit until late in the season.

Hardy Fruits.

This promises to be an excellent year for all kinds of out-door fruits, with the exception of Peaches, which, as previously explained, are rather thin and poor—a circumstance with which the absence of rain has doubtless much to do. Cherries, especially Morellos, on north walls are a full crop, and the trees are very healthy. I was also glad to note that there is a fair sprinkling of fruit on the Burghley Park Cherry, a variety which owes its notoriety to Mr. Gilbert's good culture. Gooseberries and Currants are laden with fine fruit, and Strawberries are also abundant. Ingram's, or the Five-leaved Pine, is much grown here, and is esteemed for its excellent colour and fine flavour. Black Prince is still one of the earliest of all Strawberries, either for out or indoor culture, its only fault being its small size. The old Grove End Scarlet is still grown here for preserving—a purpose for which it is well suited. Raspberries are trained on the arch system, a supporting upright stake being placed in the centre of each arch; and, thus managed, they bear fine crops of fruit. Prince of Wales, Mr. Gilbert says, is the best variety he has, and one which deserves to be better known than it is. Apples and Pears promise to be fair crops; and Apricots look remarkably well, the foliage being fresh and clean, and there is abundance of fruit.

The Kitchen Garden.

This is very extensive and well stocked with vegetables, in the culture of which Mr. Gilbert follows the market garden system, in which heavy manuring, deep trenching, mulching, and copious waterings play important parts. Peas are producing wonderfully fine crops, which, however, have to be closely netted in order to protect them from jackdaws, which, notwithstanding a liberal use of cartridges, are found to be very destructive. Among new varieties, Mr. Gilbert is very fond of Fillbasket, one of Mr. Laxton's latest novelties, and one which promises to be a profuse cropper; it grows about 3 feet high, and bears full-sized pods, each containing from eight to nine Peas, very sweet, and of a beautiful fresh green colour. Standard is another good dwarf Pea, although hardly so profuse a bearer as the last. William the First is one of the newer early varieties; it grows about 3 feet high and produces satisfactorily. This is a favourite, as is also another novelty named Surplanter, a dwarf variety, very sweet and good. Cauliflowers are better than might have been expected, considering the late dry weather. This year, Mr. Gilbert has tried a new plan in regard to Cauliflower culture; he plants them in a trench which has, as a matter of course, been well manured; treated in this manner, three rows being put into a broad trench slightly below the ground level, they succeed admirably. Potatoes look well; Mr. Gilbert covers the young growth with dry Fern, a plan much to be recommended in unfavourable seasons; Johnson's Premier is found to be one of the best of the early sorts, and Myatt's Ashtop, Early Handsworth, and other early varieties, are also largely grown. These are planted 3 feet apart, each way, and a mixture of sand and lime added to the ordinary soil suits them admirably, the tubers turning out clean and fresh. Mushrooms in open air beds have been very plentiful, over a bushel being, sometimes, gathered in one day, notwithstanding the late dry weather.

F. W. BURBIDGE.

THE ARBORETUM.

THE CONIFERS OF ITALY.

In all representations of Italian scenery the Stone Pine (*Pinus Pinea*) forms a conspicuous object, and it was no doubt as common in the time of the Romans as at present. Ovid describes this tree as having erect foliage, or a bristling head; Pliny says that it is branching at its top, whilst *Pinaster* is so from the middle of its trunk upwards, and that it bears at the same time fruits about to ripen, others which will ripen the next year, and others, again, which will ripen the third year. He also says it has a very large fruit, and it is, in fact, that which, among the Italian species, bears the largest cones. He says that the nuts are found in cavities, and are covered with a layer of rust, by which they are enabled to lie softly; he states, moreover, that the seeds are eatable, which is only true of this species and of *Pinus Cembra* of the Alps. The Pine was then, as now, cultivated in gardens, and Virgil calls it their most beautiful ornament; Horace, too, mentions a Pine that grew near his country house; and, according to Varro, Pines served to mark the boundaries of estates. Lastly, in Pompeii and Herculaneum, we find figures of Pine cones in drawings of fruits and of culinary substances, and also on the arabesques; in Herculaneum kernels of charred Pines have been discovered. The *Pinaster* of the ancients does not appear to be the same as that of the moderns; the former was said to be of extraordinary height, whilst the latter is almost as low as the Stone Pine. For the same reason the *Pinaster* cannot be the common *P. halepensis*, which is still lower than the Stone Pine. But this great height agrees with the *P. Laricio*, which in Corsica attains the enormous height of 140 or 150 feet, and in Sila, in Calabria, of 120 to 130 feet; but the statement that the *Pinaster* grew in the plains does not apply so well, for *P. Laricio* is a mountain tree; but Tenore says that it is occasionally found in the plains. By *Pinaster*, Pliny probably meant both *P. Pinaster* and *Laricio*, which are not very unlike one another. Pliny's *Pinaster* cannot possibly be *P. sylvestris*, for the latter is found on the Alps only at a certain height above the sea, and rarely perhaps on the northern Apennines; it is not very high.

Firs are distinguished by Pliny, and other Roman writers, into two sorts, *Abies* and *Picea*; two sorts are also found in Italy at the present day, viz., the Spruce Fir, which only occurs on the Alps, and the Silver Fir, properly so called, which is spread over the Alps and the entire chain of the Apennines. We may, therefore, look upon the *Abies* of the Romans as our Silver, and their *Picea* as our Spruce Fir. The Larch of the Romans may be looked upon as identical with our Larch. This tree was found nowhere in Italy but on the Alps. Pliny's remark, that the Larch grows in the same places as the Spruce Fir, confirms this. He also says that at Rome, a bridge, over a place where sea-fights were represented, had been burnt, and that the Emperor Tiberius ordered Larches to be felled in Rhetia, *i.e.*, in the Alps, to repair it. He afterwards notices the greatest tree that had been seen in Rome at his time; it was exhibited as a curiosity by Tiberius on this same bridge: it was kept till the building of Nero's amphitheatre; it was a trunk of a Larch 120 feet long and 2 feet thick. The localities in which the Cypress is found in Italy show that it is exotic. Pliny says that it was a foreign tree, brought from Crete, and difficult to cultivate. According to Theophrastus, the pyramidal variety of the Cypress grows in Crete, on the top of Mount Ida and the White Mountains, which are covered with eternal snow, a singular circumstance, since elsewhere it only prospers in warm countries. Near Somma, in Lombardy, there is a Cypress, which Napoleon respected when he constructed the Simplon. It is 121 feet high and 23 feet in circumference at 1 foot above the ground. This, diameter, when the very slow rate of growth of such trees is remembered, proves it to be very old. The Abbé Belèse says that, according to ancient records, this tree existed in the time of Julius Caesar, *i.e.*, half-a-century B.C. Pliny mentions a Cypress at Rome that was thought to be as old as the city itself, and which fell in the reign of Nero. At any rate, it is certain that the cultivation of the Cypress was known in very early times. Cato and Varro say that it was

ITALIAN CYPRESS PINUS PINEA AND THE ITALIAN CYPRESS.

planted in gardens to mark their limits. The Juniper of the ancients is the same as that of the moderns; of this there is no doubt. Ancient writers describe it as having spines instead of leaves, and as keeping its fruits all the year round, and sometimes those of the preceding year. The Juniper is said to have no flowers, and, by mistake, it has been supposed that there are two sorts—one with flowers and the other with fruits; this refers perhaps to the two sexes, which in this plant are on different individuals. The *Taxus* of the ancients is no doubt the same as our present Yew tree. Pliny mentions it at the end of his enumeration of the Conifers, and says that it resembles them; that it is the only one with berries; that it is dark, graceful, sad-looking, and without resin. In another passage, he says expressly that it is an evergreen. It was generally believed in ancient times that the Yew was poisonous. The frequent mention of the Yew by the ancients leads us to suppose that in their time as well as in our own, it grew both on the Apennines and on the Alps. The art of clipping trees and giving them all sorts of shapes was known to the Romans; but, although this was done with the Cypress, the Silver Fir, and the Box, it was not practised on the Yew, probably because the latter tree required a colder climate than the plains afforded.

There is no reason for supposing that the species of Conifers indigenous in Italy at the present time differ from those of former ages. The most common and the most easily distinguished are expressly mentioned by ancient authors, and are, for the most part, described with sufficient accuracy to enable us to determine what they really were. Those that are not mentioned may, from the vague ideas of those times, be considered as having been united to the others, or as having altogether escaped observation. Although Italy contains twenty species of Conifers (excluding the Cypress), and Europe north of the Alps has but six, the number of individual trees is by no means apportioned in the same way. The Conifers in the north of Europe form immense forests, and consequently play an important part in the general aspect of the country. In Italy, on the contrary, with the exception of the Alps, where they form by their quantity a region at the mean height, these trees constitute but small scattered woods, which give no important feature to the landscape. Along the coast of the Gulf of Genoa, as far as the Roman States, some forests of Pines peculiar to the basin of the Mediterranean are certainly found—*Pinus Pinea*, *Pinaster*, and *halepensis*; the coppices near the coast contain Junipers of the south of Europe; Spruce exist in some countries of the central Apennines—for example, near Vallambrosa and Camaldoli, and generally in the upper part of Tuscany. Forests of Conifers are also met with in the Abruzzi, and on Mount Sila, in Calabria, where the Silver Fir or the Calabrian or the Corsican Pine predominate. On Etna, lastly, forests of the Corsican Pine exist; but the whole is not to be compared with the immense tracts covered by these trees in the north of Europe. It appears, then, that Italy is not very largely stocked with Conifers, and they consequently play a subordinate part in the operations of life. In the Alps exclusively do we find these trees the objects of the same industry as in the north; here they are cut down, slid over the sides of the mountains, floated down the rivers, divided in saw-mills, and sent away as trunks, beams, and planks; this work, too, is only found going on here and there, and on a comparatively small scale. In Scandinavia and northern Russia the houses are constructed almost entirely of the wood of Conifers; in central Europe this wood is also largely used for beams, floors, and staircases; in Italy, with the exception of the Alps, the houses with the staircases and floors are built of nothing but stone or brick. In the north Conifers are used for palisades, bridges, and roads; in the centre of Europe they are greatly employed for bridges, partitions, and garden palisades; but in Italy the bridges are of stone, and high walls surround the gardens. The wooden pipes for water and the piles of the north are replaced in Italy by stone aqueducts and piers. As Italy, with the exception of the Alps has but few mines, she does not, like the north, employ large quantities of Fir-wood. Genoa obtains planks for her ships from the western Alps and from Corsica; Venice and Trieste theirs from the eastern Alps; Naples has hers from Sila; Italy, however, imports pitch, tar, and other

resinous products from foreign countries; but Venice is the principal place of exportation of one of these products—Venice turpentine, which is obtained from the Larch on the high regions of the Alps. On the south slope of the Alps turpentine is also obtained from the two species of Fir; it is collected by the Italian peasants, who ascend the mountains and climb up the trees to make incisions in them. During the middle ages the Yew was very much destroyed in consequence of the great commerce made by the Venetians of its wood; for, before the discovery of powder, the Yew was in high esteem for making bows. In former times the Yew was much more common to the north of the Alps than at present.

Pinus.

P. Pinea (the Stone Pine).—This is found on the sandy coasts and hills of Tuscany, to the west of the Apennines, and on the hills of Genoa, usually accompanied by, and frequently forming forests with, the *Pinus Pinaster*. The large forest near Ravenna is, according to Bertolini, formed of this Pine; it is also found in the country about Nice. It is generally cultivated throughout the whole of Italy, from the foot of the Alps to Sicily. It is not commonly found higher than from 1,000 to 1,500 feet, but it occurs in the south of Italy as high as 2,000 feet. It is found, according to Sibthorp, on the sandy coasts of the Western Peloponnesus, in the same conditions, probably, as in the middle of Italy; it is also met with in the island of Meleda. Cultivated, it is found on all the shores of the Mediterranean.

P. sylvestris.—This tree occurs frequently in Italy on the southern slope of the Alps, from Friaul to Nice (as, for example, in the valleys of Tagliamento, Piave, on the Baldo and Legnone Mountains, in the Valteline, on the Simplon, Mont Cenis, and at the Col de Tende), especially in the sandy soil of the valleys; it is not, however, as abundant as the Spruce, Silver, or Larch Firs. As a general rule, it cannot be said to exist lower than 2,000 feet above the sea.

P. Pumilio.—This is found on the southern slope of the Alps, towards the east as well as towards the west; but the transitory forms of *Pinus sylvestris* are so common, and the distinctions between them and *P. Pumilio* so narrow when there are no cones, that I am not quite certain that some of the localities given for this do not belong to Alpine forms of *P. sylvestris*. *P. Pumilio* is found beyond the limits of trees; but scarcely higher than 7,500 feet, nor lower than 4,000 feet. It prefers a swampy soil. This species also grows on the northern slope of the Alps, and is very common on the Carpathians, where it forms a region above that of the Spruce Fir between 4,100 and 5,600 feet.

P. Laricio.—This species (the Corsican Pine) is very common on Mount Etna, where it forms woods at a height of from 4,000 to 6,000 feet. It also forms forests, according to Tenore, on the mountain of Sila, in Calabria. It was first discovered in Corsica; but it has since been found in the countries of the south of Europe; for example, on Mount Serrat, in Spain; on Mount Athos, on the Taygetus, Cyllene, and other mountains of Greece, as well as on Mount Ida in Crete, and in Phrygia.

P. Pinaster.—This species grows in the sandy plains, and on the lower mountains, on the south slope of the northern, and on the western slope of the central, Apennines. It is not found to the south of these mountains, nor before we come to the north of the Apennines.

P. halepensis.—This species is not found to the north of the Apennines; but it is very common to the east and west of these mountains, as well as in Sicily. It grows on sand and on rocks, but best on the latter; its upper limit is 2,000 feet at the outside (the Somma between Terni and Spoleto).

P. brutia.—The Calabrian Pine approaches, rather too near perhaps, *P. halepensis*; but its cones are nearly sessile, the tops of their scales rough, and its leaves are longer than those of *P. halepensis*. It grows, according to Tenore, in Calabria, especially on the Aspromonte, at a height varying from 2,100 to 3,600 feet.

P. Cembra.—This is found in the high regions of the Alps, from the Tyrol to Mont Cenis, but scattered between 4,000 and 6,500 feet. It is also found on the northern slope of the Alps, from Austria to Savoy and Dauphiné. It occurs also in the Carpathian mountains and on the Altai.

Abies.

A. excelsa.—The Spruce Fir is very common, and forms forests on the Alps from east to west. It is principally found at a height varying from 4,000 to 6,500 feet. It is found on the Engadine hills, but nowhere on the Apennines. According to Bentham it occurs on the Pyrenees; but it does not grow even on the mountains in the countries surrounding the Mediterranean. The tree found in the

north of Asia, which is somewhat analogous to *A. excelsa*, is a different species (*Picea obovata*).

A. pectinata (The Silver Fir).—This is found all over the Alps from east to west. It is principally found at a height of from 2,000 to 4,000 feet, but it occurs as low as 1,000 and as high as 4,500 feet. Like the last species, it is found on the Euganeans. It grows on the whole chain of the Apennines from north to south.

Larix.

L. europæa.—The Larch is spread over, and forms forests in, the upper regions of the Alps, from east to west. Its proper region is at a height of from 3,000 to 6,500 feet; it sometimes occurs as high as 7,000 feet, but it is then dwarf, and occasionally as low as 2,000 or even 1,500 feet (near La Piave). It is not found anywhere on the Apennines. The Siberian Larch is, according to Ledebour, another species (*Larix sibirica*).

Cupressus.

C. sempervirens.—The Cypress is found in gardens, or cemeteries, or avenues, throughout the whole of Italy, from the foot of the Alps to Calabria, as well as in Sicily; it is here and there found wild. The upper mean height at which it grows is about 2,000 or 2,500 feet. It is very common in the other countries surrounding the Mediterranean, Greece, Barbary, Africa, &c. It is supposed to be really wild in the Grecian Archipelago and in Asia Minor.

Juniperus.

J. communis.—The common Juniper occurs very generally on the Alps from east to west, from the foot to a height of 5,000 feet. It grows in a dry sandy soil, on heaths and in woods. It occurs in the whole of the north of Europe as far as Lapland. It is also found on the Pyrenees, in Spain, and in Greece, but, as it seems, only on the mountains, and, lastly, in the Caucasus.

J. nana.—This is found on the Alps, in the sub-Alpine and Alpine regions, seldom below 5,000 or above 7,500 feet, and on the Apennines. To the north of the Alps it occurs on the Carpathian mountains.

J. hemisphærica.—This is found in the upper barren region of Mount Etna, low and spreading. Its region may be fixed between 5,000 and 7,000 feet. Tenore says that it was found by Gussone on the Aspromonte, and on several of the mountains of Calabria.

J. oxycedrus.—This species is quite different from *J. macrocarpa*, with which it is often confounded. It is found on the Apennines, at a height of from 1,000 to 3,000 feet.

J. macrocarpa.—This is found on the sandy coasts and rocks of the Mediterranean, the Adriatic, and in Sicily. It occurs, too, in Greece, near Cadiz, and is probably spread over all the coasts of the Mediterranean.

J. Sabina.—The Savin is found on the Alps and on the Apennines. Some Italian botanists say that it grows on rocks near the sea; but, probably, this was *J. phœnicea*. According to Bentham, it grows on the Pyrenees.

J. phœnicea.—This is found on rocks on the shores of the Mediterranean, from Nice and Oneglia to Calabria, and in Sicily; and also along the Ionian Sea and the Adriatic, from Tarentum and Gallipoli to Cherso. It is generally spread round the Mediterranean, in Greece, and its Archipelago, probably, also in the Levant.

Taxus.

T. baccata.—The Yew is occasionally found on the Alps, the mountains of Piedmont on the Apennines; it is probably not wild in the plains. Its lower limits are 1,000 feet on the Alps, and 2,000 feet on the Central Apennines; its upper limit reaches the region of the Conifers, and that of the Ash in the Apennines. It is found on the western and northern slopes of the Alps, in the mountains of Central Europe, in Scotland, and in the Scandinavian Peninsula.

[The above particulars are abstracted from Professor Schouw's paper, published in the Journal of the Royal Horticultural Society.]

The Large Beech Tree at Newbattle Abbey.—At a late meeting of the Botanical Society of Edinburgh, Sir Robert Christison gave a short notice of this remarkable tree. The trunk rises about 20 feet before giving off branches, and it then rises with a certain methodical irregularity, carrying a great girth to a great height. It is difficult to describe this upper trunk. The branches appear rather to form the trunk than to rise out of it, constituting as it were a part of the trunk some way up before taking their outward course as true branches. The extreme branches are everywhere covered with fine twigs, showing that the whole tree is healthy and thriving. During a late hurricane a huge limb was snapped off, but there are

so many more that its loss is scarcely noticed. At 2 feet from the ground the buttresses make the girth 32 feet; at 5 feet it is 21 feet; and at 7 feet, the narrowest part below the first branch, it is 18 feet in girth. The great massiveness and height of the trunk, produce a sort of oppression on the inner sense of the spectator. On the whole it is more gigantic than the Eccles Beech, chiefly, perhaps, on account of the much greater length of trunk before its first branches come off. It is undoubtedly taller, and in every way an object well worth going a long distance to visit.

Cytisus Laburnum serotinum.—Some time since, M. Carrière, in the *Revue Horticole*, drew attention to this variety of Laburnum, which he described as a remarkably handsome shrub, with unequal leaflets, frequently smaller than those of the common Laburnum, and slightly turned up at the edges. The flowers are of a fine yellow colour, very numerous, and disposed in compact clusters. They do not begin to appear until some time after the common kind has burst into bloom, and they last for some time longer; hence the specific name "*serotinum*." M. Carrière remarks that this variety is sometimes confounded with *C. L. trilobum* or *longiracemosum*, but the latter flowers earlier, and its clusters of flowers are much longer in shape and fewer in number. *C. L. serotinum* has the rare merit (as a shrub) of being a suitable and ornamental subject for flower-beds, as, no matter how much it may be cut back, or how dwarf it may be trained, it always produces a profusion of flowers.

Demand for Seeds of Famous Trees.—The demand for the seeds of the Sequoia (*Wellingtonia*) gigantea and the Eucalyptus globulus, is unprecedented. Half a million trees of the latter were sold last season in this vicinity; and nurserymen predict that the demand the ensuing season will extend to three million trees. A very large number of the other sorts of Gum trees are sold for ornamental purposes, many of them being more desirable for such purposes than the Blue Gum. There are twenty-seven varieties of the Australian Gum tree grown in this vicinity. Some of them are equal, in every quality which constitutes a good shade-tree, to any tree grown on the Pacific Coast. The seed of the Blue Gum is now retailing for about three dollars an ounce. There are about three thousand seeds in an ounce. The seed of the Sequoia gigantea retails for about the same price; and the demand at present is ahead of the supply. It is now sent all over the world. But the demand is the greatest from Australia. There is also a good demand for the seed of the Monterey Cypress. For hedges and wind-breakers nothing has yet been found in this country equal to this species of Cypress. If the tree is left to grow in its natural state it makes wood as fast as the Blue Gum.—*San Francisco Bulletin*.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Coning of Araucaria imbricata.—Much has been said of late in gardening papers about this Araucaria producing cones. Our tree, which grows near the suspension bridge in the grounds here, had several cones on it last year; but I was unable to get any seed. This year it has about thirty cones on it; I therefore hope to be more fortunate.—T. CLEMENTS, *Pain's Hill, Surrey*.

Singular Effect of Eating the Berries of Rhamnus crocea.—A Transatlantic naturalist says that the red berries of this Buckthorn, which the Apache Indians eat, have a curious property. The colouring matter is taken up by the circulation, and diffused through the system, so that "the skin exhibits a beautiful red net-work."

Where can Ruscus androgynus be obtained?—Can "J. H. Q." (see p. 517, Vol. V.) tell me where I may procure this? It is a plant I have been seeking for during these last twenty years; but have never seen it offered for sale or named in any catalogue. When at Bilton gardens last summer, I noticed a thriving specimen of it out of doors, trained against the wall of the residence; Mr. Ellacombe, while courteously showing me his fine collection of herbaceous plants, told me that he obtained it from Madeira. At the same place, if I mistake not, I saw a nice tuft of *Cypripedium spectabile* in fine health.—J. M., *Haukechurch, near Lymington, Decem.*

Laburnum Fences.—How can I make an ornamental Laburnum fence similar to that in the garden of the Royal Horticultural Society at South Kensington?—D. [Plant young Laburnums in a slanting direction, about 6 inches apart, or more, if large. When you have planted one tree leaning in one direction, plant another in the opposite direction, so as to form a trellis work, and so on to the end of the hedge you wish to make. Where the trees cross each other, remove a small piece of bark from each, tie them together, and clay them as in grafting; this will cause the trees to unite, and the result will be one of the prettiest and strongest fences imaginable.—J. M.]

The Blue Gum Tree (Eucalyptus globulus).—Would this tree suit our climate? Do you believe in the properties attributed to it?—B. [The Eucalyptus will live in England in mild districts, but is liable to be cut down by severe frosts, and is much too tender for cold or northern districts. It thrives best in warm temperate regions such as California. It is certain that districts known to be malarious have been found perfectly safe since this tree has been planted in them abundantly. Whether the so-called fever-deströying property is peculiar to this tree is doubtful; it seems to us, however, fair to assume that if malaria arises from decaying vegetation over large areas of low-lying land, its antidote is likely to be found in abundance of vigorous evergreen vegetation. The Eucalyptus, moreover, is a beautiful and valuable tree in temperate countries, and well worth planting extensively, apart from sanitary reasons.—Ed.]

THE INDOOR GARDEN.

THE HUMBOLDT ORANGE LILY.

(LILIUM HUMOLDTI.)

THIS is one of the most stately of Californian Lilies, growing, as it does, from 6 to 8 feet in height. It has deep glossy-green

was shown by Mr. Law, of South Lodge, Enfield, at one of the recent floral meetings at South Kensington. Mr. Tanton, of Epsom, who has kindly furnished us with the following memoranda concerning this and other species, also exhibited a fine plant of it on the 20th ult., at the Crystal Palace:—"The taste," he says, "for new Lilies being on the increase, and the kind of treatment which they require being

The Humboldt Orange Lily (*Lilium Humboldti*).

leaves, eight or nine in a whorl, and bears about the same number of large orange flowers in a somewhat lax spike. Of these our illustration furnishes a good idea as to form and markings, but not as to size; those represented being little more than half their natural size. Of this Lily, for the introduction of which we are indebted to Mr. Bull, a splendid plant

as yet ill understood, some growers complaining of their bulbs not starting, others that they split to pieces during the period of rest, a few simple instructions on such points may not be without interest. During February last I received overland from California, *Lilium Washingtonianum*, *Humboldti*, *Pardalinum*, and others; these were immediately potted

in rough turfy and very fibrous peat, loam, and leaf mould, to which was added a good proportion of washed river-sand; they were then stored away under a stage in a cool pit, and kept without water until young growths had been pushed up about 6 inches in height, when they were watered with very weak manure-water and kept still in the cool pit. All the plants of Humboldt, thus treated, have flowered, and I augur for this species, both from its value as a free flowerer and from its lasting properties, a very brilliant career. The plant of it which I exhibited at the Crystal Palace on the 20th ult., had been fourteen days in bloom, and it continued in beauty up to the 30th ult. After flowering I take care to keep the leaves of all my Lilies vigorous and healthy as long as possible; when the tops have died down the bulbs are stored away quietly till December, when they are re-potted, disturbing the ball of the previous year as little as possible. This is a point of importance, for I find disturbing and uncovering the bulbs to induce them to split, to shed their scales, and to rot. This is particularly the case with the Californian species, or those which have their leaves arranged in a whorl. The beautiful *Lilium auratum*, if treated in this way, will always yield fine flowers, and permanently improve in vigour."

THE SIMPLEST WAY OF GROWING FUCHSIAS.

YOUR readers are doubtless familiar with the habit which the old Fuchsia Riccartoni assumes when grown out of doors in those situations where, through the severity of the winters, it is compelled to assume a semi-herbaceous habit, dying down in winter, and springing up again in summer from an annually increasing stool, until it attains the size of a goodly bush. I have often thought what magnificent specimens such plants would make if transferred to a pot, with their profusion of flowers; but how much more imposing would some of our fine cultivated varieties appear grown in the same way. Imagine a plant of a good variety grown in a 12-inch pot, and furnished, perhaps, with a hundred or more unpinched shoots 2 or 3 feet in length, and loaded with bloom—a circular ball, in fact, but graceful and perfectly free from anything like that trained formality which we too often see at exhibitions. A group of such massive specimens on an exhibition table would make the attenuated pyramids which we have hitherto been accustomed to admire to appear more attenuated still, and in a less favourable light. Not so long ago I saw a number of specimens of the kind I have described; they had not been grown for exhibition, but had simply been allowed to assume the bush habit, because the gardener had no time to attend to pinching and training; but he had succeeded nevertheless in producing a number of plants for vase, &c., work in the house such as one seldom sees. The advantages of this, which may be called the natural system, are that the plants can be grown with less than one-tenth of the labour usually bestowed upon specimens so-called, flower better, and are better suited, as a rule, for decorative purposes. It is not difficult to get up a stock of such plants. Those who have Fuchsias one year old or more, have only to cut them down to the pot, and they will break away from the bottom the first year, perhaps, only six, eight or twelve shoots, according to the age of the stool; but, in such a case, the number may be increased by pinching the shoots when they are about 2 inches in height. This will multiply them considerably, but no further stopping must be done. Plants may be cut down at any time while they have still growing vigour in them. At the end of the season the plants must be cut down again, and stored away till spring, when they should be partially shaken out, and potted at once in the pots that are to last them for the season, as, when grown in this way, any interruption of growth through "shifting on" is not desirable. The size of pot will, of course, depend upon the size of plant that is wished; the size of the specimen will be just in proportion to the root-room, and the room and light which they receive. Neat little plants, in 4 or 5-inch pots, may be had, or they may be grown much larger according to fancy or requirement.—*The Gardener.*

SIR GEORGE ROSE being introduced one day to two charming young ladies, whose names were Mary and Louisa, he instantly added, with a bow, "Ah, yes! Marie-Louise—the sweetest Pear I know;" a compliment almost worthy of being coupled with that most beautiful one of Sydney Smith, suggested by the Sweet Pea. A young lady, walking with him in the garden, paused to examine a favourite flower on which she had taken great pains. "I am afraid, Mr. Smith," she said, "that this Pea will never come to perfection." "Then allow me," taking her politely by the hand, "to lead perfection to the Pea!"

THE KITCHEN GARDEN.

BROCCOLI.

THOUGH June is the month in which most gardeners try to get their plantations of Broccoli finished, yet July has often arrived before the work is done. I have planted in August and had nice heads, but the sooner the planting is done after the beginning of June the better. Though planting early ensures the finest plants and largest heads—if very large heads are desirable—I never found the time of sowing or planting to affect the plants as regards the time they came in. I have sown at different dates, from February till the middle of April, and planted from May till August, but the crop never came in either sooner or later in consequence. I have, therefore, for many years, always sown all at the same time, and planted at the same time, for convenience sake; and, by planting a good many varieties, have always ensured a good and regular supply throughout winter and spring, when the winters were reasonably mild—for it is certain that no practice as to time of sowing or planting will ensure the heads forming at a certain time, if during winter we have protracted periods of frost or cold, during which all growth is at a standstill. It is a good plan to keep on the heels of Broccoli with the Wallcheren Cauliflower. I have never found a variety so good as this old sort for resisting "buttoning" in dry summers and withstanding frost. I sow and plant it as late as possible, and have had it at Christmas, and later when severe frost held off.

Selection of Varieties.

The following selection of a dozen or more sorts does not include all the newest kinds, but it comprises the best of old and new, so far as my experience goes—and I have grown all the sorts named, and some of them for a long time. I give the names in the order in which they succeed one another in coming into use; Grange's Early White (an autumn variety), Early White Cape, Osborn's Winter White, Snow's Winter White (an excellent variety), Chappell's Cream, Gordon's Late White, Dilecock's Bride, Shearer's Late White, Knight's Protecting, Wilcove's Superb Late White, Carter's Champion, and Cattell's Eclipse. Some of the first named in this list come in pretty close upon one another, and are all fine sorts. The three last named are also first-rate sorts, and specially valuable on account of their lateness. Cattell's Eclipse is, I believe, the very latest. I have had it late in June, and by cutting the last heads with the leaves, and putting them in an ice-house, they will be in good condition after the summer Cauliflower has come in even in late seasons. It is advisable to plant a few good sorts, although space may be limited. A dozen rows may include a dozen different sorts, if a succession is wanted; for when one sort comes in, it is soon over.

Preparation of the Ground and Planting.

Though it is by no means an unusual thing to see nice little heads of Broccoli about the size of a teacup, or larger, in cottagers' gardens where the soil is seldom turned over more than a spade's depth, and not over liberally manured, yet the plant likes a deep and rich soil. If practicable, the ground should be trenched two or three spades deep, or at least double-dug. When there is not time for doing either of these, then the ground must be dug over a spade deep only, taking care to break the soil up thoroughly, as deeply as a good spade will do it, and working in some well-decayed manure at the same time. And here let me say a word about single digging. An indifferent man will simply shuffle over the ground, inserting his spade at an angle of 45°, and turning the soil over to a depth of about 6 inches, while a man who understands how to dig, or who is looked after and made to perform his work properly, will keep a straight and open trench, put his spade in perpendicularly, take thin spits, and turn the soil over thoroughly, breaking it well as he goes on, and do the work generally as it should be done. There is a vast difference between good and bad digging, and I never met with a labourer out of a garden who knew how to dig, however good a workman he might be in other respects. If the soil is broken up well in the trench, I never care about the surface being a little rough; a raked surface among

vegetable crops is an unmitigated evil at any time. Planting should be proceeded with as soon as the digging is finished. Here we invariably plant from $2\frac{1}{2}$ to 3 feet apart, if the planting is done in June or July, and the plants are always more crowded than is desirable by October. When planting is deferred till August they need not be allowed so much room. I always like to let the same man plant the whole crop. If the weather is dry, the seed-bed is watered well the night before to soften the soil. The following day the man, armed with a big basin half filled with puddle, consisting simply of soil and water and a little soot, and a steel fork, proceeds to loosen the plants in the bed and then to pull them up with the whole of the tap root to each, and to place them with their roots in the puddle till the basin is filled. He then marks off his ground, puts his line down, and, with a dibber about 3 inches in diameter, he makes a hole deep and wide, that there may be no obstacle to getting the long tap root down straight to its extremity. Then the dibber is pushed down again just at the side of the hole and parallel, to the same depth, and squeezed up firmly to the plant. This ensures the whole of the roots being brought into contact with the soil up to the neck, instead of being "hanged;" and so the work proceeds. "Buttoned" Cauliflowers and stunted plants are in many cases caused by bad planting. They are put in with broken and mutilated roots; and those that do happen to have a tap-root most likely have it bent double in getting it into the hole, and, instead of the point being at the bottom of the hole, it will probably be sticking up above the surface. I have so often seen the consequences of careless planting, that I think it right now to draw attention to it. No one should wait on wet weather for planting Broccoli if it is long in coming; get the planting done as soon as you can, and water well once or twice, and they will do till the rain comes. True Broccoli never "buttons," let the weather be ever so dry after planting. When the plants are fairly established, and have grown a little, they must be earthed up with the hoe, more to prevent the wind from twisting them about than anything else. Towards the end of October all the plants should be partially lifted with a spade, and laid with their heads to the north, to check and harden them, in order to enable them the better to resist frost.

J. S. W.

Early Dwarf Peas.—Among these Laxton's Unique, a variety that received a first-class certificate at Chiswick in 1872, is one of the best. It originated in the same batch of seedlings as produced William the First, and is, indeed, a reproduction of that fine early kind, with this difference, that it grows only to a height of $1\frac{1}{2}$ feet, whilst William the First rises up to 3 feet. Dwarf Peas are preferable to tall kinds as they can be sown in rows from 2 to $2\frac{1}{2}$ feet apart, and, laid in the ordinary fashion, will yield as heavy a crop as the same sorts will if sown in rows at $3\frac{1}{2}$ feet apart, and then staked, or, as can be got from tall Peas sown in rows 5 feet apart. Moreover, in small gardens, where a rapid succession of crops is of the utmost importance, a good crop of Winter Greens can be got forward early amongst dwarf laid Peas, and this result could not be obtained if they were staked. I find that our market growers are gradually getting rid of tall kinds, as they are peculiarly subject to two evils. If the season be dry, the moisture of the ground is exhausted before the crop is produced, and thus a poor one is the result; whilst, on the other hand, if it be a damp season, then so much growth is engendered that in gathering the first pickings, the haulm becomes so twisted and broken that the future crop is materially checked. Dwarf kinds are not subject to either of these evils, and the crops are gathered from them with ease and rapidity.—A. D.

Ornamental Rustic Work for the Garden.—Messrs. Cave, of 40, Wigmore Street, who are so well-known for the manufacture of plant-screens, flower-baskets, &c., for indoor decoration, have called our attention to some rustic work of distinct and novel character and much taste in workmanship. It is formed of a variety of woods, the most desirable parts for this purpose being chosen from extensive plantations, and carefully seasoned before being used. Tables, garden-seats, and large lawn flower-baskets, are manufactured of these materials; the tables being especially good in form and workmanship, and the seats and chairs also excellent. The large lawn baskets do not seem likely to be so useful, inasmuch, as if properly planted, much of the choice rustic work would be obscured by the plants.

THE PHYLLOXERA OF THE OAK.

(Discoveries of Balbiani.)

THE *Academy* contains an abstract of a paper by Professor Balbiani, detailing his observations on *Phylloxera quercus*, a species allied to the *P. vastatrix* which has occasioned such ravages among the Vines. The Vine pest can live under ground as well as in the air, and its most destructive work is performed on the roots of the plants to which it obtains access through cracks in the soil. Vines grown on clay lands are most exposed to its assaults, as they become extensively fissured in hot weather, and the best mode yet discovered of checking the mischief is by freely inundating the soil. It is, however, evident that this remedy cannot always be applied; and M. Balbiani studied the life history of *P. quercus*, in the hope that it would throw light upon the development and proceedings of its Vine relative. He tells us that somewhat late in spring the first individuals of the Oak *Phylloxera* may be seen in the shape of pale yellow larvæ on the under surface of the leaves, each one occupying the centre of a yellowish spot produced by pricking into the leaf. These larvæ grow without changing their position; and, after attaining a length of about a millimetre, they surround themselves with a number of eggs concentrically arranged. The development of these eggs commences almost as soon as they are laid; and in a few days the young escape and wander to a fresh part of the leaf, in which they plunge their sucking tubes, causing the formation of a yellow spot, which, like their parents, they never leave. Generations thus succeed generations, until the entire surface of affected leaves are covered with phylloxera of all sizes. When full-grown, M. Balbiani figures them as pear-shaped, very broad in the middle, blunt at the head, and very narrow at the posterior segments. The sucking-tube of the mouth reaches as low as the third pair of legs; and the creature, exclusive of its antennæ, looks a little more than 2 inches long when magnified fifty times. Until about the middle of August, in the climate of Paris, only wingless or larval phylloxera are produced; but, from then till the end of the month a certain number of the larvæ are transformed into winged sorts, after passing through the stage of red chrysalids; the winged form, according to Balbiani's figure, representing a magnification of fifty times, appears under that power 5 inches across from tip to tip of the larger pair of wings, the body about 2 inches long, and the sucking month-tube short, not reaching to the segment carrying the second pair of legs. The lower wings are much smaller than the upper ones, and each one is furnished with a small pair of hooks on the upper edges, about one-third from their tips. Hitherto no one had succeeded in discovering males of the phylloxera, and in no female organ could any spermatozoa be detected; consequently, there could be no doubt that the ordinary generations were parthenogenic. In the females on each side of the oviduct canal are two pouches, connected with glands corresponding with the usual colloidal glands of insects, and supplying the substance investing their eggs. Between these is a pouch like that for receiving spermatozoa, though none have been found in any case. The question to be decided was whether, and, if so, when, the phylloxera, like the aphids, produced males and the females laid fecundated eggs. On examining the individuals destined to be transformed into winged insects, no external character differentiated them from the wingless generations; but an examination of internal organs showed their reproductive apparatus to be slightly developed. Thus, while the egg-laying larvæ contained a variable number of eggs more or less matured, these individuals only contained eggs so slightly developed as to be little distinguished from the other contents of the ovary. It was observed that the winged insects did not remain on the leaves longer than was necessary for the hardening of their integuments, and very seldom laid eggs upon them. In calm weather they remained longer than when it was windy, confirming the remarks made by naturalists concerning other insects, and notably by Morren with regard to aphids, that they availed themselves of air currents to help their flight. But when did they go, and where deposit their eggs? In September M. Balbiani placed some twenty winged females in a bottle with a fresh Oak leaf, in which they thrust their sucking tubes without delay. The next day, however, some were uneasy and moved about, depositing here and there an egg. Others, after wandering about, returned to their first place, and laid their eggs in a heap, and others, again, left the leaf altogether, and laid an egg here and there on the sides of the bottle. In two days all had finished laying, and soon after they died. The eggs were alike in shape, but some were twice as big as others. When the hatching came the small eggs produced small red larvæ, and the big ones large yellow ones—the small being the males, and the larger ones the true females of the species. M. Balbiani subsequently found that the winged sorts laid their eggs among the old scales at the base of the new shoots of the trees, and that they were hatched in about twelve days; and now comes the most curious part of his discoveries; both males and

females from their eggs were destitute of alimentary and digestive organs, as male rotifers have long been known to be. They have no suetorial mouths, no stomachs, &c., but their reproductive apparatus is highly developed, and they spend their short lives in the formation of fecundated eggs. The ovary of these females is much simpler than in the parthenogenetic forms; instead of two ovaries, each with from two to six ovigerous tubes, there is a single tube in the middle of the body. These females lay only one egg in fissures and cracks of the Oak bark; it is a "winter egg," neither like the egg of the parthenogenetic females, or those of the winged insects. April is the time for hatching these winter eggs. The first generation thus produced is extremely fertile, one of them being seen on April 25th with eighty-seven eggs, which, in two or three days, were increased to more than 100. In the summer, these females are less prolific, the ovarian tubes diminishing in number until at last only one is found. Thus the vital energies of the parthenogenetic females become exhausted, and the reappearance of the males is requisite for the continuance of the race.

GARDENING FOR THE WEEK, AND AMATEUR'S CALENDAR.

The Flower Garden and Pleasure Grounds.

THE staking and tying up of climbers and the pegging down of dwarf-growing plants are operations which will require constant attention. Although we have of late been favoured with refreshing rainfalls, fine foliaged, or what are known as sub-tropical, plants should still be supplied with abundance of water, and the surface of the beds should be well mulched with good rich manure, to check evaporation, and assist in the production of a fine healthy luxuriant leafage, which constitutes the principal beauty and attraction of such plants. The unsightliness of the manure may be easily concealed by the mowings of lawns, and the margins of the beds should be neatly covered with green Moss, which the occasional waterings will keep in good condition. Wherever carpet-bedding is practised this must also have constant attention in the way of pinching in, and regulating the growth of the various plants employed for that purpose, so as to preserve the outlines and patterns of the beds. Let decaying blooms of Roses be cut off as soon as the petals have fallen, or are about to do so. The autumn flowering kinds may now be cut slightly back, and if the plants are encouraged by mulching and watering with well-diluted liquid manure, and at the same time kept free from insects and mildew, an abundant supply of blooms may be reasonably expected during the month of September, and even the early part of the following month. The present is also the most suitable time for budding Roses on the Briar-stock, an operation which should, if possible, be completed during this month. All flowering shrubs, as soon as they go out of bloom, should have dead and decaying flowers removed; and, when necessary, the plants should be cut back. Box edgings may also now be trimmed; and wherever divisional lines are formed by means of Sweet Briar or the common evergreen Privet, they should also now be cut. Few plants are better suited for forming low ornamental hedges than the Privet; but, being of free growth, it requires to be clipped several times during the season. The common Yew (*Taxus baccata*) is also an excellent hedge-plant; but it is of slow growth. There are, however, several other hardy Coniferous trees to which this objection does not apply, such as *Cupressus Lawsoniana*, *Thuja Lobbi*, *Thujopsis borealis*, &c., all of which are well suited for ornamental hedges or screens. Where such already exist the present is the most suitable time for cutting or rather clipping them. But, when such hedges or screens consist of large-leaved plants, such as the common or Portugal Laurel, it is then advisable to prune with the knife, in order to avoid, as much as possible, the mutilation of the leaves. Dwarf Coniferous trees, and ornamental shrubs of various sorts, are frequently used in the embellishment of Italian and geometrical gardens; and, where that is the case, it is generally necessary to preserve a certain amount of uniformity as regards shape and size; and the present is a suitable time to attend to the cutting or trimming of such specimens. Among plants well suited for this purpose are the Sweet Bay, the Portugal Laurel, the *Laurustinus*, &c., trained in the form of standards or otherwise, together with various sorts of Cypressess and Junipers, and other plants of a drooping habit of growth; also the Irish Yew (*Taxus fastigiata*), generally trained in the form of pyramids, and on which are sometimes grafted the gold and silver striped varieties of the *Taxus baccata* or common Yew, a union which produces a very striking effect, as do also trained specimens of the fine-foliaged *Acer Negundo variegatum*, which, although deciduous, produces, nevertheless, during the summer months a very pleasing contrast when associated with sombre or

dark-foliaged plants. Continue to extract Plantains and other broad-leaved plants from lawns, and occasionally take an opportunity, after a considerable rainfall, to well roll all dressed ground. This will, however, seldom be necessary where a heavy horse machine is used; and, where that is employed, avoid, by all means, a too close approach to fine specimen Coniferous or other trees upon the lawn. Whatever portion of surface the mowing machine may not have reached should be neatly cut with the scythe on the following morning; and, at the same time, the margins of walks and clumps should be trimmed or clipped with the grass-edging shears, an operation quite indispensable to neatness and high keeping. Carnations and Cloves may now be layered, and cuttings of Pinks and Picotees may be inserted in a mixture of sand and finely-sifted leaf soil under hand-glasses, which should be placed on the north side of a wall, together with cuttings of any hardy herbaceous plants which it may be desirable to increase. In layering Carnations, Picotees, or Pinks, first prepare some soil, consisting of two-thirds loam, one-third well-decayed and finely-sifted manure or leaf-mould, and add to the whole a sixth of sand; then remove a little of the surface soil from around each stool, cut away weakly shoots, and strip the leaves from a portion of the stem next the ground. With a sharp thin-bladed knife, split up the portion of the stem cleared of leaves, beginning a little below one of the joints; and turning the top of the layer upwards, so as to throw the heel or tongue downwards, fix it firmly in the fresh soil by means of a wooden peg, putting it into the ground below the split portion of the stem. When all the layers of each stool are layered, place as much of the prepared soil firmly round the stool and about the stems as will keep all steady and firmly in their places; give a good watering through a rose, and keep them watered at least three times a week should the season be dry. At the time of layering remove all stems from which the flowers have faded or been gathered. Should birds prove troublesome, as they frequently do in dry weather, by scraping about them and scattering the fresh moist soil, it is a good plan to place some flints or round stones about the plants; this keeps birds from removing the soil, and prevents evaporation.—P. GRIEVE, *Culford, Bury St. Edmund's*.

Indoor Plant Department.

Conservatories should now be gay with Balsams, which should be liberally supplied with manure-water; in order to secure a succession of blooming plants, some should have all their flower-buds removed until about four or five weeks before they are required for use. Young Fuchsias should now be full of flower, as should also older plants of them trained to rafters in the form of climbers; these should be well attended to as regards thinning and watering. It is considered to be bad practice to thin out too much of the wood at any one time; on the contrary, they should be gone over frequently, and as they always emit flower-buds at the joints as they advance in growth, shoots that attain too great a length should be removed, giving such as remain a better chance to furnish fine flowers. Pelargoniums will now, for the most part, be done flowering, with the exception of zonal kinds, which should be encouraged. Annuals of April and May sowings should now be in full bloom. Coleuses should also now be very effective; these are always best when produced from early spring cuttings; a few old plants only should be retained through the winter, in order to furnish cuttings late in February and March. Coleuses, when bushy and well-grown, make charming vase plants, edged with *Tropæolums*, Ivy-leaved *Geraniums*, *Eschyanthus*, *Hoyas*, *Convolvulus mauritanicus*, variegated *Panicum*, &c. Amongst the best kinds of Coleus are Queen Victoria, Duke of Edinburgh, Princess Royal, Marshallii, Bausei, Prince Arthur, Beauty of St. John's Wood, Golden Gem, Hector, Wilsonii, Reevesii, and Telfordii aureus. *Plumbago capensis* should now or very soon be one of our finest greenhouse plants, both in the shrub form and that of a climber. Camellias planted in borders should be syringed daily in warm weather. In order to give a little floral relief, pots of Japan Lilies, such as *speciosum*, *roseum*, and *punctatum*, should be placed here and there, when they come into bloom, among the Acacias, Camellias, &c. These Lilies should be top-dressed with rough lumpy loam and manure. Lilies in pots that have done blooming should be laid on their sides against a wall or fence, in such a manner as to prevent rain from reaching them. Specimen Azaleas should, if possible, have a house to themselves, in which they can be placed near the glass. Hard-wooded greenhouse plants, such as Heaths, Epacrises, and many others, may now or soon be set out of doors on beds of ashes, and carefully watered; the ground about them should also be well saturated at least twice a day in bright weather. In stoves, *Allamandas*, *Bougainvilleas*, *Clerodendrons*, and *Stephanotis* will be blooming freely, and when allowed to ramble over a trellis on the roof they have a much finer appearance than when trained on

pot trellises, as seen at exhibitions. Stoves at this season are not generally very gay, the principal flowering plants in them being *Ixoras*, *Gloxinias*, *Gloriosas*, *Gesneras*, *Strelitzias*, and a few others. *Marantas* growing freely, if likely to become pot-bound, should be again re-potted; plants of *Cyanophyllum magnificum*, when growing freely, should likewise be shifted a second time, using for the purpose good yellow loam, a little peat, decayed hot-bed manure, and white sand. *Caladiums* should be tied and trained rather openly, so as to permit young leaves free development. *Sonerilas*, *Bertolonias*, and similar fine-leaved plants, are much more highly coloured when grown under bell-glasses perforated at the top, and otherwise treated like *Anacochilus*, than when grown in pots unprotected.

Orchids.

Laelias, small *Cattleyas*, *Barkerias* and other Orchids on blocks, or in hanging baskets require very careful attention, especially during hot sunny weather. It must be remembered too, that plants suspended at the highest points in the house, viz., immediately under the glass, are frequently in a temperature 8° or 10° higher than those placed on the stages and side benches, and that they, moreover, receive more light; circumstances which, combined, render it necessary to keep them supplied with regular and copious moisture at the root; such plants also generally have less absorbent compost round their roots than others differently circumstanced, and this is another reason why they should be syringed or dipped into water more frequently than plants in pots, and in a moist compost. The cause of many amateur cultivators failing to grow epiphytal Orchids on blocks, or rafts of teak, as well as in pots may generally be traced to irregularity in watering, or lack of moisture at the root. Autumnal flowering *Laelias* grow best without much *Sphagnum* around their roots; I have, however, grown them on earthenware blocks modelled from natural branches, with success. These are hollow and perforated with circular holes at the side. In order to keep them perpetually moist they should be filled with fresh *Sphagnum*, and saturated with tepid water every morning. After the plants have made their growth, and during dull wintry weather, when they must be kept comparatively dry at the root, the Moss may be removed, for, if left when dry, it only serves to harbour cockroaches, wood-lice, and other vermin. Cool Orchids making growth must be liberally supplied with moisture and those in flower may be removed to the conservatory, or even a sitting-room, without injury. Small or delicate plants should be covered with a glass shade which, while it effectually obviates dryness, cold draughts or sudden fluctuations of temperature allows the beauty of the plants to be seen equally well as if wholly exposed. Indeed I often think that glowing colours and fresh foliage look richer under glass shades than when not so protected; nor do I stand alone in this matter, for our principal nurserymen frequently adopt the practice of placing delicate plants under glass at exhibitions.—F. W. BURBIDGE.

Hardy Flowers.

These have improved wonderfully during the past fortnight, many of the stronger growing perennials having made such growths as to render tying and staking constantly necessary. Cuttings of plants which it may be desirable to increase, should now be taken off and struck. Some kinds, such as *Pentstemons*, *Iberises*, &c., may also now be layered as soon as possible. Any new plants recently received should, if practicable, be divided into as many pieces as possible, and re-planted, giving them at the time a good watering. Seedling perennials in pots, sufficiently strong to bear pricking off, should receive attention; while plants from early cuttings, which have now become well-rooted, should be potted off into what are called thumb-pots. Further sowings of annuals for late flowering may still be made, and newly gathered seeds of choice perennials should be sown at once. Hardy annuals and biennials are now in perfection, and any of these requiring stakes should be accommodated with them for protection against strong winds. Conspicuous among plants now in bloom are the different kinds of *Lilies*, which vary in colour from the pure white of the old-fashioned *Lilium candidum* to the deep orange-yellow of *L. Thunbergianum*. Various forms of the beautiful *L. anastratum* are also highly attractive in many places, and so are the flowers of *L. Humboldtii*, *Brownii*, and *longiflorum*, in large collections. Several plants of the Composite family are, likewise, now very ornamental, particularly the tall-growing *Achillea filipendulina*, with its large flat heads of yellow flowers; also several of the *Gaillardias* with rich orange-yellow flowers, and *Coreopsis auriculata*, the blooms of which are of a clear golden-yellow, and produced in abundance. The old Everlasting Pea is likewise now in perfection in many places, and associated with it should be the white flowered form of that species. *Lychnis chalcodonica*, a very old garden favourite, is now producing clusters of bright scarlet flowers, and the large and handsome blooms of various hybrid forms of *L. Bungeana*, are at present strikingly conspicuous. Of the Sage family several

are flowering freely, among which I would particularly mention *Salvia chionantha*, a plant well worthy of more general cultivation than it receives. It grows from 3 to 4 feet in height and bears an abundance of large showy white flowers. Day Lilies (*Hemerocallides*) are now at their best, and the blooms of *Alstromeria aurantiaca* are also just now very conspicuous, as are likewise those of various *Larkspurs*, both single and double; and several kinds of *Monkshoods*. Among annuals and biennials now conspicuously in flower are the different varieties of *Clarkia pulchella*, and the Corn-flower (*Centaurea Cyanus*) so useful in a cut state. The Canterbury Bell, one of the best of biennials is also nicely in flower, particularly the variety of it called *Campanula Medium calycanthema*, an excellent kind.—T. SPANSWICK.

Hardy Fruits.

Should the weather prove dry, or the soil be thin and porous, few operations tell so well on the finishing of superior fruits, as mulching the surface of wall and other tree borders, and giving them a thorough soaking with water. So much has been said in favour of a dry atmosphere for the perfect finishing of fruits, that many have carried the dry theory down to the roots likewise, and with the most disastrous results. Even the importance of a dry atmosphere has been much exaggerated. Scarcely have I gathered finer flavoured Peaches than in a dripping autumn, or in that particular condition of the atmosphere when heavy dews have wetted the fruit almost as thoroughly as a shower of rain. As for dryness at the roots, it is injurious, not helpful, to the perfect maturation of good fruit. Of course, the term is very indefinite, and a swamp is even worse for the ripening of fruit than a Sahara. But the root-run should be moist, not dry, if fruit is to be obtained in perfect condition as to size and quality. Lacking rain, an occasional syringing over head with the garden engine, will cleanse the leaves, invigorate the trees, and benefit the fruit up to the time when it begins to swell; beyond that period all artificial means of adding to the water supply should cease. A thorough soaking of sewage now, followed by a mulching of 6 inches in thickness of manure, will probably carry the crops of wall trees safely through. See at once to the netting up of late Strawberries and Cherries. In regard to the latter it is a good plan not to nail in the breast wood until the fruit is gathered. Thin it as much as is necessary, and then leave the young wood of Morellos or any shoots that may be needed to make blanks good in other varieties as it grew. These young shoots keep the nets off the trees, and prevent the birds from reaching the fruit. The wood, too, ripens better in this way than when trained in close to the wall. Even the shade afforded by the leaves seems to be useful for the Cherries. Some fruits (and, especially, perhaps, Grapes and Cherries) ripen better in partial shade than when fully exposed to the sun. Hence a good many of the failures of cultivators, and among them the scalding and semi-roasting, and hardening of the substance of fruits, arise from the reckless denudation of trees of branches and leaves, thus unnaturally exposing the fruit, in full growth, to an excess of direct sunlight. The breast wood in Apples, Pears, Plums, Gooseberries, and Cherries should soon be stopped. Those who only stop such wood in the growing season may now do so without fear of exciting the buds, left at the base, into a premature and useless growth of wood. The object of these stoppings is twofold, to allow more light and air to play around the fruit, and to develop the buds at the base of the current year's wood into fruit buds. A third reason is to bring more light to bear upon the spurs that form on the branches of Apples, Pears, Plums, and Apricots in other places than at the base of the current year's shoots. Notwithstanding what has been said about the injurious effects of an excess of direct sunshine, doubtless a considerable amount of light is essential to the full development of the flavour of fruit, and one great object of summer pruning is to hit off the happy mean between a deficiency and an excess. The other use of summer pruning (the development of the small buds at the base of breast wood into fruit buds) is a matter of everyday experience. It can only, however, be done successfully by timing the stopping aright. If done too soon the buds will break with useless wood; if too late, the sun will not have time to round them off and fill them up with the plumpness of fruit-bearing buds. Light is also essential to the plumping out of the clusters of spurs that nestle in groups on the branches of Apples, Pears, &c. If these are densely shaded after July they will remain long and thin, and only yield a cluster of useless leaves. If well sunned, almost each of them will be browned, and plump out with a promising fruit bud. Therefore see that they are now nourished by the sunlight and strengthened by a play of free air around them.—D. T. FISH.

Kitchen Garden.

The drought in this part of the Midlands is becoming more intensified; much care and forethought will, therefore, be necessary to keep up the different successional crops. The water supply in many

gardens is often deficient, and, even where the supply is abundant, its distribution by manual labour is a heavy task in dry seasons. When a supply of water can be obtained from a source which gives sufficient pressure, it will be found, in the long run, good practice to have pipes laid about the garden, with plugs at intervals to which one or more lengths of hose could be attached for its distribution. By this means one or two men, in a given time, would do far more watering than a dozen could accomplish in the ordinary way, *i.e.*, if the water had to be carried any distance, without taking into consideration the injury that is often done by so much trampling of feet. Advantage should be taken of the present dry weather to secure a good stock of the various kinds of herbs for drying for winter use. If tied up in small bunches and suspended from beams or rafters in a dry airy shed, they will dry gradually and without loss of strength or flavour. Cut down a portion of the Mint bed to produce fresh young growth for late summer and autumn use. Peas of the Ring-leader section may now be sown, but the ground selected for them must be in good condition, and the trenches flooded with water before sowing. This is also the best time for making a large sowing of Turnips for autumn and winter use. The Red Stone should be the principal variety relied upon. Plant out Cauliflowers from the May sowings for autumn use, and, where the ground is not sufficiently rich for this crop, the following plan may be adopted with advantage: Make holes 1 foot square and 15 inches deep, 2 feet apart all over the space intended to be planted, put into each hole two spadefuls of rotten manure, and return the soil, leaving, at the same time, a basin or hollow space in the centre, in which the plant should be set and well watered in, and, if dry weather continues, mulching should be had recourse to, to keep the earth cool and moist; of course, in deep rich land this mode of concentrating the manure for any particular crop may be unnecessary; but, in all doubtful cases, a little extra pains, in this way, especially in a season like the present, renders less after labour in watering, necessary. Box edgings have made but little growth this season, but advantage should be taken of showery weather, when it occurs, to have them cut and the walks well rolled.—E. HODGKIN.

Cottagers Gardens.

These should now be about at their best, and every inch of space occupied. As Potatoes and other early crops are cleared off, the ground should be immediately occupied with Broccoli, Winter Greens, Celery, and Turnips in quantities proportioned to the consumption. All hedges about such gardens should now be pruned, and the walks, narrow though they may be, should be kept scrupulously clean. Climbing plants on walls should now be slightly pruned and young growths nailed in. The flower borders, if any, should be gay with herbaceous plants, annuals, and a few of what are called bedding plants to give colour in autumn. Window plants should receive daily attention as to watering and removing decayed leaves, and a reserve of such plants should be kept constantly in readiness to succeed such as are past their best. *Calceolarias*, now nearly over, should be succeeded by *Fuchsias*, *Geraniums*, *Balsams*, and fine-foliaged plants, and the aim should be not a feast of bloom one week and a fast the next, but a gradual change, so that the seasons may be linked together in floral beauty. All crowding of plants should be avoided, as it is only by allowing room that individual beauty and effect can be obtained.—JAMES GROOM.

PRECAUTIONS AGAINST A DEFICIENT WATER SUPPLY.

THE Local Government Board have issued the following circular to the sanitary authorities throughout the country, urging the taking of precautions against a probable deficient supply of water from the long continued drought:—"Sir,—I am directed by the local Government Board to state, that in consequence of the long continuance of dry weather, their attention has been drawn to the fact that in several parts of the country the ordinary water supply has become considerably diminished, and there is reason to be apprehensive that, as the summer advances, the evils arising from this cause will be much more seriously and extensively felt. Among such evils must be included the very serious danger to health which will arise if, for want of a better supply, recourse is had to polluted water. Under these circumstances, the Board think it right to point out to the sanitary authority the importance of taking steps to inform themselves fully of the nature and extent of the existing water supply in the several parts of their district, and the sources which may properly be relied upon for the purpose of supplying any present or prospective deficiency. The Board need scarcely remind the sanitary authority that one of the chief duties which the Legislature has imposed upon them is that of providing their district with a sufficient supply of water, and the Board cannot too strongly impress upon

them the expediency, at the present time, of adopting every available precaution for the storage of wholesome water in those localities which are like to suffer from drought. With this view it is desirable that the sanitary authority should make a careful examination of the existing sources of supply, so that they may, as far as practicable, be economised, and that steps may be taken, where necessary, to obtain an additional supply. If any part of the district is within the limits of a water company, the attention of the company should, with the like object, be directed to the points lastly referred to. The sanitary authority are aware that, if there is no such company, they themselves may not only construct and maintain water-works, but also dig wells, and do any other acts necessary for providing a water supply for their district. It is, therefore, competent for them, in case of need, to provide, by means of water-carts and other like expedients, a temporary supply for domestic use, and for flushing sewers and drains; and the cost attendant upon the adoption of this suggestion, which would be comparatively small, might be wholly or in part reimbursed by a moderate charge for the accommodation. I am directed to add that the greatest care must, of course, be taken with regard to the purity of the water which the sanitary authority distribute; that no supply should be used which is not perfectly safe from pollution by excremental matters or other filth; and that other impurities, if the water contains such, should be removed from it by filtration or otherwise, before it is delivered for domestic use.—I am, Sir, your obedient servant,

"Whitehall, June 29, 1874.

JOHN LAMBERT."

EDINBURGH BOTANICAL CLUB.

THE following is an extract from verses submitted to the members of this club at their meeting at Easter Duddingston Lodge, on 3rd July, 1874:—

Of the heavens and their changes but little we know,
Though much they affect us poor mortals below.
If our sun, as avern'd, be a changeable star,
As some orbs in far space most undoubtedly are,
Then changes may follow on earth, air, and sky,
And the plants of our planet be affected thereby.
Change, change, nothing but change.

McNab was the first men's attention to draw
To the baleful effects of some unobserved law—
In the fruits that once ripened, but ripen no more
In our northern climate. Whereas we had store
Of Ribstons, Greengages, Figs, Peaches, and Pears,
All matured in the open in long bygone years,
Which with fifty things more I can't specify here,
Were brought to our markets and shows year by year;
But now, tho' we pettle such things on the wall,
'Tis rarely we get one ripe fruit after all.
As of fruits, so of vegetables, *à la mode*, Tomatoes,
Once reared in the border as we still do Potatoes,
Have, with Mushrooms and Capsicums all out of order,
Bid Scotland good-bye, and passed over the Border.
Change, change, nothing but change.

On facts such as these McNab took his position,
And proved our poor climate in a bagging condition.
Now, facts being stubborn, with so many to back him,
He feared not, and cared not, who'er might attack him,
While an editor high, both on gardening and climate,
And on all cognate subjects acknowledged as Prime,
Held the case as made out by facts *ad galatam*,
With a surplus to spare of those put before him.
Then Naudin struck in with evidence clear,
That like changes in France were experienced as here.
Yet with many concurrents, it may not be denied,
There was something to say on the opposite side;
And a chap singing "Frutex" made a very fair case,
On the tables of Chiswick in the main for his base;
But whether by these or the cycles of Schwab,
He failed, to my thinking, to damage McNab;
For cycles no longer than Schwab's in duration,
Are wholly inadequate for the occasion.

I. A. HENRY.

The Neglected Squares of London.—When we think how much good Mr. Grant's gift must do, and how much innocent pleasure he will have given, all that surprises us is that he has not long ago been anticipated. There must be many millionaires more or less connected with London, accumulating wealth even beyond their ambition, who must be casting about for means of disposing of their superfluity, and would not be sorry to raise monuments to their own memories. Many of them who profess philanthropy can find no better outlet for it than the application of their spare riches to those questionable schemes which tend to foster poverty, or at

least to discourage independence. Why should they not follow Mr. Grant's very sensible example—bestow a gift that can by no possibility be abused, and enjoy the pleasure of their own good deeds in their lifetime? But, besides these, there are other men, of still better ascertained means, upon whom such an obligation more naturally falls. There are great landlords, owners of whole districts, who administer, through a machinery of agents, blocks of house property of every class. They draw enormous revenues in a shape which absolves them in a great measure from the responsibilities they would incur were their property situated in country parishes. There can be no immediate intercourse between them and the occupants of their houses. In the way of charity they have no direct dealings, except with rectors, curates, or churchwardens; and the bounty they distribute is entirely at their own discretion. But they owe a duty, as citizens of no mean city, to the great source of their revenues. Mr. Grant has anticipated in Leicester Square the owners of ancestral domains; but there are many other places in London which may be dealt with at once, without costly and complicated law proceedings.

Leached Wood-Ashes.—Some valuable observations on the fertilising action of leached wood-ashes are contained in the annual report made by Professor S. W. Johnson to the Connecticut State Board of Agriculture. Analyses of four samples lead Professor Johnson to the conclusion that the chief fertilising element in leached ashes is carbonate of lime. The specimens examined contained from 38 to 53 per cent. of this substance. The proportion of water in leached ashes is as large as 35 per cent. When unaltered, the quantity of sand or soil and unburned coal which they contain varies from 6 to 15 per cent. As the benefit derived from their application to land is often attributed to potash, it is interesting to learn that they seldom contain more than 1 per cent. of potash.

Effects of Storms on Vegetation.—A storm of unusual severity visited the north of Italy and the south and east of France a few days ago. A letter from Antibes, in the *Débat*, states that the thunder and lightning in that district were terrific, and that the hail was driven by the wind with such force that the leaves of the trees were riddled or torn to shreds, leaving nothing but naked branches. Figs, Vines, Olives, and other fruit trees were ravaged, and some were torn up by the roots. People on the roads were felled and vehicles overturned. The hurricane did not keep a straight route, but was influenced by the currents formed in mountain gorges and in the valleys, and wheeled about, carrying ruin wherever it went. At Tarbes the hail had to be removed in shovelfuls from the foot pavements, and round Montpellier the Cornfields were almost destroyed.

Vegetable Wax.—This was the subject of a paper read before the Natural Science and Statistical Society of Eastern Asia, at Yeddo, Japan, on Dec. 6th, 1873. The delivery of the paper was accompanied by an exhibition of specimens of the material in different stages of preparation. The wax tree is in appearance not unlike our Mountain Ash, and the Bean-shaped berries, in size about that of Lentils, are gathered in the month of October. After being softened by the action of steam, to which they are exposed in stone receptacles, the berries are pressed, and the wax obtained. The substance is then purified by boiling, first in lye, and then in pure water, after which it is bleached in the sun for about fifteen days, in which latter process it becomes white, and is ready for use or for exportation. The vegetable wax, thus prepared, is scarcely distinguishable—except by a tallow-like odour—from beeswax, and is exported from Japan to England in considerable quantities.

The new Substitute for Flax.—Can you inform us what this American Wood Nettle is, that we hear of as a substitute for Flax, which a Mr. Roetz discovered in America and has introduced into Germany? What is the sense of our introducing Ramie from China if we have something as good, or better, at home?—*TEXTILIS*. [It is an old affair come up again, and it remains to be seen whether anything will come of it. About fifty years ago a clever Irishman, named Whitlow, finding that our wild Wood Nettle (*Laportea canadensis*), had a good deal of strong fibre in its bark, took some roots back to Ireland and England, introduced it as a new species under the name of *Urtica Whitlowii*, and vaunted its merits as a substitute for Flax. For some reason or other it did not succeed. Lately it has been taken up anew by a very enterprising German explorer and collector, Mr. Roetz. He has taken the same plant to France and Germany, under a new name, this time *Laportea pustulata*. And it really appears that our Nettle "is attracting considerable attention in Germany for textile purposes." It is said that the trials that have been made of it under the direction of the Prussian Minister of Agriculture gave favourable results. The advantages claimed for it are, that being a hardy perennial it is not necessary to sow the seed year after year; and that the fibre is extracted from the stalks with much less labour and cost than is required in the case of Flax and Hemp. We can only say that the fibre of the bark, which is good

and abundant in Nettles generally, is particularly fine and strong in this species; while all the central part of the stem is tender and succulent, and therefore probably easily got rid of by maceration or mechanical means. The question whether it will pay to cultivate Nettles and extract the fibre is entirely a practical one. As the Nettle in question grows in woods and damp shady places, it may be doubted if it will thrive in open and dry fields. But it grows very well in good garden soil, as we have occasion to know. Flax, however, has held the ground for several thousand years, and it is much to be doubted if it now finds a rival.—*ASA GAY, in The Tribune.*]

THE HOUSEHOLD.

Leaves for Flavoursing.—With the exception of sweet and bitter Herbs, grown chiefly for the purpose, and Parsley, which is neither bitter nor sweet, but the most popular of all flavoursing plants, comparatively few other leaves are used. Perhaps I ought also to except the Sweet Bay, which is popular in rice and other puddings, and certainly imparts one of the most pleasant and exquisite flavours; but, on the other hand, what a waste there is of the flavoursing properties of Peach, Almond, and Laurel leaves, so richly charged with the essence of bitter Almonds, so much used in most kitchens! Of course such leaves must be used with caution, but so must the spirit as well. An infusion of these could readily be made, either green or dry, and a tea or table spoonful of the flavoursing liquid used. One of the most useful and harmless of all leaves for flavoursing is that of the common Syringa. When Cucumbers are scarce, these are a perfect substitute in salads or anything in which that flavour is desired. The taste is not only like that of Cucumbers, but identical—a curious instance of the correlation of flavours in widely different families. Again, the young leaves of Cucumbers have a striking likeness in the way of flavour to that of the fruit. The same may be affirmed of Carrot-tops, which are as like Carrots in taste as may be. In most gardens there is a prodigious waste of Celery flavour in the sacrifice of the external leaves and their partially blanched foot-stalks. Scores of sticks of Celery are cut up into soup, when the outsides would flavour it equally well or better. The young leaves of Gooseberries added to bottled fruit give a fresher flavour and a greener colour to pies and tarts. The leaves of the flowering Currant give a sort of intermediate flavour between Black Currants and Red. Orange, Citron, and Lemon leaves impart a flavoursing equal to that of the fruit and rind combined, and somewhat different from both. A few leaves added to pies, or boiled in the milk used to bake with rice, or formed into crusts or paste, impart an admirable and almost inimitable bouquet. In short, leaves are not half so much used for seasoning purposes as they might be.—*P. L. SIMMONDS.*

Blancmange and Apricots.—A pint of milk, a pint of cream, half an ounce of isinglass melted with a little boiling water, four ounces of loaf sugar, three Bay leaves bruised, a stick of cinnamon broken, a tin of preserved Apricots or Apricot jam; boil the milk, sugar, cinnamon, and leaves together for ten minutes; put it into the cold milk; then strain it; add the isinglass, and let it boil up; then the cream; let it boil for five minutes. Strain it into a basin; stir it till only lukewarm. Add three table-spoonfuls of brandy. Stir it well, and pour it into a wetted mould. Let it stand in a cold place eight hours.

NOTES AND QUESTIONS ON THE HOUSEHOLD.

A Novel Way of Preserving Onions.—Mr. Baines, of Southgate House Gardens, stores his Onions in an uncommon way. They are nailed in bundles on the outside of his house; and, in this way, slightly protected from wet by the eaves, they keep, on an average, five weeks longer than those of the same varieties and of the same crop, stored in the ordinary manner. Mr. Baines says this is the mode adopted by the Cheshire market gardeners.

Dandelion Salad.—The French are so enthusiastic over this salad that great pains have been taken to improve the varieties of Dandelion, some of which we have imported into this country. The Dandelion requires a thorough blanching to deprive it of its bitterness. It can easily be grown at a low temperature, and when properly cultivated it is said to produce white leaves as crisp and nutty as the finest white solid Celery. Two varieties are highly praised in the French papers—one, which has a full round head, like a small Cabbage, and another which has long, broad, Lettuce-like leaves.

Coffee as a Disinfectant.—Roasted coffee, says the *Homeopathic World*, is one of the most powerful means, not only of rendering animal and vegetable effluvia innocuous, but of actually destroying them. In proof of this, the statement is made that a room, in which meat in an advanced degree of decomposition had been kept for some time, was instantly deprived of all smell on an open coffee roaster being carried through it, containing 1 lb. of newly roasted coffee. Does not this suggest the advisability of keeping our coffee canisters constantly corked? Of course, such as is used for disinfecting purposes would be destroyed.

SOCIETIES AND EXHIBITIONS.

EVENING FETE AT THE ROYAL BOTANIC GARDENS.

ON Wednesday evening last a grand *fête* was given by the President and the Council of the Royal Botanic Society in their gardens in the Regent's Park. This *fête* may now be fairly considered to be one of the settled events of the London season, as it certainly is one of the most pleasant of them. As a rule, people are pretty safe, as far as the weather is concerned, in fixing July for open air festivities; but, with the experience of the last few weeks, and with the recollection of the manner in which their first *fête* was interrupted by a violent thunderstorm, the Council have been kept in a state of great anxiety as to whether or not a similar disaster awaited them on this occasion. Fortunately for them and for their guests, the weather proved simply delightful, and nothing in any shape or form interposed to mar the success and the pleasure of the gathering. The arrangements for the *fête* were very similar to those of last year. The principal avenue, leading from the entrance at York Gate to the conservatory, was festooned with opal lamps along each side, the effect thus produced reminding many of the illumination of the Champ Elysées on an Emperor's *fête* day. Many of the numerous paths intersecting the twenty acres of gardens were covered in by awnings and lighted with lamps of various colours, while the flower beds and the ornamental vases throughout the grounds were also surrounded and lit up with similar lamps. Chains of globes fringed other parts of the gardens, marking the bridges and the rest of their special features. The large exhibition tent was lit with the lime light, and occasionally with coloured fires, while the illumination of the conservatory was very effective; the magnesium burners from the outside and the ever-changing electric lights from within, with a very tasteful arrangement of flowers, Ferns, and exotic plants, combining to produce a most dazzling effect. The visitors numbered between 9,000 and 10,000, including the 2,500 fellows and members of the society; and the fact that evening dress was *en règle* added considerably to the success of the gathering as a mere spectacle. The Duke and Duchess of Teck arrived shortly before eleven, and were received at the entrance by the Council, who escorted their Royal and Serene Highnesses to their seats upon the dais, the three bands meanwhile joining in the National Anthem. Her Royal Highness the Princess of Wales, who was also expected to be present, sent, through the President, an intimation to the Council of her regret that she found herself unable to attend. An excellent feature was a charming exhibition, in the large tent, of cut Roses, furnished and arranged in designs by Mr. W. Paul, of Waltham Cross; Mr. Paul had, in fact, quite a garden of cut Roses. Mr. Wills sent many van-loads of his well-grown and graceful plants to decorate the great tent, and in this way materially added to the attractions of the evening. The special feature of the show was the table decorations, which, as usual of late, were tastefully arranged. Bouquets, on the other hand, both for the table and hand, were very poor indeed. It would greatly tend to the improvements of exhibitions of this kind if the various entries composing a class were arranged together, otherwise it is most difficult for the public to compare the various productions. This also is a great obstacle to the efficient performance of the judge's part of the work. We trust these highly successful and interesting evening *fêtes* may go on increasing in brilliancy, and would suggest that next year the society would give prizes to stimulate our great plant decorators into showing us samples of their best work. There is a frequently-expressed feeling that dinner table-decorations are being overdone, but we have heard no such objections made to the floral decoration of a ball-room, or of a hall, or any other portion of a house for such a festive occasion. There would not be much difficulty in so framing the schedule, as to draw to the pleasant gardens in the Regent's Park far more attractive plant displays than have yet been seen there on the occasion of an evening *fête*. For example, we have no doubt that Mr. Wills could arrange a bank or series of groups of plants, which would be more effective than all the table-top supper decorations put together.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

ON the 2nd inst. the anniversary festival of this society, of which Her Majesty the Queen is the patroness, was held at the London Tavern, Mr. Alfred de Rothschild presiding, supported by Mr. Alderman and Sheriff Whetham, the Rev. William Rogers, rector of Bishopsgate, Major Snell, and many other gentlemen of consideration. The room in which the entertainment was given was charmingly decorated for the occasion with the choicest flowers and evergreens, in the display of which all the principal florists and nurserymen in and about the metropolis, for miles round, had contributed. The society was established thirty-six years ago, and during that long interval it has aided 214 persons down to the end of 1873, of whom sixty-two then survived, and the total sum paid to them up to the end of December last was £18,760. The funded stock of the society then amounted to £8,900. The chairman, Mr. Alfred de Rothschild, in proposing the toast of the evening, "Success and prosperity to the Gardeners' Royal Benevolent Institution," said he did not require to be a botanist to appreciate the sweet aroma of a Rose or the blushing beauty of the Violet; and it was because that appreciation of what was truly delightful was in us all, although possessed in a higher degree by some, that he ventured to say a few words on a topic which he otherwise should not have had an excuse for approaching. He dwelt on the infinite pleasure which all mankind derived from gazing upon flowers

and plants of every hue and description. Such an attempt, he said, would be to "paint the Lily," or "to throw a perfume on the Violet," for every thing that was gay and bright and joyous was associated with flowers and the fresh foliage of trees. Indeed, it was impossible to deny that they played an important part in the manifold incidents of human life. The conquering hero, on his return from a distant campaign, was garlanded with a wreath of Laurel; the gentle bride, as she was led up the steps of the altar, was encircled with the fragrance of Jasmine and Orange blossoms; and who knew how many a romance, which otherwise might have remained dormant, had not been developed by the "anonymous bouquet?" The English gardener, *par excellence*, had, by his industry, skill, and enterprise, brought the science of horticulture to a perfection which stood unrivalled, and was not even equalled in countries where the sky was sunniest and the climate less capricious. He spared no trouble or expense in introducing from tropical zones the rarest of Orchids and other exotics, and his care was unceasing in nurturing and fostering those delicate and, in many cases, half-withered plants. The chairman concluded by an eloquent appeal to the company to support the charity, in aid of which the entertainment was given, reminding them how largely gardeners contributed to the festivities of the season, and that this had been an exceptionally joyous one none, he said, would deny; for we had placed garlands of Laurel upon our Ashantee heroes, and had welcomed to our shores a fair and illustrious Princess, whose brow was still encircled with Jasmine and Orange blossoms. This and other parts of the chairman's address were much cheered. He concluded by proposing as a toast "The continued and increased success of the institution." Later in the evening the rector of Bishopsgate proposed "The health of the chairman" in appropriate terms. The guests afterwards drank to the health of Mr. Sheriff Whetham, who had honoured them with his company on the occasion. Mr. Edward Cutler, secretary to the fund, at the close of the entertainment, announced that the subscriptions of the evening amounted to £771, of which 100 guineas had been contributed by the chairman and members of his family.

FLORAL DECORATIONS AT TUNBRIDGE WELLS.

AT the annual exhibition of the Tunbridge Wells Horticultural Society, held on the 3rd inst. the classes open for different styles of floral arrangements, were so well filled that it would be impossible to describe each exhibition in detail. We must, therefore, content ourselves with giving descriptions of such only as obtained first prizes in each class. In that for a group of three pieces, the first prize was awarded to Mrs. Seal, of Sevenoaks, for three March stands, the centre one having a trumpet rising out of the upper tazza, these were most tastefully arranged with ordinary flowers and wild Grasses; wired pips of a light blue Larkspur, being placed so as to come out against an orange-shaded Begonia with excellent effect. In the class for a single piece, Mrs. Seal was awarded the first prize for a prettily arranged vase of an uncommon shape; the lower part resembled an ordinary March stand; but the upper tazza, in place of being supported on a stem rising from the centre of the lower one as is mostly the case with these vases, was supported by three slight rods which rose from the outer edge of the lower tazza. In the decoration of this stand the effect would have been much enhanced had Mrs. Seal run *Lygodium scandens*, or some equally light creeper, up the rods; this style of vase would be well adapted for a drawing-room table. The class for hand bouquets was the weakest part of the show; I do not mean as regards the number staged or the flowers used, but as regards the bouquets themselves; one and all were packed, as many flowers being used in one as might have made two, or, perhaps, three, if skilfully arranged; the best was that exhibited by Mrs. Seal, who was again in this class the fortunate winner of the first prize. It consisted of half-blown yellow Roses, mauve Orchids, and blooms of *Eucharis amazonica*, all of which blended well together. Button-hole bouquets were well represented, the first prize being won by Mr. Rust, the gardener at Eridge Castle. Perhaps one of the most attractive classes of this section of the show was that open for wild flowers arranged for effect; and anything more charming than the stand of these—exhibited by Miss Walker—to whom the first prize was awarded, could not be imagined. The vase itself resembled a March one in form, and each tazza and the trumpet were filled with Dog Roses, blue Forget-me-nots, brown-tinted sprays of Oak leaves, and British Ferns; in each tier the flowers and foliage were most charmingly intermixed. In addition to those just named, in the trumpet was placed a long trailing spray of white *Convolvulus*, which drooped down, and was twined in a most graceful manner. In the class for single pieces for table decoration, for gardeners only (the prizes for which were given by Mrs. G. Howe, Goldney), the first prize was won by Mr. R. Downing, for a very light and effective arrangement. The form of the stand was as follows:—Out of a tazza rose a glass stem, supporting on the top of a trumpet (just like a March stand with the upper tazza taken off); half way up this stem projected three tiny curved branches. In the tazza were blooms of deep crimson Roses, *Stephanotis*, blue-shaded *Statice*, &c., set off by Ferns and other foliage. The small curved branches contained blooms of *Stephanotis* and *Statice*, intermixed with fronds of *Adiantum cucullatum*. In the trumpet was an elegant plume of Ferns, Grasses, and flowers, similar to those employed in other portions of the stand; while, drooping down from the mouth of the trumpet, were long sprays of *Selaginella*, which gave a certain amount of grace to the whole arrangement, that was not to be found in the other stands in this class. The small branches, being very lightly filled, did not interfere with the view across the table; but, had heavy flowers been used in this part of the stand, such would have been the case. On the whole the floral arrangements were admirable.

GREAT SHOW AT ASTON PARK.
BIRMINGHAM.

JULY 7TH, 8TH, 9TH, AND 10TH.

THIS great exhibition was opened at the Lower Grounds, Aston, on the 7th inst. The weather was singularly favourable, being warm, but with just enough sunshine to light up the tents and to bring out the elegant outlines of the plants and the hues of the flowers to the best advantage. It was a considerable task to arrange and put into proper position the immense number of plants brought together on this occasion. As is usually the case with large exhibitions, some exhibitors who enter for competition do not put in an appearance; and, as an allotted space is reserved for each collection entered, there are certain ugly gaps where the plants do not present themselves. This necessitates alterations in the plans of those who direct the grouping of the plants, and some delay is the result. At eleven o'clock, however, the judges were enabled to enter on their several tasks; and, once commenced, the work went on smoothly, and shortly after the time announced the tents were thrown open to the public. During the afternoon large numbers of visitors passed through the tents, but at no time in the day were they inconveniently crowded. At all times locomotion was easy, except at certain points—such as the fruit, the table decorations and bouquets, and the Roses—and here many persons congregated. The general public, who are invariably correct in their estimate of an exhibition of this kind, were entertained with what they saw, and emphatic expressions of admiration and praise were heard on every hand. The success of the undertaking, in short, was complete.

Stove and Greenhouse Plants.—In the grand class of sixteen stove and greenhouse plants, in bloom, there were but three entries, and of those staged by Messrs. Cole & Sons, too much can scarcely be said. The most striking features, perhaps, of the whole collection, were two *Azaleas*—Brilliant and Cheloni—which were masses of bloom. In the collection, too, were some magnificent Heaths, including a very splendid *Erica Cavendishii*, rather past its prime however, and four others possessing considerable merit as specimen plants. The collection also included an *Aphelaxis*, handsomely and naturally grown, and an *Ixora coccinea* of splendid form and colour, but scarcely bloomed sufficiently. Mr. Cypher's collection could scarcely be called a good second, his specimens failing in size and effect when compared with those of his rival. Among them were a beautiful *Ixora amblyensis*—a very distinct and telling plant, and remarkably well grown; a grand plant of *Clerodendron Balfourii*, also a *Phenocoma prolifera* Barnesii, and *Eucharis amazonica*, admirably flowered. Mr. Marsh's collection, which, though destitute of any great distinguishing feature, contained some pretty well-grown specimens of *Clerodendron Balfourii*, *Hoya carnea*, *Kalosanthes rosea*, and others. In the class for ten stove and greenhouse plants the Messrs. Cole are again successful as first prize winners, their collection being inferior only in size to that of the previous class. Foremost in this group another *Azalea*, called Brilliant, and an *Ixora aurantiaca* were very remarkable both for foliage and colour. Here also were some well-furnished specimens of *Aphelaxis macrantha* purpurea. The amateur class for ten stove and greenhouse plants was also well sustained. We have only noticed the gems of the exhibition in the great tent thus far, which contained besides perhaps nothing more striking than the *Cycas revoluta*, *Crotons*, and *Phormium tenax* variegatum, shown by Messrs. Cole & Sons, in their premier prize in the collection of fine-foliaged plants. It is impossible to imagine a grander effect than was produced by the collection of magnificent plants, brought together in this capacious and almost circular tent, the chief specimens being grouped to good advantage.

Orchids.—These were not so well represented as might have been expected at this season. Mr. B. S. Williams had, however, some fine specimens, including *Anguloa Clowesii*, with great waxy Tulip-like flowers of a soft golden-yellow colour; *Vanda tricolor*, a splendid pan of the great Bearded Lady's slipper, the delicately-perfumed *Aerides odoratum* and *A. Lobbiani*, one of the dwarfest in habit, and most effective of all the species; the Cape *Disa grandiflora*, with gorgeous flowers of scarlet and gold; and a nice specimen of the orange-flowered *Epidendrum vitellinum*. Mr. W. E. Dixon, of Norwood

Nurseries, Boverley, had a nice group; as had also Mr. Mitchell, gardener to Dr. Ainsworth, one of the most enthusiastic of amateur Orchid-growers. The last-named exhibitor had nicely-grown well-bloomed plants of *Odontoglossum grande*, *O. Schleiperianum*, the beautiful purple-lipped *Cattleya Mendelii*, and others equally good. In the class for single specimens, Mr. B. S. Williams was deservedly awarded the first prize for *Aerides odoratum majus*, with about twenty fine spikes.

Roses.—The Rose tent was a grand sight. Several Rose shows have been held this season, but finer blooms have not before been exhibited than those which appeared at Birmingham on this occasion. Right down the middle of the tent there was arranged, on the central stage, a line of *Fuchsias*, with here and there some showy *Dracenas* and plants of *Lilium auratum*. On either side were arranged the stands of cut Roses, the nurserymen's classes on one side, the amateur's classes on the other. There were two challenge cups given in the Rose classes in addition to the money prizes; one in the nurserymen's class, for seventy-two varieties, and one in the amateur's class, for forty-eight varieties. In the class for seventy-two varieties, no fewer than ten stands were to be found; but the best came from Messrs. Paul & Son, of Cheshunt. There were about four stands in the collection that seemed to stand out from the rest by reason of the finer quality of the flowers; and to judge them accurately and decide on the best, required a great amount of care and attention on the part of the judges. They were quite three-quarters of an hour awarding the first prize in this class; and when it was given to Messrs. Paul & Son it was felt by those who had attentively looked over the flowers that the decision was a just one. In the class for forty-eight varieties, Messrs. Paul & Son were also placed first, and here the competition was close also. Twenty-four Roses, single blooms only, brought to the front a new grower in Mr. H. Merryweather, of Southwell, Notts; Mr. Cant being second. On the opposite side table were staged some of the most beautiful, because sweetest scented, Roses—the Teas; and here, in all his glory of golden uniform, was found *Maréchal Niel*, surrounded by a galaxy of white, blush, and pink beauties, redolent of sweetness and lovely charms. Specially noticeable also, were boxes containing twelve blooms each of one kind in which some groups of grand colour predominated. Here were the deep red *Alfred Colomb*, the new dark Hybrid *Perpetual Duke of Edinburgh*, the Baroness de Rothschild—the grandest blush-pink Rose in cultivation; also *La France*, a splendid flower of a flesh tint; *Marie Baumann* a crimson-red; *Devoniensis*, that lovely white Tea; and *Maréchal Niel*. The amateurs' collections of cut Roses were not far behind the fine blooms of the trade-growers. With twelve Tea Roses, Mr. C. N. Newdegate's gardener was placed first; but, looked at later in the day than when seen by the judges, the second-placed twelve were the freshest. Mr. Thomas Laxton, of Stamford, also staged a charming collection, as did many others, the different collections exhibiting every shade of colour, from the deepest crimson to pure white.

Fruit.—The chief feature in this department was the collections of eight varieties, to contain not more than two dishes of Grapes. In addition to a £10 prize, there was included a silver challenge cup, value 25 guineas. The best collection came from Mr. W. Coleman, gardener to Earl Somers, and consisted of fine Black Hamburg and Muscat Grapes, a Moscow Queen Pine Apple, Royal George Peaches, Elruge Nectarines, President Strawberries, and Brown Turkey Figs. This was well worthy of the handsome prize which was awarded to it. For Pine Apples there were four classes, and there must have been nearly 100 splendid fruits set up, the majority of the Queens averaging 5 lbs. to 6 lbs. in weight. Then came the collections of three bunches of Black Hamburg Grapes, and here the first prize was given to three splendid bunches—large, symmetrical, and crowded with evenly-sized berries, covered with a beautiful greyish bloom. These also came from Mr. W. Coleman. Not less interesting were the white Grapes, which were represented by the large amber-coloured bunches of the Muscat of Alexandria, still one of the best-flavoured Grapes in cultivation. The best three bunches came from Mr. Foster, gardener to Mr. E. Greaves, Arvonside, Warwick. The bunches taking the second prize had large berries, but they were wanting in the colour and finish that characterise first-class Grapes.

There was a class for Buckland Sweetwater Grapes, a white variety, of a less rich and luscious flavour than the Muscat, but still a good Grape when well grown. Mr. Cox, gardener to Earl Beauchamp, Madresfield Court, had some very fine examples of this well-known Grape. Three bunches of white Grapes, of any other variety than that named in the foregoing classes, were represented by Golden Champion, a large Grape, with luscious, tempting berries. Some fine Frontignans were also exhibited. Next came Peaches, of which there were no fewer than twenty dishes of rich-looking fruit; of Nectarines, there were some thirteen dishes; of Apricots, there were only two dishes, but then it is yet early for them; Figs, two dishes; Black Cherries, five dishes; White Cherries, seven dishes—all of which were very fine. Strawberries were both numerous and fine. Melons were very good, bad, and indifferent. The judges were scarcely to be envied in having to taste so many, for it must be remembered the prizes were awarded according to the flavour of the fruit. There were green-fleshed varieties, and also scarlet-fleshed; the former, generally, the best flavoured. The finest fruit was a Golden Gem, sent by Mr. W. Cox, Madresfield Court.

Table Decorations.—On a long range of side-tables were tastefully placed some charming centre-pieces for dining and drawing-room tables, consisting of glass epergnes dressed with flowers, Ferns, Grasses, &c.; and it was specially noticeable that the simplest and lightest arrangement met with the widest approval. Bouquets, arranged close by, as nice and effective as it is possible to make them, were also objects of much admiration. The bridal bouquets were exceedingly elegant, and opera bouquets were even more beautiful, as the introduction of a few rich tints of colour in graceful arrangement created more pleasing effects than a combination of white flowers only. On the opposite side-table were placed the splendid silver cups which Mr. Quilter had so liberally offered as prizes.

Miscellaneous.—Messrs. Veitch & Sons contributed a fine group of new and rare plants containing most of the novelties recently exhibited at our London exhibitions. Mr. Charles Turner had a charming group of large flowering *Pelargoniums*, very bright and effective, containing among other varieties, Corsair, Protector, Juno, Highland Lassie, Claribel, and Blue Boy, which has the deepest tint of blue of any variety yet raised; Ruth lovely hue of pink; Achievement and Scottish Chieftain, also struck us as being very effective. Clematises were shown by Messrs. Jackman and Son, of Woking, and received more than ordinary attention. These have flowers of either sombre or soft tints, and possess all those charming hues of rich purple and soft lilac, so rarely seen in hardy decorative plants. A neat group of Palms and Ferns, sent by Mr. R. H. Vertegans, of Chad Valley Nursery, Edgbaston, was much admired. A beautiful new pyramidal Ten-week Stock, named Mauve Beauty, sent by Mr. R. Dean, of Ealing, was very effective; its perfume being exceedingly rich, and its colour novel and pleasing. A fine variety of *Lilium auratum*, having an unusual amount of colour in the markings was staged by Messrs. John Standish & Co., of Asot, and specially commended as a fine variety; while Mr. J. E. Mapplebeck staged some fine hardy Ferns, for which he is so famous, and the judges awarded to several of the newer types first-class certificates of merit. Mr. J. Croncher contributed some pretty little *Haworthias*, curious *Stapelias*, Aloes, and a fine group of Agaves. Mr. Pilgrim also sent a nice collection of the last-named plants; while Mr. Pfersdorff, 73, South Row, Kensal New Town, had a fine miscellaneous collection of these now well-known plants. The last-named exhibitor has done more than any other cultivator we know towards increasing the popularity of succulents, and thousands of little specimens, from his establishment, find their way to Covent Garden and other markets, and from thence are distributed to the window gardens of the metropolis.

Horticultural Implements.—This department, from its extent and variety, was one of the most attractive features of the show. There was scarcely an article of any value unrepresented. An idea—though imperfect, it must be admitted—of the nature of the exhibition may be gleaned from the following brief description of some of the stands. Messrs. Dennis & Co., Chelmsford, were extensive exhibitors. At their stand was to be seen

spec. alba in the shape of a conservatory, named the "Villa." Their selection of greenhouses and other garden erections was numerous, and of so varied a character, as to suit the tastes of everybody; they also showed a new high pressure valve which promises to be useful; likewise a new hot-water boiler, with patent casing, by which all brick-work setting is not only obviated, but the radiation of heat is prevented, and the heated air is utilised to support combustion; another of their inventions is a water-waste preventer. Messrs. Crowley showed a lawn-mower, "The Invincible," for which a gold medal was awarded. Messrs. Felton & Sons, Birmingham, exhibited a large and varied collection of rustic furniture. Messrs. Powell & Co., of Birmingham, obtained a silver medal for a large assortment of articles, consisting of garden seats, vases, fountains, and flower stands, pumps, engines, syringes, &c. The same firm also exhibited water and hose barrows, lawn mowers, and garden tools. Messrs. Hassall & Singleton, of Freeman Street, Birmingham, furnished heating apparatus and a large number of other useful articles. One of the most attractive exhibitions was made by Messrs. Hartley & Sargent, of Halifax, who, among other things, showed boilers and other heating apparatus, the Windsor, Victoria, and other lawn mowers, &c. Messrs. Boyd & Son, of Paisley, were the exhibitors of a number of excellent greenhouses. The Alpha patent air gas-making apparatus, through the use of which everyone is enabled to supply himself with gas at a cheap rate, was exhibited by Mr. H. L. Muller, of 22, Macy Ann Street, Birmingham. The characteristics of the apparatus set forth that no heat is required in the production, the gas is made instantaneously, is of a superior illuminating or heating power to coal gas, purer and less costly. The arrangements for the fitting-up of the apparatus are in every respect simple and complete. Mr. Henry Inman, of Stratford, near Manchester, who a few years ago supplied the rustic houses, bridges, &c., for the Aston Lower Grounds, obtained a first prize for a large variety of rustic summer-houses, garden-seats, tables, and vases. The Dromore Patent Heating Company exhibited Cowan's patent compensating system of heating horticultural and other buildings, which was highly commended. Mr. Peters, 26, Carr's Lane, Birmingham, furnished all kinds of horticultural implements, seats, vases, pumps, engines, lawn-mowers, &c. To the garden furniture in this collection a silver medal was awarded. Mr. Kay, of Navigation Street, Birmingham, exhibited filters, fountains, and aquaria. Messrs. Perks & Co., of 59 and 52, Dale End, Birmingham, showed Parker's dry earth-closets, glass louver ventilators, and similar contrivances. Messrs. Follows & Bates, of Manchester, showed a large collection of the "Climax" and Anglo-American lawn-mowers. Messrs. Baker & Co. obtained a silver medal for garden arches, flower and fern-stands, garden-chairs, stools, hanging baskets, conservatory cages, aviaries, &c. Mr. Matthews, Weston-super-Mare, showed an elegant assortment of terra-cotta work, including vases, stands, fountains, statuary figures, Italian and Fern baskets, for which a silver medal was awarded. Messrs. Green & Sons, Leeds, exhibited a selection of lawn-mowers and Green's patent hot-water boilers. Messrs. A. Smith & Co., of Bath, showed their patent siphonic watering pot, to which allusion was made last week. Messrs. Mapplebeck & Son, Bull Ring, Birmingham, were awarded a silver medal for fountains and vases. Mr. J. Clark was awarded a silver medal for plant protectors and similar contrivances. For cheap garden carts Mr. W. Sawney, Beverley, Yorkshire, received a bronze medal. Garden hose was furnished by Mr. J. Pumpfrey, 5, Broad Street Corner, Birmingham, to whom a bronze medal was awarded; a similar award was also made to water appliances for garden purposes, shown by Messrs. Ball & Purser, Carr's Lane, Birmingham; also for hot water valves, shown by Messrs. Jones & Co., Broad Street, Worcester; and sand, contributed by Messrs. Fraser & Co., Leighton Buzzard, were highly recommended.

The Lawn Mower Contest.—This took place on Wednesday last, when four makers competed, viz., Messrs. Green, Barnard, Edwards (Messrs. Crowley & Co.), and Hartley & Sargent. No spaces were marked off for each machine to mow, the competing machines being merely run two or three times over a piece of Grass not exceeding 30 yards in length. No idea could, therefore,

be formed of the time in which any of them could do a certain amount of work; there was no dynamometer applied to test the draught, and each exhibitor adjusted the height of cut according to his own notion, the Grass being very short (though thickish at bottom). We do not believe half-a-dozen barrow loads, were cut by all the competing machines, which numbered about twenty. The machines entered all worked fairly well. The prizes were awarded as follows:—Gold medal, Mr. Edwards; silver medal, Messrs. Green; bronze medal, Messrs. Hartley & Sargent. The trial, so far as it went, may be considered to have been fairly carried out. It must be regarded, however, as of little value as a guide to intending purchasers of lawn-mowers, as the question as to which is the best lawn-mower remains still unsettled. Neither Messrs. Shanks, Ransome, Follows & Bates, nor the Archimedes Company.

Judges.—These were:—Class 1 to 12: Mr. Robert Parker, Exotic Nursery, Tooting, London; Mr. A. Roger, superintendent Battersea Park, London; and Mr. Carmichael, The Gardens, Crow Hall, Bath. Classes 13 to 37: Mr. T. Moore, Botanic Garden, Chelsea, London; Mr. C. Penny, The Gardens, Sandringham, King's Lynn; and Mr. R. H. Vertegan, Chad Valley, Edginton. Classes 38 to 53: Mr. D. T. Fish, The Gardens, Hardwick House, Bury St. Edmunds; Mr. J. Fleming, The Gardens, Clivedon, Maidenhead; and Mr. James Cutbush, The Nursery, Highgate, London. Classes 54 to 65: Mr. Shirley Hibberd, Stoke Newington, London; the Rev. S. R. Hole, Campton Manor, Newark; and the Rev. C. Peach, Appleton-le-Street, Malton. Classes 66 to 87: Mr. John Laing, Stanstead Park, Forest Hill, London; Mr. J. F. Meston, Haverstock Hill, London; and Mr. John Standish, Royal Nurseries, Asot. Classes 88 to 109: Mr. Thomas Bailey, the Gardens, Shardeoles, Armistlaw; Mr. A. F. Barron, Royal Horticultural Society, Chiswick, London; and Mr. E. Bennett, The Gardens, Hatfield House, Herts. Classes 110 to 130: Mr. Peter Barr, King Street, Covent Garden, London; Mr. J. Pottle, Sadborne Hall Gardens, Wickham Market; and Mr. J. McKirdy, Woodbine Lodge, Beckenham. The arrangement of the show was entrusted to Mr. Baines, of Southgate, and Mr. Spinks, Mr. Quilter's foreman.

LIST OF AWARDS.

DIVISION I.—PLANTS.

Sixteen Stove and Greenhouse plants, in bloom—1st prize, £25, E. Cole and Sons, Withington, near Manchester; 2nd, £18, Mr. Cypher, Queen's Road, Cheltenham; 3rd, £12, Mr. Marsh, gardener to Mr. J. O. Baehus, Binswood, Leamington; a silver challenge cup, of the value of 25 guineas, in addition to the money prize, E. Cole and Sons.

Ten Stove and Greenhouse plants, in bloom, nurserymen—1st prize, £15, E. Cole and Sons; 2nd, £10, Mr. F. Perkins, Leamington; 3rd, £7, Mr. Cypher.

Ten Stove and Greenhouse plants, in bloom, amateurs—1st prize, £15, Mr. Chapman, Rugeley; 2nd, £10, Mr. Chadwick, gardener to Mr. C. Nelson, Crackley Hill, Kenilworth.

Specimen Stove plant, in bloom—1st prize, £1 10s., Mr. Webb, gardener to Mr. J. Gimson, Stoke, Coventry, and E. Cole and Sons, equal; 2nd, £1, Mr. B. S. Williams; 3rd, 15s., Mr. Chadwick.

Specimen Greenhouse plant, in bloom—1st prize, £1 10s., Mr. B. S. Williams; 2nd, £1, Mr. Parker, Rugeley; 3rd, 15s., Mr. Chadwick.

Nine Fine-foliated Plants, nurserymen—1st prize, £10, Cole and Sons; 2nd, £7, Mr. B. S. Williams; 3rd, £5, Mr. Heath, Cheltenham; Mr. Pilgrim and Mr. Dixon (extra).

Nine Fine-foliated Plants, amateurs—1st prize, £10, Mr. T. M. Shuttleworth; 2nd, £7, Mr. Forster; 3rd, 6s., Mr. Brown.

Six Fine-foliated Plants, nurserymen—1st prize, £5, Mr. Heath; 2nd, £3, not awarded; 3rd, £2, E. Cole & Son.

Six Fine-foliated Plants, amateurs—1st prize, £5, Mr. Marsh; 2nd, £3, Mr. Brown.

Specimen Fine-foliated Plant—1st prize, £1 10s., Mr. Heath; 2nd, £1, Mr. Croucher, gardener to Mr. J. T. Peacock, Hammersmith; 3rd, 15s., Mr. Beecher, gardener to Mr. L. Foster, Walsall.

Six Dracaenas (green varieties excluded)—1st prize, £4, Mr. Brown.

Specimen Croton—1st prize, £1 10s., E. Cole & Sons; 2nd, £1, Mr. Heath; 3rd, 15s., Mr. Chapman.

Eight Stove and Greenhouse Ferns, nurserymen—1st prize, £10, Mr. B. S. Williams; 2nd, £7, Mr. Cypher and Mr. T. M. Shuttleworth, equal; 3rd, £5, Mr. Pilgrim.

Eight Stove and Greenhouse Ferns, amateurs—1st prize, £10, Mr. Brown; £7, Mr. T. M. Shuttleworth, equal; no 2nd prize; 3rd, £5, Mr. Coleman.

One Tree Fern, nurserymen—1st prize, £2, Mr. B. S. Williams; 2nd, £1, Mr. Pilgrim; 3rd, 1s., Mr. Vertegan.

One Tree Fern, amateurs—1st prize, £2, Mr. Jones; 2nd, £1, Mr. Quarterman, gardener to Mr. W. T. Gladstone, Edginton.

Specimen Stove or Greenhouse Ferns (Adiantum excluded)—1st prize, £1 10s., Mr. B. S. Williams; 2nd, £1, Mr. Parker; 3rd, 15s., Mr. Shuttleworth.

Specimen Adiantum—1st prize, £1 10s., Mr. Cypher; 2nd, £1, Mr. Turner, Slough; 3rd, 15s., Messrs. Cole & Sons.

Six Lycopodiums—1st prize, £2, Mr. Webb; 2nd, £1 10s., Mr. Allen; 3rd, Mr. Jones.

Twelve Hardy Ferns—1st prize, £4, Mr. Mapplebeck, Macclesfield; 2nd, £3, Mr. Pilgrim; 3rd, £2, Messrs. Ivery & Son, Dorking.

Three Pitcher Plants—1st prize, £7, Mr. Shuttleworth; 2nd, £4, Mr. B. S. Williams.

Specimen Pitcher Plants—1st prize, £1 10s., Mr. B. S. Williams; 2nd, £1, Mr. Shuttleworth.

Six Erihas, nurserymen—1st prize, £6, Mr. Dixon; 2nd, £4, Mr. Cypher.

Six Erihas, amateurs—1st prize, £6, Mr. Chapman.

Specimen Erihas—1st prize, £1 10s., Messrs. Cole & Sons; 2nd, 15s., Mr. B. S. Williams; 3rd, 15s., Mr. Foster.

Six Palms—1st prize, £7, Mr. B. S. Williams; 2nd, 17s., Mr. Leacock; 3rd, 27s., Messrs. Felton & Sons and Mr. Marsh, equal.

Six Palms in 5-inch Pots—1st prize, 37s., Messrs. Felton & Sons; 2nd, 27s., Mr. R. H. Vertegan; 3rd, 17s., Mr. Pilgrim.

Six New Plants, in or out of flower (Orchids excluded)—1st prize, £5, Mr. B. S. Williams; 2nd, £3, Mr. Cypher; 3rd, £2, Messrs. Felton & Sons.

Six New and Rare Plants, sent out in 1872, 1873, or 1874, in or out of flower—1st prize, £5, Mr. B. S. Williams; 2nd, £3, Mr. Dixon; 3rd, £2, Mr. Piersdorff.

Ten Orchids—1st prize, £12, Mr. B. S. Williams; 2nd, £9, Mr. Mitchell, gardener to Dr. Ainsworth, Broughton, Manchester.

Six Orchids, nurserymen—1st prize, £6, Mr. B. S. Williams.

Six Orchids, amateurs—1st prize, £9, Mr. Mitchell; 2nd, £1, Mr. Williamson, Ramsdale Hall, Lawton, Cheshire.

Specimen Orchid—1st prize, £1 10s., Mr. B. S. Williams.

Nine Gloxinias—1st prize, £1 10s., Mr. Allen.

Twelve Agaves—1st prize, £6, Mr. J. Croucher; 2nd, £4, Mr. Piersdorff; 3rd, £2, Mr. Pilgrim.

Collection of Twenty-five Cacti—1st prize, £3, Mr. Croucher; 2nd, £4, Mr. Piersdorff.

Collection of Twenty-five Succulents (Cacti and Agaves excluded)—1st prize, £6, Mr. J. Croucher; 2nd, £4, Mr. Piersdorff; 3rd, £2, Mr. Pilgrim.

Ten Clematis—1st prize, £7, Messrs. Jackman & Son, Woking; 2nd, £5, Mr. Vertegan.

Six Pots of *Lilium auratum*—1st prize, £4, not awarded; 2nd, £3, not awarded; 3rd, £2, Mr. Turner.

Nine Fuchsias—1st prize, £5, Mr. Caldicott; 2nd, £3, Mr. Harborne, Smethwick; 3rd, £2, Mr. Coleman.

Four Fuchsias—1st prize, £2 10s., Mr. Cox, gardener to Earl Beauchamp; 2nd, £1 10s., Mrs. Brown, Rugby; 3rd, £1, Mr. Harborne.

Specimen Fuchsia—1st prize, £1, Mr. Harborne; 2nd, 15s., Mr. Caldicott; 3rd, 15s., Mr. Coleman.

Nine Show Pelargoniums—1st prize, £5, Mr. Turner; 2nd, £3, Mr. Quarterman; 3rd, £2, Mr. Marsh.

Six Show Pelargoniums—1st prize, £3, Mr. Turner; 2nd, £2, Mr. Quarterman; 3rd, £1, Mr. Allen.

Collection of Twenty Show Pelargoniums, not less than twelve varieties—1st prize, £5, Mr. Turner; 2nd, £3, not awarded; 3rd, £2, Mr. Chadwick.

Six Fancy Pelargoniums—1st prize, £3, Mr. Quarterman; 2nd, £2, Mr. Turner; 3rd, £1, Mr. Coleman.

Nine Zonal Pelargoniums—1st prize, £5, Mr. Marsh; 2nd, £3, Mr. Cox; 3rd, £2, Mr. Quarterman.

Six Nosegay or Hybrid Nosegay Pelargoniums—1st prize, £3, Mr. Turner; 2nd, £2, Mr. Quarterman.

Six Tricolor Pelargoniums, gold or silver-edged—1st prize, £3, Mr. Ford; 2nd, £2, Mr. Marsh; 3rd, £1, Mr. Turner.

Six Gold and Bronze Pelargoniums—1st prize, £1 10s., Mr. Allen; 2nd, £1, Mr. Newton; 3rd, 15s., Mr. Cox.

Six Double Pelargoniums—1st prize, £2, Mr. Parker.

DIVISION 2.—ROSES AND OTHER CUT FLOWERS

Seventy-two Roses, single trusses, nurserymen—1st prize, £10, Messrs. Paul and Son; 2nd, £5, Mr. Cant; 3rd, £5, Mr. Cranston; 4th, £3, Messrs. Perkins; a silver challenge cup, of the value of 25 guineas, offered in addition to the money prize—Messrs. Paul and Son.

Forty-eight Roses, three trusses each, nurserymen—1st prize, £4, Messrs. Paul and Son; 2nd, £4, Mr. Cranston; 3rd, £3, Mr. Keynes; 4th, £2, Mr. Turner.

Twenty-four Roses, Hybrid Perpetuals only, three trusses of each, nurserymen—1st prize, £1, Messrs. Paul and Son; 2nd, £3, Mr. Cant; 3rd, £2, Mr. Prince, Oxford; 4th, £1, Messrs. Perkins and Son.

Twenty-four Roses, single trusses, nurserymen—1st prize, £3, Mr. Menweather; 2nd, £2, Mr. Cass; 3rd, £1, Mr. Prince; 4th, 10s., Mr. Turner.

Forty-eight Roses, single trusses, amateurs—1st prize, £6, Mr. State, gardener to the Rev. C. Evans, Solihull; 2nd, £4, Mr. Draycott, gardener to Sir B. Chetwode, Bart., 11 Clifton Hill, Leicester; 3rd, £3, Rev. G. Arkwright, Pencombe, Hereford; 4th, £2, Mr. Draycott, a silver challenge cup, of the value of 25 guineas, in addition to the money prize—Mr. State.

Thirty-six Roses, single trusses, amateurs—1st prize, £5, Mr. Evans; 2nd, £3, Mr. Parnell; 3rd, £2, Mr. Paget.

Twenty-four Roses, single trusses, amateurs—1st prize, £4, Mr. Mayo, Oxford; 2nd, £3, Mr. Parnell; 3rd, £2, Mr. Evans; 4th, £1, Mr. Fowkes.

Twelve Roses, single trusses—1st prize, 2l., Mr. Brown; 2nd, 1l. 10s., Mr. Parnell; 3rd, 1l., Mr. Evans; 4th, 10s., Mr. State.

Twelve Roses of 1871, 1872, or 1873, single trusses—1st prize, 2l., Messrs. Paul & Son; 2nd, 1l. 10s., Mr. Cranston; 3rd, 1l., Mr. Howes; 4th, 15s., Mr. Cant.

Six Trusses of any Rose of 1871, 1872, or 1873—1st prize, 1l., Mr. Cranston; 2nd, 15s., Messrs. Paul & Son; 3rd, 10s., Mr. Cant; 4th, 7s., Mr. Laxton.

Twelve Tea-scented and Noisette Roses, single trusses, nurserymen—1st prize, 1l. 10s., Mr. Cant; 2nd, 1l., Messrs. Paul & Son; 3rd, 15s., Mr. Prince.

Twelve Tea-scented and Noisette Roses, single trusses, amateurs—1st prize, 2l., Mr. Evans; 2nd, 1l. 10s., Rev. G. Arkwright; 3rd, 1l., Mr. Laxton.

Twelve Roses, single blooms—1st prize, 1l. 10s., Mr. Turner.

Twenty-four Roses, in not fewer than twelve varieties, grown in pots not exceeding eight inches in diameter—1st prize, 6l., Mr. Whiteinan; 2nd, 1l., Mr. Cooling.

Twelve trusses of H. P. Alfred Colomb—1st prize, 1l., Mr. Turner; 2nd, 15s., Mr. Cant.

Twelve trusses of H. P. Duke of Edinburgh—1st prize, 1l., Mr. Turner; 2nd, 15s., Mr. Cant.

Twelve trusses of H. P. Baroness Rothschild—1st prize, 1l., Mr. Cant; 2nd, 15s., Messrs. Paul & Son.

Twelve trusses of H. P. La France—1st prize, 1l., Mr. Cant.

Twelve Trusses of H. P. Marie Baumann—1st prize, 1l., Mr. Prince; 2nd, 15s., Messrs. Paul & Son.

Twelve Trusses of Noisette Marchal Niel—1st prize, 1l., Mr. Cant; 2nd, 15s., Rev. W. H. Benn.

Twelve Trusses of Tea Devonians—1st prize, 1l., Mr. Cant; 2nd, 15s., Mr. Way, Jesus College, Oxford.

One Vase of Roses, cut blooms, set up with Rose foliage only—1st prize, 1l., Messrs. Perkins; 2nd, 15s., Mr. Chard.

Eighteen Bunches of Cut Flowers, nurserymen—1st prize, 1l., Cole & Sons; 2nd, 3l., Messrs. Perkins.

Eighteen Bunches of Cut Flowers, amateurs—1st prize, 1l., Mr. Chapman; 2nd, 3l., Mr. Milton, Manchester; 3rd, 2l., Mr. Chadwick.

Eighteen Bunches of Hardy Border Flowers—1st prize, 2l., Messrs. Perkins.

Twelve Carnations (selfs excluded)—1st prize, 1l. 10s., Mr. Turner; 2nd, 1l., Mr. Hooper; 3rd, 10s., Mr. Catley.

Twelve Self Carnations—1st prize, 1l., Mr. Turner; 2nd, 15s., Mr. Catley; 3rd, 10s., Mr. Hooper.

Twelve Picotees—1st prize, 1l. 10s., Mr. Turner; 2nd, 1l., Mr. Hooper; 3rd, 10s., Mr. Catley.

Twelve Pinks—1st prize, 1l. 10s., Mr. Turner; 2nd, 1l., Mr. Brown; 3rd, 10s., Mr. Hooper.

One Bridal Bouquet—1st prize, 2l., Messrs. Perkins; 2nd, 1l. 10s., Mr. Turner, Liverpool; 3rd, 1l., Messrs. Felton & Son.

One Ball or Opera Bouquet—1st prize, 2l., Messrs. Perkins; 2nd, 1l. 10s., Mr. Jones; 3rd, 1l., Mr. Jackson.

Three Pieces for Table Decoration (fruit excluded)—1st prize, 6l., Mr. Cooke; 2nd, 5l., Mr. Jackson; 3rd, 1l., Mr. Smith, gardener to Mr. C. N. Newdegate, M.P.; 4th, 3l., Mr. Cypher.

Gentlemen's Button-hole—1st prize, 15s., Messrs. Pope & Son; 2nd, 10s., Miss Laines, Soutgate; 3rd, 7s., Mr. Turner; 4th, 5s., Mr. Cypher.

DIVISION III.—FRUIT.

Two Queen Pine Apples—1st prize, 2l., Mr. Harris, Singleton Gardens, Swansea; 2nd, 1l. 10s., Mr. Bond, gardener to Mr. G. A. Smith, Weybridge; 3rd, 15s., Mr. Sandford, gardener to the Beehive, Kerby Lonsdale, Westmoreland.

Two Smooth Cayenne Pine Apple—1st prize, 2l., Mr. Wilson.

One Pine Apple, any other variety—1st prize, 1l., Mr. Bruce.

Six Pine Apples, not necessarily distinct—1st prize, 5l., Mr. Harris; 2nd, 4l., Mr. Bond; 3rd, 3l., Mr. Wilson; 4th, 2l., Mr. Miles.

Three Bunches of Black Hamburgh Grapes—1st prize, 3l., Mr. Coleman; 2nd, 2l., Mr. Fleming; 3rd, 1l., Mr. Douglas, Ralford, Notts.

Three Bunches of Black Grapes, any other variety—1st prize, 3l., Mr. Sweeting; 2nd, 2l., Mr. M. Henderson.

Three Bunches of Muscat or Black Alexandria Grapes—1st prize, 3l., Mr. Foster; 2nd, 2l., Mr. Cox; 3rd, 1l., Mr. Haynes.

Three Bunches of Buckland Sweetwater Grapes—1st prize, 3l., Mr. Cox; 2nd, 1l. 10s., Mr. Douglas; 3rd, 1l., Mr. Coulson.

Three Bunches of White Grapes, any other variety—1st prize, 2l., Mr. Douglas; 2nd, 1l. 10s., Mr. Coleman; 3rd, 1l., Messrs. Stoddish and Co., Acon.

Collection of six varieties of Grapes, single bunches—1st prize, 5l., Mr. Douglas; 2nd, 3l., Mr. Henderson; 3rd, 2l., Mr. Baumann.

Six Peaches, any variety—1st prize, 1l. 10s., Mr. Miles; 2nd, 1l., Mr. Baumann; 3rd, 15s., Mr. Jackson; extra, Mr. Coleman.

Six Nectarines, any variety—1st prize, 1l. 10s., Mr. Haynes; 2nd, 1l., Mr. Baumann and Mr. Coleman; 3rd, 15s., Mr. Henderson.

Eight Apples, any variety—1st prize, 1l., Mr. Smith; 2nd, 15s., Mr. Winston, gardener to Mr. H. B. Preston, Kenilworth.

Twelve Pigs, any variety—1st prize, 1l., Mr. Baumann; 2nd, 15s., Mr. Foster.

Fifty Black Cherries, any variety—1st prize, Mr. Miles; 2nd, 15s., Mr. Barnwell; 3rd, 10s., Mr. Gardner.

Fifty White Cherries, any variety—1st prize, 1l., Mr. Miles; 2nd, 15s., Mr. Douglas; 3rd, 10s., Mr. Miles.

Twenty-five Strawberries, of the British Queen or Dr. Hogg type, one variety—1st prize, 1l., Mr. Cox; 2nd, 15s., Mr. Gardner; 3rd, 10s., Mr. Taylor.

Twenty-five Strawberries, any other variety—1st prize, 1l., Mr. James; 2nd, 15s., Mr. Chadwick; 3rd, 10s., Mr. Taylor.

One Melon, Green-fleshed—1st prize, 1l., Mr. Cox; 2nd, 15s., Mr. Nott; 3rd, 10s., Mr. Gardner.

One Melon, Scarlet-fleshed—1st prize, 1l., Mr. Read; 2nd, 15s., Mr. Maledin; 3rd, 10s., Mr. Coleman.

Collection of Eight Dishes of Fruits, to contain not more than Two Dishes of Grapes—1st prize, 10l., Mr. Coleman; 2nd, 7l., Mr. Baumann; 3rd, 5l., Mr. Goodacre.

DIVISION IV.—VEGETABLES.

Collection of Ten Dishes of Vegetables (Cucumber and Salading excluded)—1st prize, 5l., Mr. Miles; 2nd, 3l., Mr. Turk; 3rd, 2l., Mr. Holder; a Silver Cup, of the value of 25 guineas, in addition to the money prizes in the preceding class—Mr. Miles.

Collection of Eight Dishes of Vegetables (Cucumber and Salading excluded)—1st prize, 3l., Mr. Arkell, gardener to Mr. A. G. Skinner, Cueltenham; 2nd, 2l., Mr. Ford; 3rd, 1l., Mr. Barnett.

Three Dishes of Kidney Potatoes, twelve tubers of each—1st prize, 1l. 10s., Mr. Baker; 2nd, 1l., Mr. Biddles, Loughborough; 3rd, 10s., Mr. Bagerley.

Three Dishes of Round Potatoes, twelve tubers of each—1st prize, 1l. 10s., Mr. Baker; 2nd, 1l., Mr. Gilbert; 3rd, 10s., Mr. Bagerley.

One Dish of Twelve Kidney Potatoes, one variety—1st prize, 10s., Mr. Biddles; 2nd, 7s., Mr. Miles; 3rd, 5s., Mr. Bagerley.

One Dish of Twelve Round Potatoes, one variety—1st prize, 10s., Mr. Biddles; 2nd, 7s., Mr. Craddock; 3rd, 5s., Mr. Baker.

Three Varieties of Peas, half a peck of each—1st prize, 1l. 10s., Mr. Gilbert; 2nd, 1l., Mr. Richardson; 3rd, 10s., Mr. Cox and Mr. Turk, equal.

One Dish of Peas, half a peck, one variety—1st prize, 15s., Mr. Miles; 2nd, 10s., Mr. Baker; 3rd, 5s., Mr. Dean.

One Dish of Twelve Onions, one variety—1st prize, 10s., Mr. Smith; 2nd, 7s., Mr. Turk; 3rd, 5s., Mr. Arkell.

One Brace of Cucumbers—1st prize, 15s., Mr. Douglas; 2nd, 10s., Mr. Holden; 3rd, 5s., Mr. Chadwick.

One Dish of French Beans, fifty pods, one variety—1st prize, 15s., Mr. Miles; 2nd, 10s., Mr. Wilson; 3rd, 5s., Mr. Day.

Three Sticks of Celery—1st prize, 15s., Mr. Arkell; 2nd, 10s., Mr. Smith; 3rd, 5s., Mr. Bloxham, Bletchley.

Three Sticks of Rhubarb—1st prize, 15s., Mr. Smith; 2nd, 10s., Mr. Cox; 3rd, 5s., Mr. Mitchell.

One Dish of Twelve Carrots, one variety—1st prize, 10s., Mr. Arkell; 2nd, 7s., Mr. Smith; 3rd, 5s., Mr. Baker.

One Dish of Twelve Turnips, one variety—1st prize, 7s., Mr. Holder; 2nd, 5s., Mr. Douglas; 3rd, 3s., Mr. Barnwell.

Three Cabbages, one variety—1st prize, 5s., Mr. Ford; 2nd, 3s., Mr. Arkell; 3rd, 2s., Mr. Brown.

Three Cabbage Lettices, one variety—1st prize, 5s., Mr. Brown; 2nd, 3s., Mr. A. Dean; 3rd, 2s., Mr. Allen.

Three Cauliflowers, one variety—1st prize, 10s., Mr. Barnwell; 2nd, 7s., Mr. Ford; 3rd, 5s., Mr. Miles.

Bunch of Thirty Heads of Asparagus—1st prize, 10s., Mr. Arkell; 2nd, 7s., Mr. Smith; 3rd, 5s., Mr. Turk.

One Dish of Thirty Broad Beans—1st prize, 7s., Mr. Miles; 2nd, 5s., Mr. Richardson.

Basket or Tray of Salads, not less than twelve varieties—1st prize, 1l. 10s., Mr. Smith; 2nd, 1l., Mr. Holden; 3rd, 15s., Mr. Turk.

One Dish of Twelve Mushrooms—1st prize, 10s., Mr. Cushman; 2nd, 7s., Mr. Allen; 3rd, 5s., Mr. Holder.

One Dish of Twelve Tomatoes—1st prize, 15s., Mr. Cox; 2nd, 10s., Mr. Miles; 3rd, 5s., Mr. Arkell.

Special prizes offered by Mr. Thomas Laxton, Stamford, for any four of the following varieties of new Peas, raised by himself, and distributed by Messrs. Harst, Leadenhall Street, viz., Laxton's No. 1, Full-basket, Speculative, William the First, Omega, and Popular, Fifty Pods each—1st prize, 4l., "not known"; 2nd, 2l. 10s., Mr. Gilbert; 3rd, 1l., Mr. Miles.

COVENT GARDEN MARKET.

JULY FURN.

This market is still well supplied, and the bustle of the fruit season is now commencing in earnest. All kinds of small fruits, as Gooseberries, Currants, Strawberries, Raspberries and Cherries are abundant and cheap. Now is the time to obtain the above for preserving, as the two latter kinds more especially will never be cheaper or fresher than at present. Among dessert fruit, Grapes, Figs, Melons, Pines, and Peaches, are of unexceptionally fine quality. West Indian Pines are now plentiful, two large variegated having recently come to hand in splendid condition. Vegetables are fresh and plentiful. Cucumbers and small Saladings are now in excellent condition. Tomatoes, principally imported fruit, are abundant and of excellent quality. Among cut flowers, Stephanotis, Roses, Bonnyard, Heliotrope, Waterlilies, Tuberoses, Pinks, Carnations, Double Pelargoniums, and Corn-flowers, make up the principal supply. Plants in pots consist of Pelargoniums, Fuchsias, and other ordinary flowering plants. Foliage plants, as Ficus elastica (the common India-rubber plant), Isoplepis gracilis, small Palms, Ferns, and Peacocks, and the graceful Umbrella Sedge are much a feature, and sell in large quantities for room, window, and balcony decoration.

Cut Flowers.

	s. d.	s. d.
Calla blooms, per doz.	3	0 to 9
Carnations, per doz. bunches	4	0 to 6

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

FLOWERS FOR THE BLIND.

It is more than a year since I made some remarks on "Flowers for the Sick and the Poor," and the "Flower Mission" is now a regularly organised system in this and other towns (*vide* Miss Stanley's paper in *Macmillan's Magazine* for April last). Still, I have not observed any particular notice of the blind; and for this past year, we have taken our supplies regularly to the Royal Blind Asylum, the manager informing me that no one had, as yet, thought of sending them flowers; and very much pleasure have we given during these twelve months to the inmates of that institution. Of course, for such an object, the supplies are limited to aromatic and sweet-smelling plants, of which at present there is abundance—Roses, Pinks, Stocks, Honeysuckles, and woody plants, Sweetbriar, Southernwood, Walnut; but the dry season has never let our herb beds grow, and we have had to fall back upon our winter Thyme and Rosemary, this last being the most unfailing and surest for all seasons and weathers. A hedge should be formed of it in gardens that are intended to regularly supply the blind, sick, and poor, also one of Sweetbriar; we had the border forked and loosened about the Sweetbriar, and gave it a thorough soaking; the Rosemary, on the other hand, which backs a succulent border, is enjoying the hot sun, and gives no trouble. I will name some plants that have given the blind pleasure, and which may not occur to those who have not tried, and succeeded in making a variety in their supplies every week in the year, to those deprived of the sense of sight; also the various shifts I have been put to, and the assistance I have had. There must always be a difficulty in supplying a sufficient quantity of any particular thing at the scarcest season, when one is dealing with a large or even a small public institution. For instance, it is not fair to go into a workroom containing eighteen or twenty blind workers, with only a dozen Narcissus, Polyanthus, or Hyacinths; and yet that number will, probably, clear off the whole supply of an ordinary greenhouse for one week. Our worst time occurred when the Snowdrops were over, and before sufficient Primulas of all sorts had come on (Violets, Primroses, Lily of the Valley later on, and Jessamine last of all, were four plants we could not attempt at all), and for two or three weeks, we were reduced to Sweet Bay, Rosemary, Lavender, and Thyme. One is often startled by such remarks and questions, from the blind, as these, "I saw Crocuses yesterday, but they have no smell. Snowdrops are sweet!" and "What is the colour of the flower?" At the time of the Duke of Edinburgh's marriage, they had all been out to "see" the illuminations, and were eloquent in their descriptions of what they liked best, one admiring the castle most, another a bank, or church. On applying to our two principal nurserymen I was at once most liberally supplied (one week from each) with sufficient Hyacinths and Lily of the Valley to go round the room we usually visit, and the workers in which were highly delighted, each sniffing at a fine Hyacinth and carefully going over every bell with their fingers (they always touch before they smell). The Lily of the Valley was an immense treat; all knew it by name and idea. Forced flowers for an asylum are quite out of the question, and, only at a pinch, can one ask nurserymen for them. I bethought me then of Balsam Poplar, any quantity of which I was allowed to cut in a neighbouring tree nursery. They liked the smell, but not the sticky feel to their fingers. From the moors also, I brought with me a quantity of the flowering branches of Bog Myrtle (*Myrica Gale*), which is deliciously fragrant (even more so than the leaves), and which conveniently came into bud at the scarce season; and here let me observe, for those who have eyes, the expanding of Gale flower buds in water is worth watching. Willow catkins they were delighted with, and, of the four varieties I took, at once selected the softest of them to feel over and over (velvet they were likened to), and, as they knew something about Willows, they were much interested and surprised to feel and learn that Willows had flowers. One poor woman's face lighted up, as she exclaimed, that she "did not know what they were, but she had pulled them when a girl." The Edinburgh Blind Asylum is passed by all the market carts coming from the south side of the city, and I suggested to one or two of the market gardeners, that unsold bunches of flowers or sweet herbs might be left at the asylum as they returned home. They were pleased with the idea, but I have not yet heard that any have been left—perhaps, on account of fresh unsold bunches of sweet herbs in summer being dried, and which are sure to sell in winter. It is wonderful how often, kindly well-meaning people have to be asked for and reminded of a little kindness they are perfectly

willing to give or to do; but, I quite own, from experience, that the flower, or gift, is the smallest and easiest part of the kindness. The time, trouble, thought, and punctuality, are the serious strain, and what people weary of after the first pleasant burst of feeling has evaporated, the sick, poor, and blind particularly (the latter never get better), are sure not to pass away from amongst us, and they remember the flower day with the precision of a chronometer. The only argument I have heard against "wasting flowers on the blind," was this, that a bottle of perfume would last much longer and go farther among them, and keep the flowers for the seeing sick and poor." Now, I hope this opinion will not weigh with any one who for a moment considers that the blind are deprived of the sense by which we all learn most of Nature; and, to compare a flower, pure and fresh from a field or garden, with the meritorious, but meretricious bouquets of Rimmel, is an impossibility. Then the great proportion of those in the Edinburgh Asylum have become blind (only one woman and four boys having been born so), and, therefore, have recollections of green leaves and bright flowers; and how pleased they all were to tell me that their Musk plants were growing, and their bits of Spearmint had got roots. The best arranged and ventilated work-rooms in any institution must be benefited by large basketfuls of aromatic herbs being emptied out in their midst, the atmosphere becoming purified thereby; and I am sure so must the health of each worker, who has a sprig of Thyme or Rosemary stuck in their dress to breathe over. Every public institution has its most convenient days and hours for receiving flowers. At the Blind Asylum Saturday forenoon is the best time, as they leave work early, and of course have Sunday to themselves. Cut flowers go farther in supplying the blind, because one sprig smells as sweet as a dozen; and they feel over the shape of one Hyacinth or Stock better than when a handful is given to them. From the delicacy of their touch, they can pick off any fading leaves or flowers on a spike, thus saving the donor's time. I tell them I bring them the flowers to sort and clean for themselves, not as if they were infirm patients, with hardly strength to smell the flowers laid by their side, as is often the case. I hope these remarks may remind any who have as yet overlooked the blind, that although those may be in fair health, and not in want, yet still flowers can cheer and elevate them, as well as other afflicted ones. The blind are true incurables. It seems superfluous to give a list of sweet-smelling plants suitable particularly for the object of this paper, but, at the risk of being tedious, I do so, having seen the pleasure they gave to those who can only smell and touch flowers.—*Rosemary, different sorts of **Thyme, Sweet Bay, different sorts of Arborvitæ, Rhododendron hirsutum, Gale (flowers for winter, leaves for summer), Lavender, *Southernwood, three sorts Artemisia, Spearmint, *Musk, Balm, Costmary, Sweetbriar, Woodruff, Mints (Nepeta, Melissa, Teucrium, Mentha, Origanum), Pot-herbs (usually so called), Balsam Poplar, Walnut (leaves), Willow (catkins), Myrtle, Gum Cistus, Balm of Gilead, Sweet Verbena, scented Geraniums (particularly *Odoratissimum*, Nutmeg, Lobatum and Peppermint scented, as they loved the soft, downy feel of these leaves), Heliotrope, Eucalyptus leaves, *Christmas Roses (*Helleborus niger*), *Snowdrops, Laurustinus, Arabis, *Wallflower, *Ribes, *Cocksies and Polyanthus, *Lilac, Hawthorn, Narcissus (particularly *Poeticus*), Hyacinth, *Syringa (Philadelphus), Buddlea globosa, *Roses (particularly Scotch and Cabbage), *Pinks (particularly double-white), *Stocks, Honeysuckle, Marigold (common yellow), Azalea, Daphne (Spurge Laurel), *Lily of the Valley, Day Lilies, Lilies (*Lilium candidum*), Mignonette, Sweet Peas, Lupins (common yellow), Carnations, Chrysanthemums (they liked the fresh smell of the leaves), and Salvia (*Grahamii*). The names with the * were decidedly the favourites, and we supplied rooted plants of those marked **. When frost sets in and plants have to be lifted, there is always a great waste of sweet leaves, which might be advantageously sent to institutions of the blind.

Wardie Lodge, Edinburgh, July 6.

F. J. HOPE.

The Fountains in Trafalgar Square.—As we write men are employed in breaking up and carting away the network of pipes which supplied the numerous water-squirts in one of the large fountain basins in Trafalgar Square. What changes or repairs are contemplated we know not, but one cannot see all this expensive fooling without regretting that (if we must suffer it and pay for it), it is not carried on in some out of the way nook in the parks. It is a pity to see a fine central space like Trafalgar Square despoiled by such "ornamentation." The open and precious space devoted to the wide and usually filthy fountain basins and extensive arid asphalt pavements, could of course be easily converted into a pretty garden, varied with trees, which would make the square charming to look upon, from the terraces above, and indeed from every point of view.

NOTES OF THE WEEK.

— THE unusual heat of the past week has advanced fruits considerably, but not always improved them. The great heats following heavy rains have improved the flavour of the Strawberries. Raspberries have come and gone before the heat more rapidly than ever has been known in Covent Garden. Fair Jargonelle Pears have come from France during the week, and also some Apples of an inferior class. Reine Claude Plums have come from Avignon. Tomatoes are poor and scarce. Flowers have been much forwarded by the heat; but they endure a shorter time than usual in the cut state.

— FRUIT of *Musa Champna*, a variety introduced to Syon from Trinidad, was shown at South Kensington the other day by Mr. Woodbridge, and pronounced to be remarkably rich in flavour, far superior in that respect to the ordinary kinds. The best flavoured of all the varieties of Banana grown in the tropics are of a pale rose colour; and it would be interesting to know if this colour is peculiar to a distinct variety, or whether it is merely due to favourable circumstances of growth.

— IN order to encourage a taste for horticulture among the young, the Royal Horticultural Society has caused a number of bronze medals to be struck, for presentation among successful exhibitors at the flower show of St. Botolph's, Bishopsgate, which has been long so ably conducted by the Rev. W. Rogers. This is doubtless a step in the right direction, and let us hope that the "Lindley Medal," awarded on more than one occasion, may also be struck and forwarded to those to whom it has been awarded.

— MESSRS. DOWNE, LAIRD, & LAING have, it is reported, discovered a specific against the ravages of the Hollyhock disease (*Puccinia malvacearum*). In allusion to this subject, our attention has been called to some Hollyhocks growing in the kitchen gardens at Moor Park. These, when about half-grown, were attacked very virulently by this Fungus, nearly every leaf being destroyed by it. The disease, however, appeared to die out as suddenly as it came; young foliage pushed forth as fresh and healthy as ever; and, when we last saw them, they promised a good show of bloom.

— WE have throughout fought against the practice of placing costly fountains in our gardens, public or private, as being an objectionable way of allowing architects and sculptors to fritter away moneys which ought to be devoted to pure horticulture. The last water-squirting arrangement, that around the feet of Shakespeare in Leicester Square is, however, the most puerile and lackadaisical thing ever perpetrated. So we say again to all who seek for natural beauty and quiet grace in a garden, avoid the "garden architect," who offers you stone and water jets instead of Grass and trees, and flowers and peace.

— THOSE interested about the hardness of the Fever-Gum tree (*Eucalyptus globulus*) will be glad to learn that it not only will grow in England, but that as far north as Fife-shire it will survive and even attain a considerable height. There is at Balmuto a tree of it about 30 feet high, growing against the residence of the well-known botanist Dr. Boswell Syme. Its age is upwards of twenty years; and, though nearly as high as the one at Powderham Castle (35 feet), it cannot, however, boast of the same girth (5 feet). It bears capsules each year, but the seeds do not ripen so far north.

— MR. G. F. WILSON, Heatherbank, Weybridge Heath, writes to us as follows:—" *Lilium californicum*, *L. Pardalinum*, and *L. puberulum* have bloomed well here planted out on the root-work and in beds. *L. Pardalinum* is most like *L. puberulum* in form, but has larger shoots and brighter scarlet on the tips of the petals; while the Lily brought by Mr. Robinson from California, and first named *L. Robinsoni*, but since considered as identical with *L. Pardalinum*, appears in every specimen I have bloomed to be at least an improved variety of this last, as the scarlet tips of the petals are much brighter, and as it is altogether a handsomer Lily. *L. Martagon dalmaticum*, with its fine head of rich purple flowers, has been much admired."

— THE Council of the Meteorological Society recently resolved to organise a system of observations of natural phenomena connected with the season, as well as of such branches of inquiry as tend to establish a connection between meteorological phenomena and vegetation. As a preliminary to carrying out this intention, they invited the various societies before which such subjects most naturally come, to nominate delegates to join a committee by whom the whole question, as bearing upon agriculture, horticulture, &c., should be considered, and to whom also any written communications should be submitted. The first meeting of this joint committee was held at the office of the society, 30, Great George Street, on Thursday, July 2, when delegates were present, and promises of co-operation read from the Royal Horticultural, Royal Botanic, Royal Agricultural, and other societies. After the subject had been fully discussed, the Rev. T. A. Preston, of Marlborough College, was requested to prepare

a list of plants to be observed, and also to draw up a report on the same. Other gentlemen were requested to prepare lists of insects, birds, and animals.

— THE prize Grapes grown by Mr. Colman at Eastnor Castle have been exhibited in Messrs. Webber's windows in Covent Garden for the past few days. The Hamburgh bunches have never been surpassed for beauty and finish.

— SIOKE NEWINGTON GREEN, which has long been in a disgraceful state, is shortly to be laid out as a public park, the Islington Vestry having resolved to purchase it from the Lord of the Manor of Highbury.

— WE have received the "Natural Principles of Landscape Gardening," by Mr. J. F. Johnson, Curator of the Royal Botanic Gardens, Belfast. It is published, for the author, by Messrs. Aitchison & Sons, Belfast. We shall take an early opportunity of reviewing the book.

— WE have received from Mr. Muir, of Clovenfords, blossoms of the very handsome *Mimulus maculosus*, naturalised in that neighbourhood. It is supposed to have been thrown from some garden into the river Caddon, and to have been deposited by that mountain streamlet in the places in which it is now found.

— A DRIED collection of new kinds of Peas was exhibited by Messrs. Carter & Co. at the last meeting of the Royal Horticultural Society, together with a very interesting collection of forty-five kinds of Lettuce, including all worth culture, as well as some singular and rarely-seen varieties of that tribe of plants.

— FOUR splendid Queen Pines were sent to the last meeting of the Royal Horticultural Society by Mr. Harris. These weighed collectively 19 lbs. 3 ozs., and were perfect in shape and colour, well swelled, and in every way really noble fruit. They were the best Queen Pines we have seen this season.

— THERE is now in Mr. Chater's nursery, at Saffron Walden, a plant of *Arundo conspicua*, bearing sixteen beautiful feather-like panicles of bloom. Though this plant has been out of doors four years in the most exposed part of the grounds, its growth is very vigorous, and, even when not in bloom, the plant is attractive, its graceful foliage being of the loveliest green.

— A PLANT of *Mandevilla suaveolens* at Battle Abbey, has been growing in the open air during the past fifteen years. Out flowers from it were shown at South Kensington on the 16th inst., and were as much admired for their pure white colour and elegant form, as for their delicate fragrance. It is one of the finest of all climbing plants for a cool conservatory.

— THE fine collection of Orchids belonging to Mr. J. Brand, of Balham, is, we learn, to be sold by auction next week. The collection contains some fine specimen *Phalenopsis*, *Angraecum sesquipedale*, *Epidendrum vitellinum majus*, and many other valuable plants, among which may be mentioned *Eucharis amazonica*, in the culture of which Mr. Howard has been so successful.

— WE understand that a committee of gentlemen are occupied in getting up a testimonial to Mr. John Gibson, late of Battersea and Hyde Park. We have, however, had no official intimation of any kind from the committee or from any of its members. Mr. John Gibson was the first to modify in this country the appalling display of scarlet and yellow in our gardens, and well deserves as good a "testimonial" as can be given him.

— MR. INGRAM, Belvoir Castle, Grantham, says:—"I do not remember such a bad season as this has been for spring transplants! plants. We were deficient 4½ inches of rain at the end of 1873; we are now minus 6 inches; this is 1,000 tons per acre less than our average for nine months."

— THE Caen Academy of Science and Art proposes as the subject of the Le Sauvage prize, of the value of 1,000 francs, to be awarded in 1876, the question of the "Function of leaves in the vegetation of plants." The academy does not want simply an exposition of the present state of science on this important question; it requires, besides, from competitors, exact experiments performed by themselves, and new facts tending to throw light upon, invalidate, confirm, or modify doubtful points in the theories at present accepted. The memoirs ought to be sent to the academy before 1st January, 1876.

— AT the Vienna Exhibition there were specimens of paper made from several materials which have not hitherto been utilised for that purpose. Among these was paper from the Mulberry-tree bark, from the Stinging Nettle, and from Potato stalks. In sections of European countries where Mulberry leaves are used for feeding silkworms the remaining twigs have served only for fuel. But now, in Austria and parts of Italy, the bark is peeled off by a very simple arrangement, and from it a material prepared, from which a good quality of paper is made. In Hungary the Nettle is used with rags for making fine sketching and copying paper, and in Bohemia wrapping paper is made from Potato stalks.

THE INDOOR GARDEN.

LADY'S-SLIPPERS.

(CYPRIPEDIUM.)

OF the different species belonging to this genus, all, both hardy and tender, are favourite garden plants. They are widely distributed in both hemispheres, and in all kinds of climates, from the north of Europe, and North and South America, to Japan, India, Borneo, Java, and the Philippines. In the whole family of Orchids, there is, perhaps, no other genus which has a wider range. Botanically, *Cypripediums* are distinguished by their having two fully-developed anthers, and the lateral sepals connate, or fused together, there being only one solitary exception in *C. arietinum*, whilst popularly they are readily known by their slipper-shaped lip. One tolerably well-marked section, all the species belonging to which being tropical American, has been made by the younger

Propagation.

All the species are stemless herbs, and are readily propagated by dividing strong established masses; such off-shoots soon make blooming plants. Several beautiful new hybrids have been raised by Mr. Dominy and Mr. Seden in the Royal Exotic Nursery, at Chelsea, and also by Mr. Cross, gardener to Lady Ashburton, at Melchet Park, in Hampshire, after whom one of the hybrids is named. Other cultivators, including Mr. Pileher, gardener to Sigismund Rucker, Esq., at Wandsworth, have raised seedlings from the chaste little *C. Schlimmii*, but these are said to vary but little from the parent plant. In order to obtain seed it is necessary to fertilise the stigmatic surface of one flower with the glutinous or honey-like pollen from another flower of the same plant, or from a separate species, if a hybrid is desired. The stigmatic surface in this genus is concealed by the infolded margins of the lip, and is, generally, a thick trowel-shaped ivory-like process just below

Hardy Varieties of Lady's-slipper.

Reichenbach, a separate genus—*Selenipedium*—but in the following remarks I have grouped all the species under the older and better-known name of *Cypripedium*. The different species of *Cypripediums* are nearly as diverse in habit and mode of growth as they are in their geographical distribution; all the hardy, and some of the tropical American tender kinds, are strictly terrestrial; others have been found clinging to the face of sunny limestone rocks in Moulmein and Burmah, while *C. Lowii* belongs to a group which is strictly epiphytal. The culture of all the tender species is by no means difficult, but that of the hardy North American and Siberian kinds is just the reverse, and many have failed to get such plants to bloom except during the first season, after they have been imported. The best results have been obtained with *C. spectabile*, *C. humile*, and *C. pubescens*, while Messrs. Backhouse have succeeded in flowering the rare and beautiful *C. guttatum* and *C. irapeanum* in their nursery at York, where a broad patch of the only British species, *C. Calceolus*, also does well on rock-work.

the broad shield-like sterile anther, or staminode. Press down the lip and apply the pollen to the under side with the point of a pencil, or a quill tooth-pick will serve admirably for this purpose. The seed resembles fine mahogany sawdust, and should be sown as soon as ripe on the surface of living *Sphagnum* Moss that has become thoroughly established on the surface of a pot of fibrous peat; cover partially with a bell-glass, tilting it at the bottom so as to allow a free circulation of air. This last precaution is especially necessary just when the young seedlings make their appearance, as that is the most critical period in their growth, and many thousands of seedling Orchids never get beyond that stage. As the seedlings develop themselves they may be removed and potted off separately, and treated as recommended for established plants.

Culture of Tender Species.

These should be potted in a fresh open compost consisting of fibrous peat broken into lumps about the size of pigeons'

eggs, with the fingers; to this add about one-fifth of either dried horse droppings or cow manure, which should be collected in pastures in summer when dry and laid on a hot flue long enough to kill all insect life that it might contain. A little turfy loam may also be added in the case of the most robust-growing species, adding sufficient coarse well-washed sand or grit to keep the whole porous. The pots or pans in which the plants are to be put should be well washed and thoroughly dry before they are used, and this remark also applies to the crocks employed for drainage. *Cypripediums* do not require so much drainage as many other *Orchids*; indeed, about one-third the depth of the pot or pan will be amply sufficient for them. Place a thin layer of fresh Moss, or the rough fibre from peat, over the crocks so as to prevent the finer particles of compost being washed down among the drainage. The collar of the plants may be about level with the rim of the pot, and the compost should be neatly surfaced with fresh Sphagnum, which should be kept regularly sprinkled with spray from a syringe so as to induce it to grow as freely as possible. All the species require a copious supply of moisture when growing, both overhead and at the root, and they should never be allowed to become dry, as they, like many other stemless *Orchids*, have no decided season of rest. During the spring, summer, and autumn months they should all be regularly syringed morning and evening; and, in exceptionally hot dry weather, a gentle dewing in the middle of the day will induce that healthy vigour and fresh succulent growth so pleasing to the eye of the practical cultivator. They should be shaded carefully from hot sunshine, and free ventilation is essential, care being taken to guard the more tender species from cold cutting draughts. All these plants are more or less liable to be attacked by insect pests, especially if out of health through any irregularity in their treatment. Thrips, red spider, and the yellow aphides peculiar to *Orchid*-houses must all be guarded against by means of a liberal use of the syringe and abundance of fresh air. If, however, thrips and fly have obtained a foothold, eradicate them at once by repeated fumigations with tobacco-cloth or rag. It is better to fumigate gently on two or three successive evenings than run the risk of burning the foliage by filling the house too full of hot smoke. If the plants are gently sponged over occasionally with clean tepid water it will do much towards keeping them free from dust and insects. Some recommend the use of weak liquid-manure when the plants are making their growth, but beginners had better avoid such applications. Many of the species grow well in a moderately warm greenhouse temperature or in a *Cattleya*-house, but *C. Stonei*, *C. levigatum*, *C. concolor*, *C. niveum*, and one or two others, do best in the warm moist atmosphere of a stove or East India house. The pretty little *C. Schlimmii* does best in a cool house with Disas and *Odontogloss*, and requires careful attention to prevent its suffering from thrips, which seem to have a special liking for its fresh succulent foliage.

Culture of Hardy Species.

This section is scarcely less beautiful than that containing the tropical species, from which the hardy kinds are readily distinguished by their herbaceous habit. One of the freest and most vigorous of the whole group is the white-flowered rosy-lipped *C. spectabile*; and *C. pubescens* and *C. humile* seem to do much better than any of the others, if we except *C. Calceolus*. The majority succeed tolerably well for a year or two in a cool moist peaty compost; and, if grown in pots, they should be plunged in a cold frame with a northern aspect, and protected from the mid-day sun. *C. spectabile* may be planted out in a border of peat and leaf-mould, where it will flower several years in succession if kept regularly moist and cool at the root. *C. Calceolus*, on the other hand, prefers a strong chalky loam, with an eastern aspect, sheltered on all sides from rough winds and sun. If these hardy *Lady's-slippers* are grown in pots, they should be well drained, as has just been recommended; and, if syringed every morning, so much the better. The pots should be surfaced with fresh green Sphagnum to prevent undue evaporation from the soil; and such surfacing also keeps the soil cool, by acting as a non-conductor. The roots should never be allowed to become dry, even in winter—an evil to which may be attributed, I fear, the

loss of many of these interesting plants. In 1842 a collection of these hardy species used to grow well in Messrs. Rollisson's nursery, at Tooting, planted in a peat border outside at the back of a *Heath-house*. During winter and spring they were protected by a layer of Sphagnum 2 to 3 inches in thickness.

I now propose to furnish a simple key to the species, and to add such descriptive details as may prove of use to cultivators:—

I. *Cypripedium*.

HARDY OR TENDER.—Species, mostly herbaceous; flower-stems, leafy; leaves, thin, nerved.

Lip, yellow; petals, linear.

1. *C. Calceolus*.—Petals, not spirally twisted; deep purple.

2. *C. parviflorum*.—Lip, depressed in front; petals, twisted; flowers, perfumed.

3. *C. pubescens*.—Lip, convex in front; flowers, not scented.

Lip, yellow; petals, oblong.

4. *C. irapeanum*.—Whole flower, yellow; flowers, 4 inches across.

Flowers, rose-coloured; petals, oblong.

5. *C. marcanthorum*.—Petals, shorter than the inflated lip.

6. *C. centricosum*.—Petals, longer than the lip; flowers, much deeper coloured.

Lip, rosy; sepals and petals, white.

7. *C. spectabile*.—Sepals and petals, not spotted; stem, 12 to 14 inches high; three to five-leaved.

8. *C. guttatum*.—Sepals and petals, spotted; stem, 4 to 6 inches high; two-leaved only.

Lip, white; sepals and petals, green and red.

9. *C. candidum*.—Lip, pure white; sepals and petals, green, streaked with reddish-brown.

Lip, white and rose; lateral sepals, free.

10. *C. arietinum*.—Lip, white, chequered with bright rose; the lower sepals, not coherent.

Lip, rose; leaves, two, radical.

11. *C. acule*.—Lip, large, rosy-purple, furrowed in front; flower-stem, not leafy.

12. *C. palmifolium*.—This is a tall-growing species, not at present in cultivation.—*C. cordigerum*, a native of Northern India. This Lindley considers to be a white-flowered form of our own *C. Calceolus*, a widely distributed species, being found in Europe, Daburia, and, according to Thunberg, in Japan.—*C. passerianum* is described and figured in Hooker's "Flora of North America," t. 206, and is one of Richardson's species, being synonymous with his *C. parviflorum*, described in "Franklin," appendix i., 340.—*C. montanum* is another North American species, described by Lindley in his "Genera and Species of Orchidaceous Plants." It has a white inflated lip, similar to *C. spectabile*, and long narrow sepals nearly 3 inches long. All the above are little-known terrestrial species, probably not at present in cultivation.

II.—*Cypripedium*.

TENDER SPECIES.—Leaves, leathery, radical, distichous, persistent; flower scape, leafless, one or many flowered.

Foliage variegated.

13. *C. canstum*.—Lip, bronze-coloured, with deep green veins.

14. *C. concolor*.—Scape, one to two flowered; flowers, pale yellow.

15. *C. niveum*.—Flowers, white, with purple dots.

16. *C. javanicum*.—Lip, olive green, not veined.

17. *C. barbatum*.—Lip, deep purple; petals, with shining hairy warts along their upper margins.

18. *C. argus*.—Flowers, on long scapes, like *C. Hookeri*; petals, 2½ inches long, profusely covered with eye-like spots.

19. *C. porporatum*.—Dorsal sepal with revolute margins.

20. *C. Hookeri*.—Flowers, on scapes 16 inches high; upper sepal, not striped; variegation very distinct.

21. *C. superbiens*.—Petals, 3 or 4 inches long, white striped with green, and spotted with dark brown.

22. *C. Dugayum*.—Petals, white veined with purple, not spotted.

Green Leaves 1. Flowers, solitary.

23. *C. insipide*.—Upper sepal, green and white, spotted with brown or purple.

24. *C. ciliatum*.—Whole flower of a warm brown colour, shining, as if varnished.

25. *C. hirsutissimum*.—Petals, green at the base, dotted profusely with brown-purple, and slightly twisted at the apex.

26. *C. Fairbankum*.—Petals, curved downwards like an S; upper sepal, heavily streaked with purple.

Green leaved. Several flowers on a scape.

27. *C. Lowii*.—Scape, 2 to 3 feet long; three to five-flowered;

petals, purple and yellow, 3 to 4 inches long, spotted with brown at the base.

28. *C. Schlimmii*.—Flowers, small, white, with a rosy lip; petals, sometimes spotted with deep rose.

29. *C. caularis*.—Petals, linear, twisted, 15 to 30 inches long.

30. *C. Stonch*.—Petals, ligulate twisted; scape, sepals, and ovary, smooth.

31. *C. longipetalis*.—Scape, sepals, and ovary, hairy.

32. *C. coccinea*.—Leaves, grass-like; flowers, greenish; petals, 3 to 4 inches long, twisted like a corkscrew.

33. *C. plantaginifolia*.—Petals, acute, set with two or three hairy glands.

34. *C. Parashii*.—Petals, blunt at their apices, also with hairy glands.

35. *C. l. sp. folia*.—Flowers, green and purple, rarely more than one open at once on the same spike, with bracts 3 inches long.

36. *C. R. cili.*—Similar to the last; petals, purple; leaves, twice as broad.

There are several hybrid forms belonging to this section of the group, and I have thought it would be best to add these by themselves, as follows, with their parents' names in parenthesis. They are, in most cases, intermediate:—

C. Sedent (*C. longifolium* × *C. Schlimmii*).—Flowers, deep rose, 3 inches across; lip, crimson, white inside, spotted with rose.

C. Hæris-Simon (*C. barbatum* × *C. villosum*).—Flowers, shiny, as if varnished; foliage, variegated.

C. ve illarum (*C. Fairieanum* × *C. barbatum*).—Flowers, resembling the first named parent; foliage, variegated, like *C. barbatum*.

C. Damin (*C. candatum* × *C. Pearcei*).—A large flowered species, with the long petals of the first named parent.

C. Ashburton (*C. insigne* × *C. barbatum*).—Foliage, slightly variegated; flowers, resembling those of *C. insigne* without the spots. The produce of this cross varies very much, the foliage of some of the seedlings being nearly green, while others are almost as strongly marked as in *C. barbatum*.

I.—Cypripedium.

C. Calceolus (Common hardy Lady's-slipper).—This is one of the rarest, and, also, one of the most beautiful, of our native Orchids. It grows about a foot in height, and bears one or two showy flowers at the apex of the strongest leafy stems. Although a British species, the plants now in cultivation are mostly imported from the Swiss Alps. The sepals are of a deep purple tint, the petals being narrow, tapering with wavy margins. These are also of a purple colour tipped with yellow at their apices. The lip is rounded or swollen, and, being of a clear golden-yellow colour, contrasts well with the dark sepals and petals. It is found in woods in Russia, Asia, and Eastern Europe and the Arctic Circle, but is more sparingly distributed over Western Europe; in Britain it is almost, if not quite, extinct. One of the best known habitats of this plant was Castle Eden, Dean, Durham, and it has also been found in Yorkshire. According to Tenreiro, it is also a native of Japan.—Rich. Fl. Germ. 33, t. 496; English Bot. I., t. 1.; Paxt. Mag. 3, t. 247.

C. parviflorum (Small-flowered Lady's-slipper).—This has been more than once referred to the last-named species, from which, however, it is readily distinguished when both are seen side by side. The plant is similar in size and habit, but the lip is larger and distinctly flattened or even depressed in front, and the flowers are also delicately perfumed. The sepals are of a rich chocolate-brown colour, while the slender, wavy, or twisted petals are green at the base and streaked and spotted with dark brown. The lip is of a clear yellow colour, with a row of crimson or reddish dots around the mouth. The leaves are of a fresh apple-green; and the plant, although rare in even the best collections, is well worth introduction and careful culture. It is a native of Canada and, probably, of North America.—Bot. Mag. 23, t. 911; Linn. Trans. I. 2; Bot. Mag. 57, t. 3,024.

C. pubescens (Hairy Lady's-slipper).—This is a free-growing species, both stem and foliage being covered with whitish hairs. It is very distinct from both the last-named kinds, and grows well treated as a pot plant in a shady cold frame. The sepals are of a creamy-yellow colour, striped with bright red; petals narrow, very much twisted, also yellow streaked with red, while the lip is of a clear golden tint. In shape the flower reminds one of *C. Calceolus*, but it is readily distinguished from that species by the yellow sepals and twisted petals, and also by the flower being scentless. It is a native of North America, and common in good collections. It is also called *C. Calceolus* by Walt. and *C. flavescens* Red.—Lodd. Cab., t. 895; Hook. Bor. Amer., t. 206; Sweet Fl. Gard., 71.

C. inapeanum (Pelican-flowered Cypripede).—This is a very fine large-flowered species, recently re-introduced to our gardens by

Messrs. Backhouse, of York, with whom it has flowered. In shape, the flowers resemble those of *C. spectabile*. They are fully 1 or 2 inches across the fully-expanded segments, and are borne one and two together on the leafy stems. The colour is a bright golden-yellow throughout, and the lip is blotched within with bright reddish-crimson, and in shape reminds one of some of the large, flowered *Calceolarias*. It is a tender species, and does well potted in peat-loom, on a well-drained bottom. It requires plenty of water at the root when growing, and an airy atmosphere suits it better than a close one. It is a native of the Savannas, or great natural meadows of Upper Mexico, where it is found at an elevation of from 2,000 to 5,000 feet.—Bot. Reg. 32, t. 58; Flore des Serres, 3, t. 186.

C. maculata (Large-flowered Lady's-slipper).—This rare plant has often been introduced, although we do not now know whether or not it is in cultivation. It grows from 6 to 12 inches in height, and bears one or two rosy-purple flowers at the apices of the stems. The petals are striped, and the lip, which is inflated, is distinctly netted with dark veins. It is a native of Siberia, and is well worth general culture.—Bot. Reg. 18, 1,534; Bot. Mag. 56, t. 2,938.

C. ventricosa (Inflated Lady's-slipper).—This is another rosy-purple-flowered species, much resembling the last in general appearance, but easily distinguished from it by the petals being shorter than the lip, a very unusual occurrence in this genus. The lip itself is shaped like that of *C. macranthum*, but it is of a much deeper colour. It is a native of Siberia.—Sweet Fl. Gard., II. t. 1; Rehb. fl. Germ., 13, t. 497.

C. spectabile (Showy Lady's-slipper).—This is one of the most beautiful of the hardy species, and one which succeeds perfectly well planted out in a cool peaty compost, sheltered from the mid-day sun. It also makes a splendid pot-plant plunged in a cool and partially shaded frame. The stems rise from a foot to 18 inches in height, and bear from one to three large flowers at their apices; both leaves and stem are covered with short white silky hairs. The flowers, which measure about 3 inches across, are of pearly whiteness, the rounded lip being suffused with bright rose around its mouth. It is a native of the United States and North America, and should be grown in every collection of moisture-loving hardy plants. Also known as *C. album*, Ait.; *C. Calceolus*, Linn.; *C. canadense*, Michx.; *C. hirsutum*, Mill.; and *C. Reginae*, Walt.—Linn. Trans. I. 3; Bot. Reg., 20, 1,666; Sweet Fl. Gard., 240; Wooster's Alp. Pl., t. 1.

C. guttatum (Spotted Lady's-slipper).—This charming little plant resembles *C. acule* in habit, but has snowy flowers blotched with purple. It has been repeatedly introduced both to this country and the Continent, but received little attention until quite recently, when the plant has again been introduced, and, I believe, has flowered in Messrs. Backhouse's collection at York. The whole plant is only a few inches high, its short stems being two-leaved. It is a native of Siberia, North America, and Northern Russia, where it grows in swamps and spongy bogs.—Flore des Serres, 6, 573.

C. erubescens (Milk-white Lady's-slipper).—A pretty little species, similar in habit to *C. spectabile*, growing about a foot high, and bearing a solitary flower at the apices of its leafy stems. Its sepals and petals are white or greenish-white, more or less streaked and shaded with pale brown. The lip, which is inflated, is pure white. It is not unfrequently imported, and is well-deserving of culture. A native of boggy marshes, and extending into Canada to the northward, and to the Platte and Rocky Mountains to the west.—Bot. Mag. t. 5,855.

C. arietinum (Ram's-head Lady's-slipper).—This curious and interesting little plant is seldom seen in cultivation, although it has frequently been introduced to our gardens. Botanically, it is remarkable as being the only species with free lateral sepals, and this character serves to distinguish it from all the other species at present introduced. The lip tapers from the mouth to a blunt point; the colour being white, curiously chequered with bright rose, like some of the *Fritillarias*. The upper sepal is ovate, the lower sepals and petals being nearly linear, of a dull green colour, streaked with reddish-brown. The flowers, which are solitary, scarcely measure an inch across, and are not showy, although the plant is worth culture where variety and botanical interest are appreciated. It is a native of Canada.—Bot. Mag. 38, t. 1,560; Sweet's Flower Garden, t. 213.

C. acule (Stemless Lady's-slipper).—This is one of the commonest of hardy Lady's-slippers, and is frequently met with in good collections of hardy plants. Treated as a pot-plant in a cool frame, it does remarkably well, and blooms freely every spring along with *C. Calceolus*, *C. spectabile*, and *C. pubescens*. It grows well in an open compost of spongy peat, and, like its congeners, must have a copious supply of water at the root. The whole plant is 6 or 7 inches high, having two broad green leaves at the base, and a solitary nodding flower borne on a slender scape. The lip, the most con-

spicuous part of the flower, is rosy-purple, netted with darker veins, and curiously folded inwards in front—a characteristic peculiar to this species, which is sometimes known in books and gardens as *C. humile*. It is a native of North America, and is perfectly hardy. —Bot. Mag. 6, 192; Lam. Encycl. 729. F. W. B.

MIMULUSES INDOORS AND IN THE OPEN AIR.

THESE, though handsome, free-flowering, and easily-grown plants, are seldom met with now-a-days—except, perhaps, in an odd corner of some old-fashioned garden. Though, however, the taste for novelty has unhappily driven them into the background, they are, nevertheless, well worth attention. With the common Musk we are all well acquainted; and, as a window-plant, *Mimulus cardinalis* makes a good companion to it; for, though taller, it is equally fragrant, and its bright scarlet flowers are more showy than the small yellow blooms of the Musk. Both these *Mimuli* are quite hardy, and well adapted for borders. Many of the large-flowering varieties of *Mimulus* make beautiful pot-plants for the summer decoration of the greenhouse and conservatory, where they keep up a succession of bloom from the middle of June until August. A mixture of clay, loam, and a good quantity of silver or river sand suits them admirably. They should always be kept in a cool place, and liberally supplied with water. When done flowering, they should be placed in some sheltered corner outside, or in a cold frame, where they will remain all winter, and should be allowed to start into growth undisturbed until the young shoots are an inch long; they should then be taken out of their pots and divided if increase is wanted, or the whole plant may be re-potted in any desirable sized pot and replaced in their old quarters, to remain until ready for the purposes for which they may be required. Plenty of water while growing is, with *Mimuli*, more a necessity than any particular selection in the way of site or other requirements; indeed, they belong to a class of plants that readily accommodate themselves to circumstances. When growing them extensively some years ago I found the following varieties best suited for pot culture, viz., *M. aurantiacus splendens*, a kind with a golden-yellow ground blotched with crimson, and beautifully spotted in the throat; *M. albus elegantissimus*, a very finely spotted variety, with white ground, the lobes and margins being marked with crimson; *M. cupreus*, orange and crimson; *M. cupreus speciosus*, a kind with larger blooms than the *cupreus*, and more richly spotted with deep yellow and bronze-crimson; *M. coccineus*, fine scarlet; *M. guttatus* and *M. luteus*, both bright yellow; *M. exquisitus*, a sort with a beautiful orange ground brilliantly edged with crimson and elegantly spotted; and *M. meteor*, orange, with large violet and bronze-shaded blotches. The blooms of many of these have a peculiar musky scent, and are as exquisitely marked as those of any herbaceous *Calceolaria*. They look well when dotted here and there amongst other flowering plants, or placed together in groups; but those who have only seen them, even at their very best thus artificially arranged, cannot form any conception of the grand effect which they produce when grown in great natural masses. There are large patches of the beautiful yellow and crimson *M. maculosus*, growing wild in many of the quiet marshy nooks of the river Caddon, close by here, a mountain rivulet, the banks of which are richly clad with floral gems, such as wild Orchids and Irises. The Irises, like the *Mimuli*, grow in large clumps by the sides of the stream and in the quiet side pools of water; though their fine heads of bloom rise to a height of 3 and 4 feet above the surface, and have a fine appearance, still the *Mimuli* are the most attractive. I never saw the latter bloom in such profusion, nor so richly deep in colour as here. *M. maculosus* is not indigenous to this quarter, but has been cast out of some garden and deposited by the river in the places in which it now grows. With this variety alone, not to speak of other kinds, or of the greatly improved sorts which have lately been introduced, what an amount of embellishment might, with very little trouble, be given to the sides of lakes, ponds, and streams, and other places, in which little vegetation of an ornamental character will grow. In such situations *Mimuli* would delight. They thrive well with their roots entirely and constantly

covered with water, the foliage and flowers being allowed to float on the surface, and are exceedingly effective, either by themselves or mixed with other aquatics. J. MUR.

Cloverfords.

Hypoxis Rooperi.—This rare and beautiful plant is just now flowering in a cool house at Kew. In habit it is not unlike *Vellozia* (*Talbotia*) elegans, the deep green tapering leaves being arranged in three rows, or rarely distichous, their margins being set with white hairs; the flowers are stellate, each as large as a shilling, and are borne at the apex of a flattened scape, about a foot high; their colour is a deep bright golden-yellow, similar to that on the lip of *Oncidium bifolium*. There are several species in this genus well worth general culture. They are mostly natives of the Cape of Good Hope, and grow well either in a greenhouse or cool frame. *H. longifolia*, a native of Algoa Bay, has narrower leaves, 16 or 18 inches in length, and flowers over an inch across, of a rich yellow colour. It is figured in Bot. Mag. t. 6,035.—B.

Orchids in Flower at Kew.—A plant of *Oncidium Lanceanum* now bears a fine spike of richly-tinted flowers, the sepals and petals of which are rounded and slightly wavy along their margins, and of a dull greenish-yellow spotted with brown; the lip is richly coloured with a shaded band of purple, the apex being nearly white. This, though an old-fashioned species, is one of the finest in the genus, and the spike on the Kew plant is one of the best we have seen. Among the *Phalænopsids*, *P. grandiflora* and *P. rosea* (*equestris*), and *P. Ludemanniana* are in bloom. *Dendrobies* are represented by *D. Pierardii*, one of the most graceful of all the species when well grown, and a plant of the showy and distinct "Mayflower" of Ceylon, *D. McCarthiae*. *Trichopilia albidia*, also now in flower, is deliciously scented, the perfume being like that of the flowers of *Narcissus poeticus*; its crisped or undulated sepals and petals are very narrow, from 2 to 3 inches in length, and of an apple-green tint; the lip is pure white, the margins being slightly revolute. This plant bears from three to five flowers on a lax erect or drooping spike, and is grown in some gardens under the name of *T. fragrans*. The latter is, however, a distinct plant, all the divisions of the flower being of crystalline whiteness. A small plant of *Dendrochilum filiforme* bears two or three slender pendent spikes of delicate green flowers, which are arranged in two rows along the hair-like scape, and closely resemble golden filagree work in the delicacy with which the segments overlap each other. One of the most curious of the Orchids now in bloom here is *Acranthus arachnites*, a native of Madagascar. It resembles a *Saccolabium* in habit, having deep green distichous leaves, the flowers being solitary on long slender-nodding or pedent scapes. The sepals and petals are curiously curved, the lateral sepals being gibbous and concave, like those of *Sarcopodium*. The whole flower is of a pale greenish-yellow colour; and, although not showy, extremely interesting on account of its peculiar structure.—F. W. B.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Lapageria and Shade.—I know not why this does not do well with me, unless it is that my greenhouse is in too sunny a place. Does the plant like shade?—H. E. [Partial shade is considered one of the conditions of successful *Lapageria* culture.—Ed.]

Unusually Fine Japanese Primroses.—My plants of this Primrose have flowered splendidly with me this season. I measured the tallest of them, and found it to be 31 inches, and it bore seven whorls of magnificent flowers. None of my plants, of which I had 300, were under 18 inches in height, and among them I had a variety of colours.—ANNIE OWEN. [Were they in the open air?—Ed.]

Vitis tricuspidata.—A plant of this elegant cool greenhouse, or rather hardy climber, should be grown in every cool corridor or conservatory, where a vigorous growing plant is desirable. Grown under these conditions and planted out in a moderately rich border, it develops very fine foliage of a bright bronzy-green colour, and is one of the very best of foliage plants for such purposes.—B.

Ismene calathina.—This beautiful *Amaryllidaceous* plant is nearly related to *Guzmania* and *Pancratiums*, and, like them, bears its flowers in clusters at the top of a more or less flattened scape. Its segments and corona are of pearly whiteness, and the whole flower is most deliciously perfumed. The corona is irregularly six-cleft, the segments being fimbriate or fringed, and another peculiar point in the structure of the flower is that of the filaments being turned inwards at right angles, something similar to the style in *Gloriosa*. This *Ismene* grows freely in any light sandy compost; it flowers in May and June, and is much valued on account of its sweet-scented flowers.—J. M.

A Yellow-flowered Pelargonium.—It may interest your correspondent, M. Jean Sisley, and others, to know that *P. oblongatum*, a large-flowered species from the Cape, is now blooming freely in the Royal Gardens at Kew. It has a thick swollen root-stock, from 2 to 3 inches high, and is clothed, before flowering, with a few short stalked oblong or slightly heart-shaped, coarsely jagged leaves. Those fall off before the compound flower-spikes appear. It is a variable plant, some of the flowers being of a creamy white, while others are deep lemon-yellow, with purple streaks on the upper segments. It is worthy of attention as a decorative plant, inasmuch as it is a profuse flowerer. A good figure of it will be found in the Bot. Mag., t. 5,996.—B.

THE FLOWER GARDEN.

MARSH MARIGOLDS (*CALTHA*) AND *FICARIA*.

ALL those who care for hardy spring flowers cannot afford to dispense with the aid of these. The Marsh Marigold (*Caltha palustris*) that in early spring "shines like fire in swamps and hollows grey," is one of the finest hardy plants we possess, though it is so frequently met with in wet meadows and by the stream-side that there is little need to give it a place in the garden, except on the margin of water, where it is always welcome. Its double variety is, however, a garden plant of much value, and well worth a place in a moist rich border, or, like the single form, by the water-side, or in the artificial bog. This double Marsh Marigold is frequently seen in the London flower-market in spring. There is also said to be a double variety of the smaller *Caltha radicans*, which differs from the common plant in being about half the size, and by having a creeping tendency. Everybody knows the common *Ficaria* of our woods, with its myriads of polished golden flowers in spring. The white and double forms are well worthy of garden culture. Still finer, however, inasmuch as it is twice as large, is the, as yet, uncommon *Ficaria* or *Caltha grandiflora* (*Calthaefolia*). This fine species is a native of southern

England, though rarely—*Aquilegifolium*—hung its pretty lilac flowers everywhere, and I noticed that they were of a deeper lilac than those in cultivation. The sulphur *Anemone* (*A. sulphurea*) was perfectly lovely, far surpassing the *Adonis vernalis* we love so much as a spring flower in our borders. The prettiest of the *Columbines* is *atrata*, so common in this part of the Engadine. Though apparently so distinct from *vulgaris*, Grenier says of it, in his "Flora of the Jura," "I have seen this fine variety return to the normal conditions after two years of cultivation." *Aquilegia alpina*, with its solitary noble blue flower, grows plentifully on the skirts of wooded tracts up the mountain sides. Of the Poppies, *Papaver alpinum*, and the rarer *pyrenaicum*, occur in the Grisons on Piz Languard, and some of the Bernina Mountains. These are lovely in their Alpine homes. Among the Cruciferae, I would especially notice *Arabis cerulea* among the higher Alps. Its blue flowers are charming, and vie with the *Aubrietia*, which it somewhat resembles. Two Violets (one perfumed like our Sweet Violet) may be met with around Samaden—*Viola pinnata* and *V. mirabilis*. The pinnate leaves of the former sufficiently characterise it, they are so elegantly multipartite. *V. mirabilis* is a remarkable plant; the first that appear are sterile, large, with pale-lilac petals, highly fragrant, and the caulinary flowers are apetalous and

Ficaria calthaeifolia (one-third natural size).

France, and was introduced to our gardens some years ago by the writer, who gave some plants to Mr. Parker, of the Exotic Nursery, Tooting, who has since increased it abundantly, and cultivated it with success as a border flower. It is quite hardy, and thrives to perfection in ordinary open border soil. It is, according to a writer in the *Revue Horticole*, as valuable a plant as the Spring *Adonis* (*A. vernalis*). Mr. Parker's plants were, during the past spring, 15 inches high, and densely covered with large showy golden flowers. W. R.

FLOWERS IN THE ENGADINE.

It was about the middle of July, 1871, that I visited the Engadine, just when the Alpine flowers were in all their glory. I fixed my abode at Samaden, induced to do so by the variable nature of the soil that clothes the heights above the village, at one time consisting of glacier silt, at another giving indication of calcareous admixture. Out of upwards of 200 interesting plants that I collected, I shall choose the more local and remarkable. I shall begin with the *Ranunculaceae*. The Alpine *Clematis* (*Atragene alpina*) clothed the bushes with its climbing stems and deep violet flowers; it grows in all its beauty above Samader. A *Thalictrum* we sometimes see in cultivation in

fertile. Among the *Caryophyllaceae*, *Dianthus superbus* and *Silene nutans* deserve mention. The latter, indeed, is our Nottingham Catchfly, always indicative, I believe, of the chalk formation. *Hedysarum obscurum* is a conspicuous flower around Samaden, edging the sides of the mountain pathways. This and the lovely *Phacelia* are among the more attractive of the *Papilionaceae* flowers. You recognise many of our cultivated Honeysuckles in the wooded dells of the Engadine—among them *Lonicera cerulea*, *alpigena*, and *xylostium*, which last we surely can only claim as a stray in Great Britain. Samaden and Pontresina are exceedingly rich in *Compositae*. I need only mention, to prove my assertion, such plants as *Senecio abrotanifolius* and *carniolicus*, *Achillea moschata*, that yields the *Espirt Dica* of the Engadine, *Saussurea discolor*, *Hieracium albidum*, *Artemisia mutellina*, *Serratula Rlaponticum*, with many others. Among the *Lentibulariaceae* I found *Pinguicula alpina* and *P. leptoceras*, a gem of beauty, growing in Val Bevers. *P. alpina* differs in colour from others; the corolla is whitish, marked in the throat with two yellow spots. The *Primulas* come next, and they are well represented in the neighbourhood of Samaden. *Primula integrifolia*, *P. Moritziana*, *P. viscosa*, *P. latifolia*, *P. longiflora*, and *P. cœnensis* all occur in the Grisons, together with their little cousins, the *Androsaces*, of which *A. glacialis*

is, perhaps, the most lovely. Who can do justice, again, to the Gentians? Fully a dozen of these blue stars of earth are here, and you know not which most to admire as you walk over carpets of their flowers; the taller ones are on the slopes of the hills—*G. lutea*, *purpurea*, *punctata*—and many a time, when weary of mountain-climbing, have I cut off slices of the root, to revive and sustain me for further exertion. Among the Boraginaceæ I found *Cerinth alpinum*, that strange-coloured plant, both in leaf and corolla, where yellow and violet are made to blend and harmonise; *Eritrichium nanum*, with its little cushions of blue hiding its silky leaves—the very loveliest of our Forget-me-nots! How it grows on Piz Languard, braving the cold and the blustering winds. Among the Scrophulariaceæ—that anomalous group—the genus *Pedicularis* shows to advantage around Samaden. The Labiates offer you *Horminum pyrenaicum* that reminded me, somewhat, of *Salvia patens*, and *Dracocephalum Ruyschianum*, and the rarer *Austriacum*, that occurs, I believe, only in the Grisons and Valais. I must not forget to mention *Daphne striata*, a richly fragrant *Daphne*, that grows on the hilly slopes of Samaden and Val Bevers; the flowers are light pink, and have a long tube that is striate throughout its length; hence the name. As I climbed from Val Bevers up the slope to the summit of the plateau that overlooks Samaden, the rich perfume of this *Daphne* was almost overpowering. The shrub grows about a foot high, seldom more. Among the Liliaceæ I noticed, plentifully, *L. Martagon*, *L. bulbiferum*, and the pretty and delicate *Lloydia serotina*, growing and flowering in crevices where the granite silt afforded it root-hold; it looks almost like a miniature *Crocus*, its perianth being striped with rosy-red externally; the root-bulbs are very small. The *Pinus Cembra*, among Conifers, fruits in Val Bevers to perfection: the nuts are commonly used at dessert in the winter. In the summer, the trees were loaded with their bluish-coloured conspicuous cones.

PETER INCHBALD.

The Lodge, Hovingham, York, June, 1874.

BEAUTIFUL AND RARE IRISES.

By MAX LEICHTLIN.

It seems to me that *Iris susiana* is not so difficult to manage as other species in the same group. Every spring, my greenhouse is gay with potsful of *I. susiana*, each plant of which throws up from three to four flowers. Some time after flowering I keep them nearly dry, in order to give them a season of rest. I either plunge the pots or turn out the plants in some place where I can protect them from rain by means of a frame put over them, leaving the underground moisture alone to keep the plants alive until the end of August, when they have matured their rhizomes and can be started afresh. As regards soil, they are not very particular, but if they have any preference, it is for a loamy mixture, say, one part loam, and the other parts leaf-mould, sand, and decomposed cow-dung. I do not believe that they can be forced. Besides, the species named by Mr. Elwes (see p. 499) there are numbers of others, scarcely known, which well deserve cultivation. *Iris levigata* (Fischer) (syn., *Iris violacea*, Klatt) is a fine purple-flowered kind and perfectly hardy; *Iris juncifolia* (Niphion) is one of the most brilliant of the race, its flowers are of the brightest yellow imaginable, and comparatively large; but above all, *Iris setosa* (Pallas) and its varieties ought to be more generally grown in England. This species is better known to horticulturists under the name of *Kämpferi*, and the large and double flowered varieties, produced by the Japanese, and also, of late, in some European gardens, are truly magnificent; the flowers appear rather flat, presenting the outer segments in their entire dimension; the colours are very striking, they vary from white to lilac and violet, and from sky blue to indigo, brown, and blackish-maroon; they have but one defect, and that is, they often do not flower the first year after transplantation; the second year, however, they amply reward all who patiently wait for them. To grow them well and have plenty of flowers they should be planted in peat, and should be left undisturbed; they are perfectly hardy. *Iris nepalensis* (Wall.), which is considered, by competent authority, to be an Indian form of *Iris germanica*, is also a very beautiful kind,

which flowers very profusely in May, the inner segments of the flower (which is large) are of a bright sky blue, and admirably contrasts with the violet-blue, yellow-blotched, and bearded outer segments. In order that it may bloom profusely it wants a rich soil. *Iris tectorum* (Maximowicz) (syn. *Iris tomiolophia*, Hance), is not so showy as that just named, yet it is a very interesting kind, which, if planted in a sunny warm situation, will flower very abundantly, and show off its strongly crested blue and dark blue blotched flowers to great advantage. A rich soil, much sun, and some dampness, are the conditions under which it succeeds best. In Japan it grows on the top of straw-covered house-roofs, feeding on the decomposing straw, and exposed to sun and weather all the year round. Before long our collection of Irises will be enriched by the addition of some showy kinds from Asia Minor and Japan. I hope to flower some of the Japanese kinds in 1875, when they will be properly named and identified.

SAXIFRAGES.

By J. C. NIVEN, Botanic Gardens, Hull.

The Ligulate Group.

To anyone who is unacquainted with those structural organs upon which the relationship of plants, one to another, may be said to depend, it must be a matter of no little difficulty to recognise why plants so entirely distinct in foliage, flower, and habit of growth as this section presents, should be relegated to the over-grown genus *Saxifraga*, rather than formed into an independent little genus of its own. Haworth in his "*Megasea*," and Moench in his still more familiar "*Bergenia*," recognised the claims of this ligulate section to such a distinction, and our Saxifragean monographist, Engler, endorses the same after a negative fashion, by ignoring it altogether amongst the various sections into which he divides the old genus. Possibly he found, as others have done, both before and since, that the various species which constitute this section are in a lamentable state of confusion. In my endeavour to analyse it, I must only hope that I may escape making confusion worse confounded. Let me, then, first explain why we call this the "ligulate" section. I have seen it more than once Anglicised as the strap-leaved group of Saxifrages, but this is clearly a misnomer, as the outline or shape of the leaves is by no means such as would justify this descriptive title. If you remove one of the leaves with its foot-stalk complete, you will find at the base a stipulaceous appendage, at first somewhat membranous, but, as it acquires age, becoming quite leathery in character. These stipules, for such I take them to be, not only form a perfect sheath round the inner leaves or bud, but are also prolonged upward, very similar to the ligulate stipules of the Grasses—hence the true origin of the name. All the species are characterised by having large undivided leaves, of a leathery consistency, not fleshy, as the unfortunate name *crassifolia* would lead one to imagine. These are attached to a stout stem, that either runs along the surface of the ground, or sometimes grows erect, which stems often represent the growth of a series of years, branching, of course, as the process of flowering goes on. As was the case with our wandering friends (geographically a misnomer), reviewed in my last article, so these likewise have but a comparatively local distribution. They are, in fact, confined to the Himalayas and the far-east mountains of Siberia, and possess no European or new world representatives—at least none have as yet come under the ken of the botanist.

S. crassifolia of Linnaeus, claims first notice on account of its priority of introduction, dating back, as it does, to the time of Solander, about the year 1765. Its leaves are large, broad, and obovate in shape, with the base tapering down the sides of the petiole. The margins are slightly indented, and perfectly free from hairs, as also is the surface of the leaf; its flowers are produced in dense panicle cymes, rising from the terminal shoots in showy pendent masses; they are of a light rosy colour with the slightest lilac tint, and as they are produced in the months of March and April—in spite of the somewhat coarse appearance of the leaves—they form a very gay and useful accessory to the beauty of the spring garden. It is a native of the mountains of Siberia.

S. crassifolia var. *ovata*, as the name indicates, has oval leaves, the blades scarcely narrowing at all into the foot-stalks. It

throws its bloom well up, and is of a deep rose colour. For decorative purposes this variety will almost vie with *S. purpurascens*. It is, I think, similar to the variety known as *rubra*.

S. crassifolia var. *orbicularis*, sometimes dignified as a species, but I am disposed to consider it as nothing more than a small growing form, with the leaves rather broader than those of the previous variety, and a more branching habit. A free bloomer, producing an abundance of light rosy flowers, which are well elevated above the foliage.

S. cordifolia of Haworth, is by far the most frequently met with in cultivation, and, as regards nomenclature, is as often recognised by the former title as by its correct one, which it obtains from the heart-shaped character of the leaves. Compared with *crassifolia*, the leaves are much larger, nearly as broad as they are long, and distinctly heart-shaped at the base, also indented along the margin with a series of rounded little notches. The inflorescence is similar to the last, but produced in bolder masses; the individual flowers are larger, not so pendent, and of rose colour without the lilac tinge. This is the plant so frequently met with in old shrubberies, where it grows in enormous patches, holding its own well in the battle of life against all comers. It thrives under trees, enjoying the summer shade they afford, and gladdens the eye with the masses of pink flowers in early spring. It is a native of Siberia, and appears to have been introduced about the same time as the last species, but overlooked by Linnaeus, or perhaps considered only as a variety.

S. ligulata of Wallich is a Nepal plant with broadly obovate leaves, slightly ciliate at the margin and distinctly, but not densely, ciliated, the upper and under surfaces are glabrous. The flowers are produced in small cymose panicles, white, with a rosy tint towards the margin of the petals; the anthers, before expansion, are of a deep crimson colour, which adds much to the beauty of the flowers. Coming from Nepal and with the tendency to very early spring growth, it is liable to suffer from frosts; this form of injury occurring in three or four consecutive seasons so weakens the plant as ultimately to kill it; care, therefore, should be taken to give it a nice sheltered situation, where it may also have the benefit of a bit of shade.

S. ciliata of Royle.—Under this title, two plants, perfectly distinct, are figured respectively in the *Botanical Register* and the *Botanical Magazine*, the former represents a plant with leaves devoid of hairs, except at the margin, where they are densely arranged, and hence give rise to the appropriate specific title; the latter represents a plant whose entire leaf surface is covered with an array of erect somewhat bristly hairs, rendering the ciliated character quite inconspicuous. Which then is the correct one? Seeing that the most learned of doctors differ, I may well hesitate to give an opinion. One thing is certain, they are distinct plants; Royle, himself, in his description, says that the leaves are sometimes suffused with scattered hairs over the surface both above and below, but may it not be possible that he has mixed up two distinct species under one description. Taking, therefore, *S. ciliata* figured in the *Register* as the true one, and referring that of the *Botanical Magazine* to Lindley's *S. thysanodes*, I shall proceed with a brief description. The leaves are broadly obovate, slightly coriaceous at the base, perfectly glabrous on the surface, but margined with a dense array of somewhat bristly ciliae, accompanied by a conspicuous line of red colour; the flowers are whitish, not nearly as large as in the previous species, arranged in a lax branching panicle; the segments of the calyx are deeply divided and fringed with hairs. Our plant comes from the Mussoree range of hills, where it grows at an elevation somewhat lower than *S. ligulata*, hence the cultural remarks that I made will apply equally to this species as to that.

S. thysanodes of Lindley—in the *Botanical Register*—is undoubtedly the same plant as is figured in the *Botanical Magazine* as *ciliata*. It is of very dwarf habit; the leaves are broadly oval, supported on short thick fleshy petioles; they are covered with erect bristly hairs, both above and below; broadly crenate as to the margin, not cordate. The flowers are produced in small numbers on an almost simple inflorescence; the petals are of a creamy white colour tinted with crimson, short, expanded, and not nungulate; the calyx segments are entire, not fringed; the scape is a beautiful bright crimson, as also is the tube of the calyx. This plant was sent home by Royle from the Mussoree Hills, and is a much more tender species than *ciliata*; but, at the same time, more attractive, and well worthy the protection of a frame, or even a cool greenhouse.

S. purpurascens of Drs. Hooker and Thomson is, perhaps, the very finest of the whole section. It lays claim to Sikkim as its native habitat; there, at an altitude of some 12,000 to 14,000 feet it revels in atmospheric purity high above the Rhododendron zone of the Himalayas. Its leaves are smaller than any of the preceding, broadly ovate, perfectly glabrous and shining, with a smooth margin,

neatly edged with red, the same colour being also conspicuous in the mid-rib. The scape rises to a height of 10 or 12 inches, is considerably branched, and sparsely covered with dark glandular hairs; the flowers are produced in pendent masses, both calyx and corolla being alike as to colour, which consists of an unusual combination of red and purple. Though our plant is by no means a rapid grower, yet it possesses a good vigorous constitution, and is perfectly hardy. Unless increased by seeds it will be some time before it becomes plentiful in the country; at least, I know that I have always claimers in advance by the half-dozen for any duplicate plants I am likely to possess.

S. Stracheyii of Hooker is a strong-growing plant, somewhat closely related to *cordifolia*. The leaves are nearly as broad as long, slightly undulate; the margins obscurely indented, and lined with very short hairs; its flowers are produced in broad branching panicles, of a light pinkish colour with a shade of lilac therein. I have not yet had an opportunity of testing its hardiness; but, as it comes from a considerable elevation on the Himalayas, I should think it would prove as hardy as the preceding species.

ROSE HEDGES IN THE SOUTH OF FRANCE.

On our last excursion from Marseilles to Genoa, we were greatly struck, as any one seeing them for the first time would be, with the magnificence of the Roses all along the Mediterranean shores. The Rose hedges, and the espalier Roses, especially, offer an indescribably gorgeous sight. Under the genial influence of the warm sun of Provence, from the Corniche to the extremity of the Riviera di Ponente, that is as far as the Gulf of Genoa, and protected to the north by the mountains, which gradually slope down to the sea coast, Roses attain the size of Paeonies, and develop a depth and brilliancy of colour and a richness of fragrance of unusual intensity. But this is in part due to another cause, or rather two other causes, which lead to the same result, the main point being the choice of suitable subjects for stocks to graft upon. These stocks are, *Rosa Banksiae* and *Rosa indica* major. The Banksian Rose presents three varieties, namely, White Banksian, producing a profusion of small white flowers, scarcely so large as those of the double-flowered Cherry, and of a most delicious fragrance; Yellow Banksian, with still larger clusters of small mauve-yellow scentless flowers; Chinese Thorny Banksian, flowers less numerous and about three times as large as in the two preceding, and of the most grateful odour. These three forms attain an unsurpassable vigour in this region. In two years, one plant will cover an immense wall, the gable of a house, or climb to the top of a tall tree, from which its branches hang like flowery cascades, embalming the air around with a rich perfume during the months of April and May. Now, if these be taken for stocks upon which to bud some of the choicer Teas, Noisettes, and Bourbons, the growth of the latter will be prodigious. The stock should be two years old, having well ripened, though still smooth, wood. In this way such varieties as Gloire de Dijon, Maréchal Niel, Lamarque, Safrano, Chromatella, Aimée Vibert, le Pactole, and all the Teas, attain such dimensions as to be no longer recognisable. *Rosa indica* major is almost naturalised throughout the whole of this region. It possesses the additional claim to favour of flowering nearly all the winter, forming beautiful hedges of dark green shining foliage, from which thousands of clusters of lovely flowers rise, of a tender delicate transparent pink, or almost pure white, with a brighter tinge in the centre and at the tips of the petals. This Rose is an evergreen, and makes an excellent stock for grafting or budding. It is either planted in nursery beds, where it quickly throws up a stem suitable for standards in the same way as we employ the Dog Rose, or in hedges, and left to its naturally luxuriant growth to produce its own charming flowers in rich profusion, or rows of cuttings are put in where it is intended to leave them, and subsequently budded with some of the varieties of the diverse tribes we have named. We admire it most when treated in the manner last indicated. In the gardens of the Villa Lizerbe, Nice, the residence of M. Cazale, we saw three or four long hedges reared in this way; and, on the 6th of May, they presented a most gorgeous feast of flowers. To give only one instance, we plucked, at random, a flower of Gloire de Dijon, which measured 5½ inches in diameter, or 16½ inches in circumference. And it would not have been difficult to find even larger flowers. This is how the intelligent head gardener, M. Guichard, obtained such splendid results. The soil where the hedge was to be made having been moved to the depth of more than 3 feet, was planted towards the end of winter with cuttings of well-ripened wood of *Rosa indica* major, about 9 inches apart. They were left to grow as much as they would and not cut back at all. In August they were budded nearly close to the ground, and in the following year already they formed a hedge producing

flowers abundantly. Iron wire stretched upon slender Bamboo stakes is sufficient to support the branches. Pruning is only resorted to to keep them in shape, remove exhausted branches and shorten gross shoots. This Rose is also easily propagated by pegging down long branches or slightly covering them with earth, cutting them asunder at the joints when rooted, and thus obtaining as many plants as there are joints. By this very simple process M. Cazale has succeeded in raising his Rose hedges of incomparable beauty. From these hedges waggon loads of flowers might be cut every year. It is the varieties which flower in winter, amongst which Safrano is the very best, that are here propagated on a large scale. We particularly noted:—*Souvenir de la Malmaison*, *Chromatella*, *Gloire de Dijon*, *Général Jacqueminot*, *Maréchal Niel*, *Safrano*, and *Gloire des Rosomanes*. A large number of others grew and flowered equally as well as the foregoing. In conclusion, we recommend *R. indica* major as a stock wherever the winters are not very severe, and where earthing up or covering around the base is sufficient protection to secure the advantages of this vigorous growing species for this purpose.—*Illustration Horticole*.

Slugs v. Alpine Plants.—Being much annoyed by slugs, I at length determined to "fortify" my Alpine bed, and admit none but such as could "leap the ditch." This fortification I effected to my entire satisfaction by procuring a coil of zinc, which I cut into strips about 20 inches wide, and bent into U form, and buried as an edging round the bed, and kept it constantly nearly filled with water; and I found that neither slug nor snail ever crossed it, and it was very easy to banish all that happened to be enclosed. I connected this with a fish-pond, and it no doubt afforded the inhabitants a source of great pleasure, as they regularly made "excursions round the world," and seemed to benefit much by the liberty given them. In small pots standing in the water I planted several pretty plants, such as *Drosera*, *Pinguicula*, *Mosses*, &c., taking care that no bridges were formed; the effect was very pleasing. At several potteries they are now manufacturing pots and pans with double sides to hold water between them for the same purpose, and to keep up a constant supply of moisture.—T. MACGANN, in *Science Gossip*.

Destruction of Plants on Arthur's Seat.—Allow me to invite fellow naturalists to spare some of the rarer plants in Scotland by not absolutely clearing away everything in that way that comes before them. I will not enter on the subject of rare Alpine plants, for one must go to Clova or Ben Lawers to get at them; and now that other hills are being searched and new habitats are found, even if some of them get destroyed in some localities—as, for instance, on Ben Lomond—yet, it will be long before the plants themselves are wholly destroyed. As members of the Scottish Flora, something might also be said about the extinction of rare Ferns. But I put in a word simply for Arthur's Seat, where some plants, not uncommon in my early days, are now so rare, or confined to such neck-breaking parts, that one cannot find a specimen—say, of the Fork Fern (*Asplenium septentrionale*). Even the German Catchfly and lovely *Geranium sanguineum* are only here and there visible in inaccessible places.—NATURALIST.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Pond Weeds.—Will some of your readers kindly say what is the best way to keep a pond free from weeds, and a kind of green submerged Moss which in fine floats on the surface of the water? There are gold and other fish in the pond.—E. P. T., *Belfast*.

Linaria cymbalaria.—One of your correspondents recommends planting this on rock-work. Here it penetrates everything, even greenhouse walls, from which it is impossible to eradicate it. In short, it is quite a nuisance.—ANNIE OWEN, *North Wales*.

Rainer's Bellflower (Campanula Raineri).—This is now flowering freely in the York Nurseries—so freely, indeed, that I counted upwards of fifty blossoms on one tuft. The flowers are about the size of *C. tulipifolia*, borne on stalks from 1 to 2 inches in height, and a shade lighter in colour than those of *tulipifolia*. It thrives best planted in sunny positions in lawn freely intermingled with pieces of stone, and well watered in dry weather.—R. F.

Climbing Roses.—I am anxious to cover a piece of wall above the end of a lean-to Vinery with Roses. The wall is exposed to the full force of the east wind, and the site is 500 feet above the sea. I should prefer dark Roses, and hardy quick growing kinds.—FLETCHER DE LIS. [Try some of the *Bonsais*, such as *Gracilis* and *Amadis*, a purplish-crimson. *Inermis*, too, is a good bright red.—Ed.]

Autumnal Daffodils.—There are three or four species of *Narcissi* that bloom during the summer or autumn months about which I should like some definite information. *N. viridiflorus* is figured in the *Botanical Magazine*, t. 1, 1687, and bears inconspicuous green flowers with reflexed segments; *N. serotinus* and *N. elegans* are two other species mentioned by Baker in his "Review," about which cultivators seem to know but little. Can any of your readers tell me if these plants are anywhere in cultivation, or refer me to good coloured figures of them? It is not improbable that they may exist in some old-fashioned gardens, but these old things are apt to be overlooked in favour of more showy border flowers.—F. H., *Edinburgh*.

THE ARBORETUM.

TREES AND SHADE.

How enjoyable the shady nooks of our gardens have been during the broiling days of July, 1874, need not be dwelt upon. Any tree-shaded recess during the hot months of summer becomes the favourite garden resort during the mid-day glare; even the attractions of the flowers failing to make us linger long about the open parterres while the sun is high and the heat oppressive. Yet we do not seem to take so much pains as our forefathers did in the creation of green alcoves and cool arbours facing the north, of which one hears so much in the descriptions of old gardens; nor in the careful providing of the shady "wilderness," which was the ever necessary appendage to every English mansion of the olden time, though scarcely ever thought of in the formation of modern gardens, in which all is required to be so trim and smart that the delightful old bit of wild Nature has had to submit to banishment, and, along with it, its subdued light, its cool shades, and all the charms of its natural wildness, in which Bramble and Bryony were allowed to intertangle themselves with Ivy, as an undergrowth, and a Moss-grown pathway or two, could not even remain unmolested. In Elizabeth's time, Shakespeare often alludes to shady garden bowers and Yew arbours as favourite retreats in summer days; and delights to dwell upon such features in the gardens of ancient times. In old gardens, the cropped Yew or Holly hedges of great height, green walls of verdure, made gloriously shady walks, impervious to a single ray of light. Between two such hedges, constant shade prevailed; and a fountain at one end added to the aspect of refreshing coolness. Nothing would be more easy than to plan and plant summer groves, and groups of shade-giving trees, in every new garden, large or small, according to the space at command; for there is no necessity to have recourse again to the cropped Yew hedges or Yew arbours of our forefathers, or to any other kind of topiarian work. The central fact to be borne in mind about shade-trees is, that some kinds are frequently planted which are useless for this purpose. Shade-trees are of more importance in the heated streets of a city and in promenades; yet, as we write (13th July), the Mall in St. James's Park is thickly strewn with the fallen brown leaves of the Lime, and the trees above are yellow with the foliage about to fall. It is absurd to plant a tree to furnish shade which frequently begins to lose its leaves before the heats of summer have set in. Besides, our summers are short enough in all conscience, without planting the Lime to give us signs of autumn long before it really appears. Curiously enough, it is from foreign trees that we get the most perfect and refreshing shade. A good shade-tree should not only give a dense cool shade, but its green should be fresh and pleasant to the eye in the heat of summer. Mr. Meston thinks there is no better tree for shade than the Black Italian Poplar; and it possesses these essential qualifications even in London, where the Lime fails so much sooner than it does in the country. Some of the *Acer platanoides*, and the *Sycamore* and its varieties, are strongly recommended by Messrs. Osborn, of Fulham, who also mention the Horse Chestnut; but town planters would do well to bear in mind that this loses its leaves in cities prematurely, and somewhat after the fashion of the Lime. The Ashes have fine qualities as shade-trees, retaining their handsome leaves throughout the heats. The Planes are very fine, but somewhat open; they also begin to show the yellow leaf too soon, but never in a very objectionable way. The Tulip tree, when old and spreading, is a good shade-tree. *Populus alba* and *P. a. acerifolia* are also valuable. Perhaps the most charming green hues are afforded by Robinia and its varieties, which, though somewhat late in coming into full leaf, retain their exquisite verdure till late in the year.

Many trees may be named, which, in open situations, may be readily trained to form of themselves isolated shady retreats, even on a sunny lawn. The Weeping Ash, for instance, in a good situation, will very quickly form a perfect tent of verdure, providing ample room within its descending branches for garden seats, and even a rustic table. The Weeping Mountain Elm, again, forms a fine far-spreading canopy of very dense foliage, which, though not descending perpendicularly to the ground, and so forming an absolute tent, like the Weep-

SHADE-GIVING TREES.

ing Ash, is perhaps more impervious to the sun-rays, and casts a broad and deep shadow, in which a certain amount of coolness may be constantly enjoyed. Then there is the Weeping Willow, never yet utilised in this way, which, by careful management, might be made to form garden apartments of very picturesque character; for instance, let four young trees, high standards, be planted at the angles of a square about 9 feet in diameter, let a slight framework be raised, over which the lateral branches are to be trained; and in three or four years, an interlaced roof of summer greenery of considerable expanse will be formed, and, then the new branches may be allowed to descend all round, forming a screen, or rather gracefully descending curtain, surrounding the entire space intended to be so enclosed. This result being achieved, the trees may be allowed to pursue their natural growth, and all appearance of formality will rapidly disappear, leaving to the pleasantly enclosed and shaded space the aspect of being merely a graceful accident of Nature, especially after the removal of the original supports to the roof of interlaced verdure, which may be done as soon as the branches have permanently assumed their positions and acquired sufficient strength to support themselves without extraneous aid. Many other shade-producing devices of more or less pleasing and appropriate garden character might be formed.

The following list of shade trees has been furnished us by Messrs. Osborn:—

Acer	Juglans	Quercus	Tilia
platanoides	nigra	coccinea	americana laxi-
Pseudo-Platanus	cinnerea	palustris	flora
albo-variegata	regia	Robiniæ	pubescens leptophylla
tum	Liriodendron	Pseudo-Acacia	heterophylla
purpureum	Tulipiferum	crispata	Ulmus
Esculus	Platanus	macrophylla	campestri
Hippocastanum	acerifolia	Decaisneana	latifolia
fiore pleno	pyramidalis	Salix	suberosa
ohioensis	Populus	pentandra	pendula
rubicunda	alba	babylonica	montana
Ailanthus	acerifolia	Russelliana	pendula
glandulosa	caneescens	alba	major
Castanea	dalis	Sophora	pendula
vesca	tremula pendula	japonica	var. (Cann-
glabra	monilifera	Tilia	perdown
Fagus	angulata	europæa	Elm)
sylvatica	candicans	platyphylla	glabra
purpurea	pedunculata	intermedia	vegeta (the
pendula	sessiliflora	rubra	Huntingdon
Fraxinus	Cerris	aurea	or Chichester
excelsior	rubra	alba	Elm)
pendula		pendula	americana

H. N. H.

TREES STRUCK BY LIGHTNING.

At a late meeting of the Botanical Society of Edinburgh, Mr. McNab said that he had recently visited a large Sycamore, growing in the park at Woodburn, Dalkeith, which had been struck by lightning on the 25th June. The stem of the tree was 11 feet in circumference at 3 feet from the ground, and 70 feet in height, and of perfect symmetry. Considerable portions of the outer bark, varying from 2 to 3 feet in diameter, particularly on various parts of the upper branches, presented the appearance of having been scorched. Portions, from 1 to 6 inches in length, and averaging 2 inches in breadth, were more or less curled up, and seemed attached by the middle. On one spot alone had the bark been entirely removed, and in this instance the strip was about 2 feet long and 6 inches broad. Numerous lines were traced on the outer bark, as if carried off by the electric fluid as it was passing to the ground. It was difficult to say what permanent damage the tree had sustained, but towards the top of the south-west side it had a yellowish appearance. An Ash at Lugton, on the Dalkeith property, had been struck at the same time. This tree, which was about 8 feet in circumference and 50 in height, was struck one-third from the top. The bark had been entirely taken off, and the wood much splintered at the point where struck. At various places along the main stem the bark had been stripped off, and at the base the bark had been nearly all removed. Some Beech plants had at the same time been injured in the nursery grounds of Mr. Methven at Inverleith Park. On inspection he found a row of four-year old plants more or less damaged. The leaves had been burned, but otherwise the plants appeared in a healthy condition. Although in several cases he found that both the leaves and branches of Beech trees had been injured by lightning, there was not a case on record, as far as he was aware, of this tree having been torn to pieces like many others. Of late years many forest and ornamental trees had been damaged by lightning, and, although not instantly killed by the electric fluid, they were injured to such an extent as ultimately to cause death. Wall fruit trees were also

subject to the effects of lightning, and almost immediately a sudden browning of the leaves would be observed. In the case of stone fruit, besides this colouring of the leaves, the bark burst, causing a flow of gum from the injured portions. Sir Walter Elliot made a few remarks on trees which had been struck at Sidlaw last year, and, which up till now were not observed to be damaged. The President gave a short description of a large Oak which a few years ago was struck by lightning at Edmonstone House. This instance, he said, gave one an idea of the amazing power of lightning. The trunk on being struck was shattered to pieces, and, in proof of that, he had to state that large pieces, 9 and 10 feet long, were blown some distance off.

Singular Case of Branch-falling.—We have here a few of the best English Elms I have ever met with, one of which covers a space 79 yards in circumference, and has a height in proportion. The first branches are quite 30 feet from the ground; indeed, I do not remember ever seeing such a height and spread of branches combined. The trunk girths, at 4 feet from the ground, 13 feet 3 inches, and is, as the saying goes, "as sound as a bell," as are even the smallest branches. What storms this fine tree must have battled through, and yet not a limb has been lost. One, however, fell when least expected, not in a storm, but in one of the calmest nights of summer, during a heavy dew or fog. The branch which thus fell is 14 yards long, and measures 4 feet 10 inches in circumference. It is without split or other blemish, and I am at a loss to account for its snapping off otherwise than by the weight caused by the deposit of dew; or, possibly, the long drought has had something to do with the matter, the wood having become crisp through want of moisture. The occurrence took place on the night of July 9.—JOHN TAYLOR, *Hort. wicks Grange, Shrewsbury.*

New Weeping False Acacia (Robinia Pseudo-Acacia pendula).—To the above name we might, after the manner of many horticulturists, add the qualifying word *vera*, to distinguish the plant of which we are speaking from that which has long been sold for it, under the popular name of the Weeping Robinia, which has nothing weeping about it but the name. In fact, this last-named plant is a variety of *R. tortuosa*, of a somewhat vigorous growth, the longer branches of which bend down slightly in consequence of their length. The plant bearing the name, at the head of these remarks, is, on the contrary, of a distinctly weeping growth. The vigorous branches, which are often of great length, weep down towards the main trunk, after the manner of the *Slyphnolobium pendulum*. The foliage presents no special peculiarity, and resembles that of the typical species, or common Robinia. Where have we the plant we are noticing? We have admired it at St. Michel-Bougeval, in the garden of M. Couturier, the eminent nurseryman, of whom plants may be procured. We believe that it has even flowered, though we do not affirm the fact.—*Revue Horticole.*

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Olives out-of-doors at Clapham.—Mr. Hanbury exhibited at a recent meeting of the Linnean Society branches of Olive grown in the open air against a wall at Clapham, some bearing flowers, others nearly ripe fruit.

Raising Ground round Oak Trees.—Most certainly raising the ground over the roots of Oak trees (see p. 521, Vol. V.) will gradually kill them. Healthy Elms often bear covering over in that way with impunity; but my experience is that such covering is highly detrimental, and generally fatal, to Oaks. Build a rubble wall round the stem, 8 or 10 feet from it; this will help to extend the period of existence, but will not ultimately save the trees.—M.

True and False Retinosporas.—Retinosporas come mostly from Japan; but one or two of them, or what pass for such, are known to have originated from seed of the American *Arborvitæ*. M. Carrière, in the *Revue Horticole*, after a long study of them, comes to the conclusion that all the species of Retinospora fall into two series, and have been derived—one set from the American *Arborvitæ*; the other from the Chinese or Japanese *Arborvitæ* (*Biota orientalis*).

Cercis Siliquastrum in the Botanic Gardens at Leyden.—While visiting these gardens in the beginning of May, I was delighted with the beauty of this tree, of which there are in these gardens three grand specimens, one against a west wall, and two others against a south one. The circumference of the stem of one of these, at 6 feet from the ground, is about a foot, and it reaches to the top of the wall, which is from 15 to 18 feet in height; at the top, the branches extend horizontally to the length of 15 or 18 feet. During my visit, these trees were covered with flowers of a bright rosy-pink colour, produced in bunches from the old wood before the foliage makes its appearance. This gives the tree a singular but beautiful appearance.—A. M. C. JOSEPHUS COENIG, *Tuinen der Natuurhistorische Geseelschap, near Zoellie, Netherlands.*

Oak Trees in Chemical Manufacturing Districts.—The Oak is possessed of more vitality than most people are aware of. Living in the heart of the chemical manufacturing district of Lancashire, I have had an opportunity of observing the behaviour of this tree under difficulties. It is quite true that it is the first to show signs of decay, and that it yields to the influence of the noxious gases before any other British tree; but, after it has apparently withered, and to all outward appearance is dead, it continually, year after year, sends out again a few green shoots, thus showing that the roots are living, and to some extent vigorous. Other trees in this district which are susceptible to the gases, seldom send out any new shoots. Another thing worthy of notice is that tall trees suffer before shrubs or small trees.—R.

THE FRUIT GARDEN.

THREE CROPS OF MELONS FROM THE SAME PLANTS.

I HAVE hitherto been under the impression that one crop of Melons from each plant was all that could be got in anything like perfection in any one year; but this season we have gathered one crop, part of a second, and even a third crop is set and swelling. The plants from which so much fruit is obtained are grown in a close frame, heated by means of a 3-inch pipe run all round it for top-heat, and a similar amount of pipes for bottom-heat. Over the pipes for bottom-heat a vacant space is left, formed by placing boards 4 inches apart across the pipes, their ends being laid on bricks in such a manner as to raise them several inches above the pipes. Thin turves, with the green side down, are placed on the boards, which leaves a space 3 feet deep in front and $4\frac{1}{2}$ feet deep at the back. Into this space Oak leaves are then firmly trodden, leaving a foot clear between them and the glass. Below the centre of each light is placed a barrowful of good yellow loam mixed with a quantity of dry cow dung—materials which form a good compost in which to plant; and, as the roots extend, more of it is added from time to time until the bed is covered. When the plants have made six leaves they are pinched in, and as the laterals extend they are pegged down on the soil at regular distances apart; and, on reaching the extremities of the pit, their points are stopped, which terminates all further stopping until the first crop is ripe, unless any stray shoot happens to rise against the glass. When a fruit has fairly set and has commenced swelling, a brick or slate should be put below it to obviate discoloration by laying on the soil, and also to facilitate ripening. All laterals bearing fruit are stopped two buds beyond the fruit. When the first fruits have attained half their size another crop will be setting, which should be treated like the first, and when the first fruits are cut, a third crop will be setting. All barren and superfluous shoots should now be removed, as well as all decaying leaves. Watering is a matter of much importance. When the plants are put in, a good soaking should be given them, and no more will be required until the shoots have reached the sides of the frame, after which another good watering will be sufficient to set the first crop. After they have set and have begun to swell, they will require water regularly every week. To the plants under each light, I give once a week, four large potfuls of manure-water and two of clear water. The manure is given through the spout of the pot, and as little is spilt on the leaves as possible. The clear water is applied through a rose, and it washes any of the leaves that may have been touched with the manure-water. When the fruits begin to colour, watering is withheld until they are cut, after which, watering is carried on as usual, and between three and four in the afternoon is the best time for the operation. Syringing must be attended to night and morning, viz., in the afternoon when the temperature is about 100° , and first thing in the morning, unless the latter is so dull and cold as to render it inexpedient to lift the sashes.

JAMES MORRISON.

Fig Trees Casting their Fruit.—A friend of mine is in distress at the conduct of a fine Fig tree, which, after making a great show of fruit that promised to become very fine, suddenly commenced to drop its Figs, until, in a few week's time there were very few remaining on it. It is stated to have been well watered, and to all appearances healthy. Can you, in the absence of further knowledge of the circumstances, give a clue to the cause of the disaster, and its remedy.—R. CURRIE. [Upon submitting this case to an excellent Fig grower, he has kindly favoured us with the following reply:—The cold spring, and June frosts have killed the flowers, which are inside the receptacle, and which, after fertilisation, swell into the fruit. One of our own trees has suffered in the same manner. Even in more favoured climes, as in Judea, the same thing sometimes happens, and "the Fig tree casts its untimely fruit." That this is the correct explanation seems confirmed by the fact that the second crop of Figs, which appears when the summer is advanced, is not liable to drop, at least from trees that are healthy, and good bearing sorts. If your friend's tree is of the Brunswick variety, which is known by its large, handsome, and deeply divided leaves, it had

better be discarded, and a Brown Turkey, which is a first rate bearer put in its place, after renewing the soil.—G. S.]

Packing Grapes.—Nothing is better for this purpose than tin boxes, 18 inches or 2 feet long, 6 inches deep, and 12 inches wide; these sizes will be found to fit suitable-sized lampers. Packing materials should consist of fine paper-shavings or coarse unbleached cotton-wadding. It is not contact so much as rubbing which destroys the bloom of the berries; the bunches should therefore be packed very firmly, first wrapping each bunch in one or two sheets of soft tissue or fine drapery paper, and afterwards wedging them together in the box, so that when the lid is shut down they cannot move about, in whatever position the box or hamper may be laid or thrown. Grapes packed in this way rarely get damaged, nor is the bloom of the berries much affected.—*Gardener*.

Gooseberry Bushes for Garden Fences.—Why not? and also for hedges between arable fields on farms? There can be no question that a Thorn hedge forms a good fence, but it is no more than a fence; it needs good land and free exposure to light and air to grow it, and a great deal of labour to keep it in order, but it yields no profit. Perhaps nothing could be better for external fences or for boundary lines between meadows, where a strong fence is needed to prevent the passage of stock; but in such positions as those indicated above, an impenetrable barrier is of less moment. A certain amount of shelter, and a clear sharp line of division are all that is necessary, and these may readily be found in Gooseberry plants of various sorts. In fact, many varieties, such as the Iron-monger, Warrington, &c., with their long sharp spines, would make a fence almost as impenetrable as Quickset itself; and almost any sort of Gooseberry has spines enough to constitute it a good hedge plant. Of course a great deal depends upon the modes of planting and training. It would not, however, be difficult by a little manipulation to make a fence of Gooseberry bushes quite as impenetrable as most of those formed of White Thorn; but with even ordinary attention, they would form a fence sufficient for the positions thus indicated. Supposing them only to be used as dividing lines between gardens, what an immense gain to cottagers and small holders would result from it. Why, many persons might gather almost enough Gooseberries, green and ripe, to pay their rent, and would still have plenty left for their own consumption. Once make fences of them between fields, and there would hardly be any limit to the quantity of this wholesome fruit. For this purpose, the plants should be planted a foot apart, and pruned into a sharp-pointed pyramid, say 2 or 3 feet wide at the bottom, and to a point at the top, the height ranging from 3 to 5 feet, according to circumstances. Lines of this sort would not grow fruit of an ounce weight, but they would grow any quantity of useful fruit of medium size and of fine quality. It is to be hoped that many persons may decide to stub up their old Thorn hedges, and substitute Gooseberries.—*Florist*.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

How to Induce Side Branches in Apple Trees.—I have a young Apple tree, about 8 feet high, trained against a wall, the main stem of which is devoid of side branches for about 3 feet in the middle of the tree. What course should I take to induce the tree to push out side branches? Shall I have to cut back the leading branch?—C. [Make an open incision by means of two cuts above the dormant eyes, or graft or inarch shoots in the vacant places.]

How to cut Pine Apples.—When Pines are cut, as many of the short leaves that are found on the fruit stem, close to the bottom of the fruit as possible, should be cut with them. The natural garnishing which these small leaves afford the fruit when set on the dessert table is very effective. I have seen many forms of artificial garnishing tried, but none to surpass this. The want of these leaves on imported Pines very much impairs their appearance. When packing Pines to travel, these leaves should be carefully raised and tied up around the fruit with a bit of soft matting. In that way they help to protect the fruit.—J. MUIR.

The Grape Crop in California.—From the reports to local papers, the Grape crop of 1874 promises to be both heavy and of good quality. In Napa county the yield is estimated to reach probably 4,025 tons, or 537,000 gallons of wine. Sonoma county is estimated to yield from 10 to 25 per cent. more than last year. Other counties make similar reports. In Santa Clara, making raisins is a profitable business. Only about 75 per cent. of the Grapes in a Vineyard are suitable for raisins, and these shrink 33 per cent. in drying. A good Vineyard should therefore yield half as many pounds of raisins as there are Grapes harvested. California is for Vine growing the finest State in the Union, our hothouse Grapes thriving well there, whereas in the east they are a failure.

The Washington Pear. We have cultivated and fruited this Pear and highly commended it for more than thirty years, the first specimens ripening in the year 1836. We observe by the public journals that cultivators in many places are just awaking to an appreciation of its excellence. The tree is a handsome, although not rampant, grower, and is one of the earliest bearers, being excelled in this respect only by the Julienne and Bartlett. When well grown, the Pear is handsome in appearance, the crimson dots on the side next the sun adding much to its beauty. In flavour it is very sweet and excellent. Its drawbacks are—it is not large enough in size to obtain celebrity in market, and although very juicy and tender, it is rather breaking than buttery and melting in texture. It is one of the varieties that will flourish on almost any soil.—*Cultivator*.

THE GARDEN IN THE HOUSE.

ARTIFICIAL LIGHTING OF DINING-ROOMS.

[Miss HASSARD, so well known for her charming dinner-table and other floral decorations at our great flower shows, and who has so often contributed to THE GARDEN articles embodying her experiences in that way, has, we are glad to say,

Table with gaslight at each end.

acceded to our request that she would re-describe them in consecutive order. In the articles, of which this is the first, the whole question of table decorations will, therefore, be dealt with in detail.—Ed.]

The selection of stands for the decoration of the dinner-table must depend (as has been well shown by Mr. W. Thomson, in THE GARDEN, whose illustrations we reproduce)

Table with gaslight over centre.

on the manner in which the room is illuminated by means of artificial light. Generally speaking, there are but three ways of lighting rooms with gas or wax lights, viz., lights placed on the table, bracket or wall lights, and the chandelier or gasolier. The style of stand or stands selected for the table wholly depends upon which of these modes of lighting is adopted. For instance, if the room be lighted by two gas lights or chandeliers, one at each end of the table, a

March stand should be chosen; but if illuminated by a gasolier placed over the centre of the table, the selection of such a stand would be a mistake, for, the light being above the stand, though the flowers arranged in the top tazza would be well shown up, those in the lower one would be put into the shade; the top tazza would catch all the illuminating rays, and keep them off the lower one as effectively as if a screen had been placed over it. By such an arrangement as that shown in the accompanying illustration, each tier has its proper share of light. Where the gasolier is placed over the table, the best form to use is a high single slender trumpet, or some such shape, so that when the light happens to fall on it, it will not throw any shadow on the arrangement which may be placed round the base of the vase. When the light is placed over the centre, flat arrangements can be used with advantage, though for my own part, where possible, I give preference to something high in the centre. Undoubtedly the best stand for a room thus lighted is the trumpet, or some modification of it—such a stand, in short, as that represented by the accompanying illustration. When about to purchase new stands, these remarks should be borne in mind, and also when arranging pot plants on the dinner-table; for the mode of lighting affects them quite as much as stands. If the lighting is not taken into consideration, large Fern fronds and similar foliage would throw heavy shadows on the table-cloth, which would spoil the look of any arrangement in their vicinity.

Plants Placed Through Dinner-tables.

Many will doubtless be ready to exclaim, "Who would cut holes in one's dinner-table or table-cloth for such a purpose?" Well, allow me to explain how this can be effected without damaging either the table or cloth. With the exception of those who have seen suitable plants put through a table, no

Pot plant through table.

one can have an idea of the elegant effect which they produce when arranged in that way. Imagine the striking effect which young Tree Ferns or Palms have in such positions; their elevated fronds shading from the blaze and glare of light the smaller arrangements of flowers and fruits laid here and there on the snowy damask below them, a result which cannot be produced unless the plants are put through the table. This may be done in several ways. Dinner-tables are generally of two kinds—the one the telescope, into which may be put as many or as few spare leaves as may be desirable; the

Plant through table arranged with Ferns, &c.

other that with a large centre and spare ends, which may be added at pleasure. There are two ways of putting the plants through these tables. Now-a-days dinner-tables are never, I need hardly say, uncovered, therefore it is of no consequence of what material the top of the table is made, provided one leaf, reserved for a plant in the centre, or two if for a plant at either end, be made of common deal, either the same size as the mahogany one for which it is substituted, or only a foot or 18 inches wide, if the table is required to be made shorter.

This spare leaf should be cut in two, and a half-circular piece cut out of each piece, which, when replaced in the table, will leave a circular hole in the centre. Before this deal leaf is lifted into the space from which the mahogany one has been removed, a wooden box, or anything which will form a stand for the plant, should be put into proper position; the plant should then be placed on it and carefully raised to a proper height, keeping always the surface of the pots just below the level of the table. Each half of the spare leaf may then be fitted into its place, when the stem of the plant will occupy the centre of the circular hole cut for it. If there is a plant to be placed at each end of the table, the best way of supporting them is to place a long plank underneath. Should Ferns be used, the holes cut out of the spare leaves must be of the same size as the top of the pots, as, in the case of such plants, the pots must be flush with the table. The other plan of arranging plants in this way is to have a small piece of brass or iron that may be drawn across and fastened when the table is within an inch or an inch and a half of closing, which will prevent its either closing or opening. This form is suitable only for Palms, and similar plants. It is in this way the table with extra ends must be managed, and about which there is no difficulty; for I constantly practice it. Let us now turn to the covering of the table. The way the table-cloths (for it takes two to each table when so decorated) are arranged, is as follows:—Each cloth is opened and spread along each side of the table, so as to meet in the centre or lap over each other about an inch. They should be kept as flat round the base of the plants as possible, and the cloths should be pinned together so as to prevent them from being open. A clean flat-iron should next be obtained with which the folds should be neatly pressed, so as to obliterate any appearance of a join. If half the width of the cloth is not found enough to allow it to droop gracefully at each side all over more; but always keep the middle fold flatly pressed, a trouble which will be well repaid by the effect produced. My tables both at South Kensington and Birmingham had plants put through them. At the former I had a graceful pair of *Pteris tremula*, and at the latter a pair of *Chamaedoreas*. The accompanying illustration represents a plant of white *Bouvardia*, with Ferns and scarlet *Pelargoniums* arranged round the base. All plants put through tables should have some similar kind of arrangement round the base, otherwise they would look unfinished, and, indeed, anything but ornamental.

Incense.—At a meeting of the Society of Experimental Therapeutics, in France, an interesting paper was read by M. L. Marchand, on "The Origin and Uses of Incense." In regard to its origin, M. Marchand states that it has been known from the period of highest antiquity under the name *Oliban*, and has always been regarded as a precious substance. It was burnt in the temples of pagan divinities, and to the present day it is used in Catholic countries, under the name of incense, from the Latin word *incendere*, to burn. There is much discussion as to the source of incense. Some authors think that all the incense which arrives in Europe comes from Arabia; but it is certain that whilst much comes from Arabia, some also proceeds directly from the trees of Abyssinia. According to M. Schimper, the resin is produced by a tree named *Boswellia floribunda*; others, with Flückiger, suppose that it is the *Boswellia sacra*; whilst others again, with Birdwood, attribute it to the *Boswellia Carteri*. M. Marchand distinguishes two species of officinal incense: one in small leaves mixed with more or less *débris* of bark; the other in large fragments of finer quality. The former was called male, the latter female, incense, by the ancients. Female incense is the produce of the *Boswellia papyrifera*, a plant that is only found in Africa. Male incense, on the other hand, is obtained both from India and Africa, being the produce of the Indian species, *Boswellia thurifera* or *serrata*, and the African species, *Boswellia sacra*, B. *Carteri*, B. *Bhan-Djanna*, Mohr, and B. *Feriana-Vegae*.

The Dismal Squares of London.—*Punch*, after commenting on the renovation of Leicester Square, says:—

Who follows suit? *Punch* wants to know—
Lifts thy square (*once* King's Place), Soho,
From squalor sad to think on—
Regards the square still "golden" bright,
And sets the lamps of legal light
High in the fields of Lincoln?

THE KITCHEN GARDEN.

SEAKALE CULTURE IN THE MARKET GARDENS OF LONDON.

SEAKALE is one of the most important crops grown by the London market gardener. It is either an annual or biennial crop, easy to cultivate, accommodating in its habit, free from insect pests; and, altogether, it gives little trouble and is highly remunerative. Growers in the Fulham fields, the Chiswick and Barnes Thames level, the Deptford and Woolwich neighbourhoods, and, in fact, for many miles round the metropolis, pay much attention to its growth, and regard it as one of their principal crops. From the first week in November till the end of April it is abundantly supplied in our markets.

Propagation.

The common way of increasing Seakale is from cuttings of the thong-like white fleshy roots, which are cut away from the crowns when these are lifted for forcing. These thongs, when removed, are thrown into a heap in a shed, there to remain until all the plantations that are to be lifted for forcing are up and dressed. The best are then selected, cut up into pieces about 4 inches in length, and laid in a heap by themselves. The remainder are either burned, along with prunings of trees and bushes; committed to the dunghill, where there is a herd of pigs, and where they are not likely to be disturbed until they are so decomposed as to be exhausted of all future efforts at new life; or, most commonly of all, carted away to some useless corner, where they are built into a heap, there to remain and rot throughout the succeeding summer. Beds are in the meantime prepared for the cuttings, from 4 to 6 feet in width, any length, and raised, like a seed-bed, about 4 or 6 inches higher than the surrounding level, to keep the Seakale roots healthy and free from damp. The cuttings are then brought hither, and a layer of them, nearly 2 inches in thickness, placed on the surface, and over them another layer of soil about 2 or 3 inches in depth. This being generally done in January, all is left undisturbed till planting time, which is commonly in March. The beds are then uncovered to unearthen the roots, which will have started several eyes, and emitted a quantity of white feather-like rootlets. As now the top and bottom ends of the sets or cuttings can easily be discerned, men and women are set to work at them to rub off all eyes excepting the strongest top one, and to arrange them by placing all the head ends one way and the bottom ones the other way, and in this manner placing them in baskets for the convenience of the planters, who dibble them into the ground head end upwards. Instead of placing the made cuttings on the bed used for starting them, some growers lay thereon selected, but uncut, roots, and at uncovering time they cut back these roots to the best eye, then cut them at the required length below it, and rub off all other eyes, as in the previous case. By this plan good eyes are neatly and certainly secured; but the practice is more laborious than in the first case. Seakale, too, is raised from seed in some cases; but it is considered a tedious and almost needless way, considering how easily they are obtained from cuttings; and I think I can do no better than relate how Mr. Myatt, the famous market gardener at Deptford, propagates this vegetable from seed. In March he selects a piece of ground in some corner of his garden, digs it deeply or trenches it, but gives it no manure, if it had been liberally treated in that respect for the previous crop, and thereon he forms a series of 4 feet wide beds, with 1 foot alleys between them. On these beds he sows his seeds quite thickly. When the seedlings appear they are left unthinned and unmoved during the succeeding summer and winter, with no care being paid to them whatever beyond cleaning, which is attended to to prevent the weeds from seeding, thus preserving the soil from a succession of these pests. Early in the following spring, or when the plants are twelve months old from the time of sowing, they are lifted, cut into 4 inch lengths, to which are preserved the crowns, the remainder being thrown away. These pieces are then planted permanently at once, and will be equally strong with the plants from root cuttings. The objection to seedlings, however, is that they solely occupy

the ground under the seed beds for one entire year, without yielding any return that season, and also that during the second summer they are sometimes liable to produce multitudinous crowns; and, unless extra labour is expended in reducing them, they form but weakly subjects for next winter's forcing. By lifting them in January instead of March, cutting them back as before directed, and placing them in layers on beds, as already advised for root cuttings, all starting eyes, excepting the main single crown, could be rubbed away, and thus much labour saved. Why are not the seedlings thinned and planted out the first season of their existence? may be a question asked by many, and it is one that Mr. Myatt's experience soon settles. He has tried that mode of treatment, and, even with great care, found the majority of his plants "bolted" during the summer, and at lifting time the roots were too weak for any payable purpose; consequently they require another year's growing, and unremitting attention in reducing their many crowns; therefore he has discarded the practice, as being a troublesome and unprofitable one.

Planting and Summer Treatment of Young Plantations.

The Seakale cuttings being prepared and in readiness for planting, that operation is usually performed in March. No ground is prepared for them alone, but they are inserted with iron-shod dibbers at certain distances amongst the crop at the time occupying the ground. As a rule, the most approved method of cropping the Seakale ground at planting time is this:—The ground, after being well manured and doubly dug or trenched in winter, is levelled in February, and lines drawn along it $2\frac{1}{2}$ or 3 feet apart for Cauliflowers, which are then planted, keeping them at the same distance asunder in the rows, or more generally at that of the least distance. Between the lines of Cauliflower, other lines are drawn precisely in the middle—but this line is more commonly guessed at than measured—and in it are planted white or green Paris Cos Lettuces, only half the distance asunder in the rows as the Cauliflowers. In the rows occupied by the latter, too, Lettuce plants are inserted alternately with the Cauliflowers. Thus in the field there will be, when finished, three Lettuces for every single Cauliflower. The ground is now ready for receiving the Seakale, a set of which is planted with the dibber, alternately with Lettuces and Cauliflowers, in all the rows. The Lettuces are first ready for market, and are commonly removed before they can injure the Cauliflowers. By the end of May, most of the latter crop is also marketed, thus leaving the Seakale, which, by this time, will be coming up strongly, in sole possession of the soil. Mr. Broadbent, of Parson's Green, Fulham, an excellent gardener, plants his Seakale sets 15 by 18 inches apart amongst his spring Cabbages, which are all removed before they can materially injure the Seakale. Mr. Dancer, nurseryman and market gardener, Fulham, plants some of his sets in the alleys between his Asparagus ridges; but in this case they must all be lifted at the end of the first season. Mr. Geo. Steel plants some of his sets in rows between his Gooseberry bushes and Moss Roses; but they must always be removed for forcing at the end of the first season. Some nurserymen plant their sets at 18 inches apart each way, and never inter-crop the ground amongst them, but take great care of them; and, under such management, they get finer roots than can be produced in the market gardens. These nurserymen's roots being all lifted next winter, the best are sold for forcing, and the weakest cut back and sold as planting plants. It is a stupid practice, however, to buy plants for transplanting, for sets are decidedly better. The plants give trouble in reducing the number of their crowns and flower-stems in summer; whereas the sets, if properly made and treated, give hardly any, and in one year make almost as good crowns as the real plants will. In any case no further care is necessary throughout the summer and autumn than at first hoeing the surface soil weekly, whether it is dirty or not, cutting away all flower-spikes, as they only tend to weaken the crowns, and rubbing off all small shoots that may chance to spring around the main one; but this is an infrequent occurrence in the case of properly-prepared young plants. All vacancies in the plantation caused by blind sets, or others inadvertently hoed off or irreparably bruised in planting, should be made up with Lettuces. Towards the end of the

year, if the plantation is to be entirely lifted for forcing—say about the last week in October or the first fortnight of November—just as soon as the leaves have decayed, they are raked off into heaps with a wooden-toothed rake and carted to the manure-heaps. Sometimes they are left as a partial protection against frost.

Winter, Spring, and Summer Management of Old Plantations.

Although young Seakale are the most suitable and convenient for forcing, still there must be a portion, if not an entire plantation, left for producing "natural" Seakale, *i.e.* the Kale unforced. In private gardens this is commonly done by covering the crowns with pots made for the purpose, or a framework of wood covered with a mulching of leaves to exclude light; indeed, in the same way, but with increased covering of leaves or litter, the bulk of the Seakale is forced. The object of this old-fashioned and really troublesome plan is to save the forced plants for another year's use, thus incurring a watchful attendance during the succeeding summer in cutting out the flower-stems and reducing the shoots; otherwise, if left to grow as they can, they will produce multitudinous weak crowns, that will bear as many, if not more, weakly ones next year. If a young plantation be made every year, part of it to be lifted for forcing, and part left for spring use, to be grown on next summer, and lifted for forcing in winter, less time, ground, and trouble are required than by adopting the old principle of keeping the same plantations untouched year after year. In the end of autumn or beginning of winter, all roots to be forced may also be lifted, and lined in as closely as they can be put in some cool corner out of doors, to be taken into the Mushroom-house as required, and thus the piece of ground they occupied is empty and ready for manuring, trenching, and ridging, and in good condition for early cropping in spring. In market gardens all plantations are made as recorded under the preceding heading; and if the field is to be kept to yield "natural" Kale, every third row is lifted, and thus the rows are left in pairs, having a space of nearly, if not quite, 3 feet between them. The surface of the soil is then raked clean, and from this wide space the rows are earthed over to the depth of half a dozen inches, any time between November and February, but the sooner the better, so as not to interfere with the other work, and also to prevent the frost penetrating the ground amongst the crowns and thus rendering it cold and late. The Kale begins to push about the second week in March, and, according to the position of the field, and nature of the soil and weather, a supply may be gleaned therefrom till the end of April. As soon as the point of a shoot of Kale is discerned above the ridge, that head is fit for cutting, which is usually done twice or three times a week. In cutting, the soil is drawn away with a spade from every visible shoot, which is cut over just into the crown, and laid on the ridge top till all have been cut; or women with baskets come after the men and take them to the outside at once. The earth is not replaced again, except so much as is necessary to keep the ridges from breaking down, and thus leaving uncut crowns uncovered. When the day's cutting is over, the Kale is placed on its ends in broad shallow baskets, carried by men and women, or carted home, where it is washed, tied in punnets of a dozen heads, again packed into baskets, which are piled on waggons and sent to market. After all Kale is cut, the ridges are levelled down, and the space between the rows cropped with white Cos Lettuces, which heart at this season better than any other sort. Immediately the Seakale begins to grow numerous crowns are produced; but these are all reduced to two, or at most three, of the strongest, and in this respect, in removing their flower-spikes, and in keeping the soil about them loose and clean, they are well attended to afterwards. These old roots are used next winter for forcing, but I have known them, as in the case of Mr. Bagley, Turnham Green, to be kept for two or three years, but they gave continuous trouble throughout the summer, however, and the older they became the more annoying they were.

Forcing.

Never have I seen Seakale forced in the ground as it grows in any market garden, for such a practice would be far from

remunerative; indeed, all the Kale that could thus be forced would not pay for the trouble taken with it. In market gardens the roots are all lifted and dressed for forcing, cutting away the thongs to within an inch or two of the main root, as explained under the head of "propagation." If the Kale be required early, say in the first fortnight of November, the very best crowns and such as are best ripened, which will be seen by the leaves being withered the earliest, should be selected, as it is a difficult matter to get Seakale to start so early, notwithstanding its being the easiest of all vegetables to force. Having the crowns in readiness, a hot-bed is prepared for starting them in, which, in the case of the earliest batch, merely consists of a dung-bed covered with frames and sashes, and a few inches deep of soil levelled within the frames for planting the roots amongst, and that is done as thickly as they can be conveniently stowed together. It is endeavoured to keep up a heat of 65° or 70°, as they require a little extra excitement to influence them thus early. Litter or mats are kept on the surface over the glass, so as to keep all dark and blanch the Kale. Mr. Humphreys and Mr. Steel endeavour always to have a good cutting of Seakale in time for Lord Mayor's Day in London; but, as a rule, this is considered too early for regular forcing. When the time comes—about the first fortnight in November—the beds where Cucumbers were grown during the previous summer are cleared out, and re-filled with hot dung, over which about 8 inches deep of soil is placed and levelled, but no frames are used for the Seakale. A notch is then made crosswise in the beds, and therein the crowns are planted as thickly as possible, earthing them up to the top, which is left bare, and proceeding in this way till the whole bed is finished. The lines across the bed are about 5 inches apart, and about the same space of a margin is left empty on each side. Amongst the roots, and lengthwise in the beds, four rows of short stakes are inserted, so that they may be 18 inches above the soil. Some 6 or 7 inches deep of short litter is then strewn over the whole surface of the beds, which are then covered over with mats supported on the ends of the stakes.

When these stakes are not used hoops and mats are employed for the purpose. In about three or four weeks after the beds are made up cutting generally begins, when it is necessary to uncover the beds as the operation proceeds, drawing the short litter off the crowns to get at them, and replacing it as speedily as possible, as all the crowns are not fit to cut at the same time. For cutting the forced Seakale a small tool with a handle about 1½ feet long, bent at the neck, and with a blade about 2 inches wide by 3 inches long, like that of a spade or Dutch hoe, is used. This is a handy instrument, and well adapted for its purpose, as it may be so deftly employed for cutting over the Kale with a small piece of the root-stock adhering to it. The mode just described of forcing this vegetable is only that practised as regards the earliest beds; and, indeed, many growers do not adopt it at all, whereas all market gardeners that make Seakale forcing a part of their business form their beds, particularly the late ones, as follows:—A well-sheltered plot, near home and the manure-heap, is selected and lined off into spaces either 4 or 5 feet wide, with intervals 2 feet wide between them. These spaces are used as beds, over which the soil from the alleys or intervals is placed, after finely breaking it, until the alley is 20 inches deep. The Seakale crowns are then all lined into these beds as described in the case of earlier beds, and thus the beds are left uncovered until they are required for forcing; but, as a rule, two or more of them are always being forced, and others started to succeed them. As these beds have no bottom-heat, it is not necessary that they must be immediately covered, as in that case they, being incited at the bottom, would grow, no matter whether their crowns are cared for or not; but, in this instance, having no exciting agent, and being in a dormant state, they await the cultivator's convenience. In forcing them, the alleys between the beds are firmly filled with fermenting manure, and the beds being covered as formerly directed with short litter and mats supported on the upright stakes, all is finished. The Kale takes a longer time to push into growth by this means than when forced on a dung bed, and it does not come quite so regularly. This method, however, has the advantage of less trouble and risk, and great convenience in keeping up

a supply until it can be produced from the open-air beds, at which time all forcing should desist, and the forced roots should be forked out and removed to a heap by themselves, or to the piggery, where their vitality is sure to be destroyed—otherwise, if mixed amongst the dung, conveyed to a field at once, and dug into it, they would certainly grow again, and prove a future annoyance. The dung being forked out from between the alleys, the soil is levelled, and the piece of ground will then be ready for digging over for French Beans, Cauliflowers, Tomatoes, or for erecting Cucumber frames on. Mr. Gilbert, of Burghley, has a good method of heating Asparagus beds, which appears very feasible to me as regards Seakale beds, and I have recommended it to several market growers, who have promised to give it a trial. This plan is to get 2-inch drain-tiles, which he inserts at short intervals into the sides of the beds, so as to admit the heat from the fermenting material in the alleys to the interior, and thus increase the temperature. —*Field*.

Successional Cabbages from the Old Stumps.—Any authoritative work on gardening will tell you, with regard to Cabbage, to sow in autumn, spring, and midsummer, and to plant as often—a course of practice which most gardeners have discovered to be quite unnecessary. Cauliflowers and Brussels Sprouts cannot always be had just when wanted; but tender Cabbage—and what is nicer or more wholesome?—may be had with very little management. Supposing we plant Cabbage in autumn, late, or in spring, they will come in for use nice and tender towards the beginning of summer; but, as the household is generally not able to use them as fast as they grow, the heads are allowed to swell until they burst, or go to seed or rot, and eventually become quite useless for cooking purposes. This, I am quite aware, is what takes place in nine cases out of ten with the Cabbage crop in summer; and, consequently, it is imagined that another successional planting is required to continue the supply; but this is a mistake. In gardens from which large establishments have to be supplied, it is seldom that more than one, or at most two, plantations are made during the twelve months; and the reason is this—that, as the Cabbages are ready, they are generally wanted, and a certain number of heads are cut daily; but the experienced gardener does not cut the head off at the surface of the soil, but just at the neck, leaving a few of the bottom leaves. Consequently, before the quarter has been cut over the first-cut plants have made another break and become furnished each with a whole cluster of young succulent heads, which fold immediately, and are fit to cut before the first heads are quite finished. The plants will even break and fold a third time, and in this way a quarter of Cabbage may be made to afford a supply nearly all the year round. The vigour, free growth, and tenderness of the heads will be greatly promoted by frequent stirrings of the soil between the rows, and mulching with any loose material, such as short Grass or leaves, at command. Cut your Cabbages, therefore, if you have to give them away to your neighbours, before the heads get over ripe and useless, and you will have a continuance of young and tender heads such as most cooks prefer to heads which are large, white, and hard. To ensure a winter crop, in case of the sprouts being run upon too much, a planting may be made in August or the beginning of September of some dwarf kind, and also the Enfield Market variety.—J. S. W.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Potato Disease.—The soft white-looking Potato tubers found among early Potatoes after being cooked are those in which there is incipient disease, and such Potatoes are always the first to go wrong when a change of weather takes place. Thunderstorms, followed by cloudy drizzling rains and fogs, hasten on the lurking malady at a great rate; it shows itself all at once, to the astonishment of those who had no idea that disease was lying in wait, as it were, ready to be developed. This has been the case in previous years, and the same thing will happen this year within ten days or so. Then every one will say that their Potatoes were destroyed in a single day or night. This is, to some extent, the reason why nothing more is known of the cause and cure of this disease than there was nearly thirty years ago. The next fortnight, as I have predicted, will produce a great outcry about such sudden attacks, as if disease really ever did attack the Potatoes suddenly.—JAMES BARNES, *Edinburgh*.

Recent Discovery of Guano.—A short time ago, some extensive beds of guano were discovered in Peru, to the south of the Province of Tarapaca. An examination of the beds has recently been made by two surveyors, who were sent out by the Central Board of Engineers of Lima, Peru. Their report is of very great interest, as it shows that several large beds of guano, of excellent quality, exist in that locality. Those which have been surveyed, are estimated to contain nearly 5,000,000 tons; one of them alone contains 5,000,000 tons of fine quality. These fortunate discoveries not only remove all fear of a present failure in the supply of guano, but indicate that there are yet other undiscovered beds in existence, which will provide a practically inexhaustible supply.

GARDENING FOR THE WEEK, AND AMATEUR'S CALENDAR.

The Flower Garden and Pleasure Grounds.

MANY annual flowers, such as *Nemophilas*, *Clarkias*, and many other species, although exceedingly beautiful while in bloom, are yet of short duration, even during favourable seasons, and, of course, more so during such seasons as the present. They should (if the seed is not required) be cleared off as soon as their beauty is over, and be immediately replaced by some other species of plants from the reserve garden. Attend to the various sorts of plants in the flower beds, as regards training, pegging down, watering, &c.; and regulate the growth of standard and pyramidal specimens of *Fuchsias*, *Pelargoniums*, *Tropæolums*, *Clematides*, &c.; while drooping plants in baskets and vases, will also require to be occasionally regulated and trained, so as to be made to depend gracefully over the sides, and around the margins of the same. Plants suitable for this purpose, are the various sorts of Ivy-leaved *Pelargoniums*, *Clematides*, *Convolvulus*, *Maurandias*, *Lophospermums*, and many others. Hardy shrubs and trees have now nearly finished their annual growth, and their foliage has, in most instances, attained its full size, and has also acquired the hue or colour of maturity; so that the present is a very appropriate time to make notes having reference to any contemplated thinning out, or other alterations which may be deemed desirable, and which it may be intended to carry out at a later period of the season. In all cases, however, where it is intended to attempt the improvement of garden and park scenery, whether by the removal, or transplantation of existing specimens, or by the introduction of new varieties, it is necessary in either case to exercise considerable care in the matter, and to make as sure as possible of the adaptability of newly-introduced plants to the situations where they are required; taking into consideration the habit of growth and form which such trees are likely to assume when in a fully developed condition, whether they will be of drooping habit, round-headed, or of pyramidal form; even the colour, form, and size of foliage should have careful consideration. The character and quality of the soil should also have due weight in the forming of selections of trees and shrubs, as it not unfrequently happens that certain species will succeed admirably in soils where other members of the same family will almost invariably fail. As an illustration of this, it has often been observed that where *Picea* *Pinus* succeeds well, *Abies Douglasii*, on the contrary, fails, and *vice versa*. It happens not unfrequently among Coniferous trees that rival leaders are produced, and, whenever this is the case, the strongest and best-placed shoot should be selected, and all others at once cut off; otherwise, the progress of the specimens will be greatly retarded, and their symmetry destroyed. The terminal buds in the leading shoots of valuable young Conifers are often injured or destroyed by insects, and this is difficult to prevent, as the injury is mostly inflicted before it is observed. Birds will not unfrequently cause a like evil by repeatedly perching upon the end of the leading shoots, but this may be prevented by tying to the upper part of the trees a piece of wire, the upper end of which should be made exceedingly sharp, and this sharpened portion should extend an inch or two in advance of the terminal bud, which will effectually prevent birds from perching upon it. The very dry and hot weather which we are now experiencing is by no means favourable for the operation of budding *Roses* or other species of ornamental trees; but it should, nevertheless, be proceeded with on every favourable opportunity. In inserting buds in the Briar keep them as close to the stock as possible, as this lays the foundation of a well-formed head, and the shoots, when they grow, will appear to spring from the top of the stock. One of the best materials for binding the buds is coarse knitting cotton. Good soft bast, which should be wetted when about to be used, will also answer the purpose very well; but, whatever material may be used, the bud should be bound firmly above and below, so as to bring its base into close contact with the wood of the shoot it is budded on. All budding upon the Briar stock should, if possible, be accomplished during the present month, or early in the month of August; but it may be successfully performed on the *Manetti* stock up to the middle of September. Many other hardy trees and shrubs are perpetuated by means of budding, and the present is the proper time to attend to such matters. From some unknown causes, Nature not unfrequently develops abnormal sports, or *lusus nature*, of various forms, very frequently in deviation from the ordinary green colour of vegetation, or in the production of shoots or branches having coloured or variegated foliage; so that amateurs, and cultivators generally, should always be upon the outlook for such occurrences, and should take immediate advantage of the same, otherwise valuable and ornamental additions

to our hardy trees and shrubs, and to plants generally, would, and no doubt are, sometimes be lost to horticulture. So, whenever any striking or apparently valuable sport develops itself, it should be carefully encouraged; and, if produced by a hardy shrub or tree, the best and most rapid means of perpetuating and increasing the same is by budding it upon young plants of its normal or green-leaved congener. When sports are produced by tender or soft-wooded plants, they can generally be perpetuated by cuttings.—P. GRIEVE, *Culford Gardens, Bury St. Edmund's*.

Indoor Plant Department.

Give weak manure-water to gross feeding conservatory plants, and from specimens planted out in borders remove all superfluous shoots and suckers. *Tacsonias*, *Passifloras*, *Bignonias*, *Habrothamnuses*, *Loniceras*, *Maréchal Niel* *Roses*, and other climbers, must be frequently regulated in growth, not so much by means of shortening their shoots as by removing the weakest of them. *Fuchsias* trained to rafters require thinning, and *Clematides* tying to trellises. Do not allow deciduous climbers to intertwine with evergreen ones, as they are apt to spoil the latter. Keep up a succession of *Hydrangeas*, zonal, show, and sweet-scented *Pelargoniums*, *Fuchsias*, *Coleuses*, *Lobelias*, *Salvias*, *Cockscombs*, *Balsams*, *Schizanthuses*, and similar plants, and transfer to frames or the greenhouse such plants as have done flowering. Heaths, and some other early-flowering, hard-wooded plants, may now be set out of doors on a bed of ashes, plunging the pots in Cocoa-nut fibre, or some such material, to keep the roots cool and moist. In greenhouses, old plants of *Agapanthus umbellatus* will now be flowering abundantly, and should have plenty of water and a sunny position. Plants of *Hebeclinium ianthinum* should have been cut down after flowering, and should now be kept moderately dry for a time, unless it is necessary to force them early. Cut in hard-wooded *Veronicas* that have done blooming, so as to encourage fresh growth. Keep plants of *Lisianthus Russellianus* in a warm, moist place, and re-pot them as often as they require it. Pot off seedlings of *Primula japonica*, and keep them out-of-doors, where they form stronger plants than if nursed under glass. Shift *Statice* as they require it, and, when they begin to flower, give them manure-water, or place a mulching of manure over the surface of the soil in the pots in which they are growing. Lemon-scented *Verbenas* and *Fuchsias* should be started into growth, as required; those already started should be kept pinched in, to make them bushy. Plants of *Kalosanthes* should now have some assistance in the way of stimulants, as should also *Lilies*, and some soft-wooded plants. *Erythrias* in pots should be grown in a cool and light house near the glass; they require plenty of water, and their main branches should have supports of some kind to keep them in proper position. *Bouvardias* that were cut back after flowering should now be making good wood; they must, therefore, be kept moist and warm for some time yet. *Persian Cyclamens* should be kept in cool and shady frames, or against north walls; they should receive a little water during the summer months. *C. Coum*, and similar kinds, should also be kept moderately dry, but not too much so. *Azaleas* that have done blooming, and which have had their seed-pods picked off, should be re-potted, if necessary, and put into a warm pit, where heat, moisture, and shade can be given them. *Camellias* also make good growth under similar conditions, as do also *Citrons* of various kinds. Pinching-in should be practised freely until the plants have attained the form it is desired they should assume. Keep the atmosphere of stores moist by syringing not only the plants, but the stages and walls, and likewise by sprinkling the floor with water. *Poinsettias* should now be started into growth; they should be propagated by means of cuttings and eyes, and the young plants should be kept shifted on as they require it, and set near the glass. Plants of *Euphorbia jacquiniellora* must be kept growing, and also near the glass, so as to ripen the points of the shoots. Pot on young plants of *Sanchezia nobilis*, *Scutellaria Mocciniana* and *Ventenati*, *Pentas carnea*, *Linum trigynum*, *Monochaetum ensiferum*, *Centradenias*, *Eranthemums*, and others, using a compost of loam, thoroughly-decomposed manure, and a little peat. Increase the stock of *Achimenes* by means of cuttings; *Gloxinias*, by using good and well-developed leaves as cuttings; the fine-leaved *Begonias* in the same way as *Gloxinias*, and also by placing a whole leaf flat on the surface of a pan filled with silver sand and peat, and surfaced with sand, affixing the leaf thereon with pegs, cutting or breaking the ribs at intervals, and sprinkling some sand over the surface of the leaf; if kept damp and shaded, leaves treated in this way soon form buds at every break. The herbaceous kinds are best increased by means of cuttings. Keep *Epiphyllums* in a nice growing temperature, and *Encharis amazonica* plunged in bottom heat, in a moist stove and flooded with water. Pot seedlings of *Cyperus alternifolius*, give them plenty of heat and moisture, and they will form, when one or two years old, fine plants for table decoration. Keep *Dracenas*, *Crotons*, *Ananassas*, and other fine-leaved plants, near

the glass, in order to bring out their colours, but preserve them from strong sunshine. *Dipladenias*, *Allamandas*, and similarly habited plants, hitherto run along the roof just inside the glass, on threads, may be taken down as they come well into bloom, and trained so as to more fully exhibit their beauty. In the case of suspended baskets, remove any plants that appear to be exhausted, and replenish with fresh material; rather, however, than lift out many of the plants, plant the basket afresh, retaining such as are in good condition. Ferns, *Selaginellas*, *Tradescantias*, *Begonia scandens*, variegated *Panicum*, *Pittonias*, *Achimenes*, some of the creeping *Ficus*es, &c., do well in baskets kept in stores; and for conservatory and balcony baskets take Ivy-leaved and sweet-scented *Pelargonium*, brilliantly coloured *Lobelias* of the *Erinus* section, *Petunias*, *Mesembrianthemums* of different sorts, *Tropæolums*, *Isoplexis gracilis*, *Gazania splendens*, *Lysimachia nummularia*, *Ivies*, *Musk*, *Convolvulus mauritanicus*, and many kinds of Ferns and *Selaginella*.

Orchids.

Shading and watering now constitute the chief operations in the Orchid-house, and the cultivator will, in most cases, find it necessary to keep his plants well sponged over at least once a week, so as to keep red spider and thrips in subjection. Occasional syringings are very advantageous morning and evening during dry hot weather, and sundry fumigations with tobacco will be necessary to destroy green or yellow aphides, which rarely fail to put in an appearance either on the young growths or flower-spikes. The cool house must now be ventilated as much as possible, opening the doors on hot days and covering the openings with tiffany, which should be kept wet by repeated syringings; applications of this kind in the case of cool Orchids, deserve the attention of cultivators who often find their plants suffering from too much summer heat. The air is cooled as it passes through the wet tiffany, and the latter also serves to prevent draughts and dust.—F. W. BURMIDGE.

Indoor Fruit Department.

In early Pineries, in which the fruit has been cut, the planting material should be turned out, and the pits thoroughly cleansed and lime-washed. Suckers should be firmly potted into 6-inch pots, using fibry loam and a little charcoal for them; after being potted they should be either plunged in front of late succession plants or in separate beds, and shaded for a short time during bright sunshine. Vines swelling fruit should be allowed abundance of moisture, both at the root and in the atmosphere, and late Vine borders should receive good soakings of manure-water, either from the farmyard or the cesspool; immediately after the manure-water has been applied, another soaking of pure water should be given, in order to dilute the first application, and to wash it down. Figs should be allowed abundance of moisture at the root, overhead, and in the atmosphere. Stimulants should not be too often applied to Figs in the way of manure-water, but they thoroughly enjoy a mulching of good fibry loam and rotten manure. Peach and Nectarine trees that have done fruiting should be well syringed and supplied with water, and also freely exposed to the air. Melons that have done fruiting should be either thrown away and replaced by young ones, or cut back and encouraged to start anew; but young plants are best.

Hardy Fruit.

Complete as soon as possible the propagation of Strawberry plants for forcing and the forming of new Strawberry beds. Young plants pay best for growing. Some only fruit their plants once. They lay the earliest runners in pots, feed them freely throughout the season, plant them out on rich deep ground in the autumn, gather a fine crop, propagate fresh plants, and dig the one-year old ones in. This is carrying a sound principle to extremes. As a rule, the plants will carry more fruit the second year than the first, and they ought to be allowed to stand over for a second crop; unless, indeed, the almost better plan is adopted of forcing the young plants the first season, and then planting them out as soon as they have finished fruiting under glass. From such plants the first crop in open quarters is the best. Whether the liberal treatment in pots, the development of the leaves under glass and close to the light, and the abnormal strength thus thrown into the crowns, or the extraordinary activity and vigour of the roots, be the causes of the unusual fertility is uncertain; but, that it exists in forced plants, is proved afresh by each year's experience. The next best and most profitable method is to propagate plants, and treat them in every way as if intended for forcing, until the end of September, when they should be planted out on a bit of the best ground in the garden, in rows 2 or 2½ feet apart, the plants being 18 inches or 2 feet asunder in the rows. Another mode, involving less labour and the loss of a season in the age of the plants, is to remove the strongest runners as soon as rooted, plant them in beds or rows 6 inches apart, leave them there,

kept free of suckers, all flowers and fruit being picked off during the next season, and plant them out in the autumn as recommended for this year's strong plants. Such plants may also be allowed to fruit for one or two years. Two good crops, however, from the same plants, are as many as can be profitably taken from them. Attend to watering and mulching Strawberry plants turned out after forcing. These, properly cared for, will come in after the Elton Pine and other late sorts, and will carry the Strawberry season far into autumn. By planting fresh runners of Alpines or Hantboys every year, late Strawberries may also be gathered for ices. The Hantboys give a flavour unique among fruits, unless, indeed, a little of the same aroma may be detected in the American Musk Grapes or Mr. Pearson's hybrid Grape *Ferdinand de Lesseps*. It is most important to guard these late Strawberries from birds, and from too much sun. The latter burns out the quality, and flavour, as well as hurries the fruit over; whereas the object of the cultivator is to prolong it as late as possible. It is somewhat singular that cultivators, who do so much to get things early, take so little pains to have them late, though, to the true lover of Strawberries, these luscious fruits in September and October are just as much valued as in February or March. The late autumn-bearing Raspberries, if cut over by the ground, as they ought to have been last winter, will now require staking, as they will be coming into full bearing. Thin out the young canes of summer-bearing varieties, only leaving from three to five canes to a stool. Also cut out the bearing shoots as soon as the fruit is gathered, in order to admit more light and air to the young wood. If the latter is weak, it may be much strengthened by thoroughly soaking the roots with sewage, or surfacing with manure. The size and quantity of next year's crop will be determined by the vigour and size of the young wood produced and matured this autumn. Few fruits are in greater demand than Raspberries for preserves, and also for dessert, where they are liked; and few fruits pay better for liberal culture. The young canes, when strong, should also be loosely staked to protect them from being broken off by the winds. Should dry weather prevail, late Gooseberries and Currants will swell out finer and keep longer if they are well soaked with house sewage, and mulched over the roots with 6 inches of good manure. Net the fruit carefully from birds.—D. T. FISU.

Kitchen Garden.

Unless late Peas are heavily mulched and thoroughly watered two or three times a week, the crop is likely to be a scanty one. The advantages of sowing in well-manured trenches are now so apparent as to require no argument in favour of the general adoption of the plan for all Peas sown after the 1st of May, and, especially is this desirable in poor dry soils. Beyond a passing thunder storm, there is no likelihood at present of any considerable rainfall; sowing small seeds, therefore, will be useless, unless the ground is thoroughly soaked with water before sowing, and shaded immediately afterwards. In difficult seasons like the present, it will be better to make small sowings at more frequent intervals, and to pay particular attention to shading. Branches of Hazel, Ash, or Elm, may be obtained from the undergrowth in plantations almost everywhere without doing any permanent injury; and, although, the leaves will wither in a few hours, they will afterwards adhere to the branches a long time, and form a grateful shade to any crop just commencing growth, where frequent watering, if unaccompanied with frequent stirring of the surface, would render the soil almost impervious. Recently planted Celery would be much benefited during this scorching weather by being shaded with branches in this way; and, as they will permit an abundant circulation of air, there is no danger of the growth being weakened thereby. It is, in fact, necessary to adopt every expedient to check evaporation, and, as far as possible, to keep things in a growing condition, almost regardless of appearances. Early Potatoes are now ripe and may be lifted and stored at once; the tubers in consequence of the drought are smaller than usual, but are of good quality, without any symptoms of disease. Those intended for seed should be laid in an open shed with a northern aspect, where they will gradually become green, and in this condition they are capable of resisting a good deal of frost, and are less likely to make an exhausting and premature growth. During the winter they should be kept cool and in thin layers. The very best plan is to place them, at the approach of winter, "crown upwards," in shallow trays or boxes, one layer only in a tray. And there is no better place to keep those intended for early planting than under a greenhouse stage, where only sufficient artificial heat is used to keep out frost, and where, at all other times, an abundant circulation of air is admitted. Late Potatoes, that have not been injured by frost, and have consequently made sufficient growth to shade the ground, are at present looking well, but nearly everything, with the exception of grain crops, are suffering from the prolonged drought. Where it is desirable to plant a house of Cucumbers for

autumn use, a sufficient number of seeds of the Telegraph, or any other approved variety, may now be sown for that purpose. There is no necessity for any artificial heat at present. Soak the seeds in water for twelve or eighteen hours before sowing; plant each seed in a small 60-pot; shade, and keep close till the plants are up. Provide several more plants than will be required, and, when planting, select the strongest.—E. HODGAY.

Market Gardens.

The principal work in these now consists in stirring the surface of the soil about growing crops, and in gathering fruit. The principal crops at present ready for market are Cauliflowers, Cabbages, Peas, Broad and French Beans, Potatoes, Onions, Carrots, Vegetable Marrows, Cucumbers, Globe Artichokes, &c. Cucumbers producing heavy crops are assisted by applications of manure-water and guano-water; toads are kept in Cucumber-frames to keep down wood-lice. Vegetable Marrows are mulched. Tomatoes are now receiving close attention in the way of watering, for the retention of which drills are drawn on each side of the plants; they are also mulched with short dung. This crop is being deprived of all suckers and lateral shoots, preserving only the main stem, or at most only such shoots as are bearing good clusters of flowers or fruit. They are gone over every few days, thinned, and tied, the latter operation being performed so as to place them on the sunny side of the stakes. French Beans have begun to bear a fair crop. They are commonly grown in single lines from 2½ to 3 feet apart; between every alternate line is a row of Lettuces. The last sowing has just come up, and the ground about them is being loosened. Among Onions there is, as yet, little appearance of canker. Cauliflower ground that has become vacant is now hoed and afterwards loosened with a fork, but not turned over. The ground, after being loosened, is planted with Coleworts, about 11 or 15 inches apart each way. Good-sized plants are used for this purpose, as they do not yield so soon to the influence of drought. The first planted-out Celery, since the rains have come, is growing apace, and being in drills about 6 feet asunder, the sides of the ridges are broken with the hoe, so that a little of the soil may fall round the crowns. On the ridges, or rather curved spaces elevated to about 6 or 8 inches in the middle, are planted Lettuces or Coleworts for winter use. The Celery receives a good deluge of water now and then, and, if convenient, a little manure-water is likewise given to it. To Snow's Winter White Broccoli a little earth is being drawn; this is the kind that furnishes the early winter supply. Brussels Sprouts that were planted between lines of Potatoes, are now growing rapidly. Ground that has been occupied by the second and third crops of Lettuces, is again planted with a line of Savoys, and one of Lettuces alternately, the rows being about 14 or 15 inches apart. Gherkins are progressing favourably. Superfluous young wood on fruit trees on walls is being removed, and useless and unproductive old fruit bushes are uprooted and burned as soon as the fruit they have borne has been cleared off. Frames, hand-lights, &c., for next season's work are being painted, and otherwise put into thorough repair.

GARDEN PARTIES.

THE genius of the age, says the *Echo*, has discovered that in fresh sweet gardens, where stuffiness and over-breathed air are unknown, and where tea, ices, and Strawberries are tenfold more delicious than within doors, it is possible for the fortunate possessors to give parties where every social enjoyment may be had in perfection without any of the drawbacks which attend them when taken at night in heated rooms, and among flaring lights, at hours when every rational being ought to be asleep in bed. Of course it is but comparatively a few even among wealthy people who can offer such pleasures to their friends. Still we are persuaded that the great success of Garden Parties will have presented to our intelligent country-women something like a *beau idéal* to which assemblies ought to be made to approach as nearly as possible; and that a great deal will be done in consequence to make such gatherings more healthful and enjoyable. Few can open to their friends half an acre or so of close-shaven turf, sheltered with trees and adorned with roses, where easy chairs and Persian rugs, and tables, laden with services of coffee, ices and tea, make a score of groups, each worthy of Watteau. But hundreds might arrange (were such things to be well understood) that their rooms should open out with large French windows upon terraces or smaller gardens where the shade of two or three trees would be enough to give freshness. New houses of the handsomer sort would also be built in the suburbs, expressly with a view to possessing so great an attraction. Nor does it seem out of question that, as enterprising people have found it a good trade to let out ballrooms and dining-rooms, so others might keep a handsome, suitable garden in a convenient locality in the suburbs, which might be hired at will by

party givers, during the season, enabling them to offer their friends a far more charming entertainment than any indoors. Nor need we think of such pleasures as being confined to the rich. Have we not lately published a long string of requests for help in providing "a Day in the Country" for thousands of city-pent children. This is their Garden Party, and we hope that all of them will succeed in getting it. Very lately the Dean of Westminster gave to the exhibitors of Window Gardening what was practically a delightful Garden Party in the College Garden, and we hope his example may be followed by similar gatherings. The more we all herd together in smoky towns the more we need the repose and fresher air of gardens removed from the roar and rattle of the streets; and the more busy and anxious our lives, the more desirable it is that our pleasures should not be robbed from the hours when Nature needs sleep, and taken amid heated rooms and the sight-destroying glare of lamps, but enjoyed as veritable oases of greenness and freshness amid the wilderness wherein we dwell.

THE CURE OF ALKALI LANDS.

UPON the plains in our new territories on both sides of the Rocky Mountains, there are vast tracts of alkaline soils so much impregnated that they yield nothing but Sage brush and Grease wood, or are entirely barren. If cultivation is attempted, a white crust soon forms upon the surface, and all cultivated plants die. There are millions of acres of these lands rich in all the elements of plant food, but made worthless by the superabundance of alkali. It has been generally supposed that these lands could never be made productive. The settlers of Utah have been entirely successful in treating these lands, and have done a good work for the nation in demonstrating their great value. We some months ago visited the Jordan valley, and saw meadows with a thick heavy sod, yielding three tons of hay to the acre, that were once entirely barren. We also saw Wheat fields, that would turn fifty bushels to the acre, reclaimed by the same process. This matter has attracted the attention of the British Government, as they have large areas of similar lands in India, that they have never been able to make productive. The secret of success in reclaiming the land lies in a process of leaching the surface of the soil, more or less prolonged according to the quantity of alkali the soil contains. The field to be treated (of any convenient size) is first surrounded with a ditch about 3 feet deep, to carry off any water that may be run upon it at the upper edge. It is then laid off into strips about two rods wide by deep furrows running across the slope. The upper side of the furrow is ridged high enough to make a shallow pond covering the whole surface of the strip. The next breadth of the meadow is prepared in the same way, and so on until the whole is finished. Water is then taken from the irrigating ditch and turned into the upper basin, and this communicates with the lower basins until all are flooded. The water is allowed to stand for a few days in these shallow pools, when a frothy scum rises to the surface. It is then drawn off, carrying the scum with it, into the outside ditch. As this large ditch is lower than the surface, the water charged with alkali is all the while draining off through the soil. The water is kept running over this land summer and winter, for one or more years, according to its character. In some obstinate cases it is kept in the leach four or five years, before it will bear good crops. In others a single season will subdue it. The best crops for the first season after treatment are found to be Beans, Cotton, summer Squashes, Melons, and Onions. A few inches of sand spread over the surface is thought to have a beneficial influence, facilitating the germination of seed, and preventing the formation of crust. It is agreed by all parties who have reclaimed these soils that they are the most productive lands in the territory, bearing successive years of cropping without any apparent diminution of yield. In some parts of the territory they have succeeded in reclaiming these lands without irrigation, but this is where there is more rainfall than in the Jordan valley, and probably where there is less alkali in the soil. Heavy rainfall alone in some cases, has made the land productive. To facilitate the action of the rain the land is ploughed up and down the slope that the water may run off freely upon the surface. The land is ploughed frequently, and the particles undergo a change as they come in contact with the atmosphere, sun, rain, and frost. There are large tracts of these reclaimed lands in the territory yielding magnificent crops, and fine gardens and orchards loaded with fruit.—*American Agriculturist*.

THE following announcement appeared in a San Francisco paper:—"The gentleman who took, by mistake, a quantity of garden-hose from a residence in Geary Street, near Gough Street, is requested by the owner to call and get the nozzle, as the hose can be of no material use without it."

GARDENING NOMENCLATURE.

"What's in a name?" is a question that has often been raised, and, doubtless, as often settled—at least to the satisfaction of the questioner. Now, whether taken from the political, literary, social, or commercial point of view, there is, we apprehend, much in a name; and, if we descend from the general to the particular, we fancy that, from a horticultural point of view, it is not a matter of indifference. True it is that our greatest poet has said—

A Rose by any other name would smell as sweet;

but we take leave to doubt whether it would always seem as fair. We have observed that certain names at once take hold of the public, are in everyone's mouth, and make the novelty popular from the beginning; whereas, in other instances the reverse of this is the case, the high qualities of the novelty require knowing to make the name popular. If we look back on the past, or take the existing nomenclature of plants, we find much that is incongruous and in bad taste. Botanists and horticulturists have alike erred here. The former have transgressed by adopting a frightful terminology, by compounding words in different languages, and by applying words which do not correctly interpret facts. As an instance of the latter, the word "*coccinea*" (scarlet) is often applied to things crimson; "*cerulea*" (blue) to purple; and "*alba*" (white) to things which would hardly pass as such in the murky atmosphere of the sootiest towns. The horticulturist, even of our own time, too often gives the reins to fancy; and, after reading some of our plant catalogues, one would almost think that the days of bright blue Roses and luscious out-of-door Grapes had at length arrived. It may be pleasant enough, and sometimes temporarily profitable, to give the reins to fancy, when the practice not only amuses the mind, but, at the same time, fills the pockets of the performer. But there is a large and increasing class of amateur gardeners in the community, matter-of-fact people, to whom this method of proceeding is obnoxious. There is delusion in it. The purchaser acts, hopes, realises, and is disappointed. The object has not fairly answered the character given of it. We do not accuse the giver of these highly-coloured names of wilful exaggeration. The culture of flowers is not exactly that matter-of-fact occupation which some would represent it to be. There is poetry in it, and the ruddy glow of imagination will often unconsciously tinge the objects over which it delights to hover; but, if the names are applied with a poet's license, the descriptions should at least be precise, definite, and truthful. If horticulture is to become a science to the few, and remain a source of recreation to the many, its votaries must remember that even in poetry, and certainly in actual life, the imagination must be restrained within due bounds, or the result will be neither intelligible nor satisfactory. But these are not the only points on which reform is needed in the nomenclature of plants and flowers. Where is the cultivator who would not rejoice to see the long French names of Roses and other plants reduced to a state in which they might be spelt, pronounced, and understood by all? Could not the nurseryman into whose hands these novelties first pass translate such names as are translatable, and re-christen others? for many of such names are at present a mere jumble of unintelligible sounds to those who are the ofttest called on to repeat them. To prevent confusion, this work might be delegated to some tribunal whose authority would, by common consent, be acknowledged and followed. We once knew an ingenious labourer who remembered the name of the Rose "*Je me maintiendrai*" by assimilating it with the words "*Jenny maintain me*;" and we heard more than one philosophic nurseryman mourn over the loss of time incurred in writing "*Souvenir de la Reine d'Angleterre*," 500 time repeated, when "*Ajax*" or "*Imo*" would have answered every purpose. Further, something may be said on the fitness of names. A flower that would well become the name of "*Blushing Bride*" would make a very indifferent "*Alderman*;" nor should we expect to see exactly the same complexion in a "*Vulcan*" as in a "*Venus*." A large Gooseberry might appropriately bear the name of "*Achilles*," which would be far more euphonious and agreeable to ears polite than such names as "*Bang-up*" and "*Thumper*," which exist plentifully among this class of fruit. In this, however, as in other instances, we would not advocate a change of names already established—they are short and easy enough, if homely or provincial—but that future names be chosen from a more refined vocabulary. Finally, we have seen it somewhere suggested, and think the suggestion a good one, that newly-introduced species, the botanist's plants, should bear names coined from the Latin or Greek languages expressive of some prominent feature; and the horticulturalist's plants, what we are used to regard as mere variations of species, should have applied to them popular names in our own language. The names of the good and great ones of our own time, and of all time, offer for this purpose a rich repertory, from

which we might freely draw. These suggestive remarks are thrown out for the consideration of those who usually name our plants. There are a many cries for reform just now; and, among small things, it is nowhere more needed than in our horticultural nomenclature.—*Florist*.

Analyses of Guanos.—Dr. Voelcker has had transmitted to him, by the Secretary of the Admiralty, thirteen samples of guano, viz., five from Pabellon de Pica, three from Punta de Lobos, and five from Huanillos. In all cases these samples were taken from the deposits at various depths. The Pabellon guanos Dr. Voelcker describes as containing little moisture, and as in a fine powdery condition. In round numbers they contain from 8 to 13 per cent. of ammonia. They are inferior to Chinchá, but nearly equal to Guano-cope. The Punta de Lobos guano is drier than Guano-cope. The Huanillos guano is dry and powdery, of a light brown colour, and contains from 8 to 12½ per cent. of ammonia, and from 2½ to 6 per cent. of sand. One sample from Pabellon Dr. Voelcker compares favourably with the best old Chinchá guano.

Statues in London Squares.—There are several figures and effigies, particularly in the neighbourhoods of Trafalgar Square, Waterloo Place, and Hyde Park Corner, which the Metropolitan Board of Works would cover themselves with glory by buying up and removing to sequestered spots in the country—the heart of a forest, or the middle of a wood. Any little addition to the rates which such a judicious outlay might entail would, we are persuaded, be cheerfully borne by the inhabitants of the metropolis. Mr. Punch will be most happy to supply the Board with a list of desirable emigrants.—*Punch*.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

JULY 15TH.

THIS meeting, one of the best of the season, owed much of its excellence to the fruit prizes offered by Messrs. Veitch & Sons. Messrs. Carter & Co., too, added much to its interest by sending the finest collection of named varieties of Lettuces we have yet seen, as well as a fine series of dried specimen Peas. Mr. B. S. Williams had several groups of rare and choice decorative plants; and Messrs. Jackman staged a fine collection of hybrid Clematises.

Pelargoniums—These were well represented, and, on the whole, of good quality. The best collection came from Mr. Catling, gardener to Mrs. Lermite, of Finchley. It contained fine examples of good culture, some of the plants being nearly 4 feet through. The varieties were:—The Bride, white; Wm. Catlin, vivid scarlet; John Williams, salmon, and a perfect mass of bloom at least 4 feet across; Virgo Marie, white dark zone; Corsair, a splendid variety with compact trusses of fine vivid scarlet flowers; and Mons. Roudatier, bright salmon. This was one of the best plants in the show, and a dense shield of flowers nearly 5 feet through. The same exhibitor also had the best group of rosemary varieties. Mr. W. Paul, Mr. Chas. Turner, and others, staged excellent collections of golden and bronze Zonals, Ivy-leaved and other varieties; and the first named exhibitor also sent two excellent stands of cut flowers. In the case of new varieties, only one plant should be shown in the same pot, more than one, a practice sometimes resorted to, puzzling the public and conveying no correct idea of the true character or habit of the plant.

Fruit.—The show of fruit staged in competition for Messrs. Veitch's prizes, to which we have previously directed attention, was one of the best we ever remember to have seen at South Kensington of late years, and formed the chief attraction of the exhibition. It is once more evident that a good show of fruit is as possible as heretofore, if the prizes offered are sufficiently liberal, as they were on this occasion, to induce the best growers to cut their *finest* fruit. Mr. W. Coleman had a really fine collection of ten varieties, Black Hamburg Grapes and Royal George Peaches being unexceptionally fine and well-coloured, as was also a splendid dish of Lord Napier Nectarines. Rivers's Early Apricot, May Duke Cherries, and Brown Turkey Figs were also of excellent quality. Mr. G. T. Miles, gardener to Lord Carrington, also had a good collection, the Black Prince Grapes being excellent. In the same collection were fine Bellegarde Peaches, Violette Hative Nectarines, Jefferson Plums, and a fine dish of Strawberries, named Souvenir de Reefe. Mr. T. Jones, of Frogmore, also had a nice group; the excellence of the other dishes being somewhat marred by a faulty Pine. Mr. Baumerman, gardener to Lord Bagot, had a really fine group of six dishes, the Black Hamburg Grapes being very fine, as also were the Muscats, although not so perfectly finished as is desirable. The Royal George Peaches in this collection were nearly perfect in size, and richly coloured, the Nectarines and Figs being also of excellent quality. This was one of the most creditable collections staged, and well deserved the award it obtained. Mr. J. Watson also had a good assortment of fine fruit, the Grapes and Dr. Hogg Strawberries being excellent in every way. The last-named fruit is one of the largest and best for exhibition purposes, and always appears to bear packing and carriage well. Mr.

W. Bones had Black Hamburgh and Muscat Grapes in excellent condition, good Strawberries, and a nice Golden Queen Melon. Mr. D. Wilson, gardener to Earl Fortescue, staged ten fine Melons, to which an extra award was made. Mr. W. Sparkes had six very fine Queen Pines, to which an extra prize was given, while the best three Queens came from Mr. Stirling, Park Weir, Swansea, and Mr. D. Wilson was second with splendid smooth Cayennes. Grapes were well represented by fine large-berried clusters from Mr. Coleman, Mr. Deaville, Mr. London, and other well-known exhibitors. Mr. R. Fleming, Sandhays, Liverpool, staged three immense clusters of Black Hamburghs, the berries being too closely packed to allow them to swell properly; otherwise, they were splendid examples of good cultivation, and deservedly obtained an extra prize. The first prize for white Grapes was taken by Mr. London, who had Golden Champion, a really noble Grape, and a bunch of Muscat of Alexandria. Peaches were especially fine, there being about two dozen dishes staged, and all were above average quality. The varieties were Barrington, Belle-garde, Noblesse, Grosse Mignonne, Admirable, Royal George, and Teton de Venus, the latter being a large and fine fruit for table or exhibition purposes. Four splendid Queen Pines, weighing in all 19 lbs. 3 ozs., were placed before the fruit committee and awarded a certificate, these having, unfortunately, arrived too late for the fruit show. They were grown by Mr. Harris, gardener to Mrs. Vivian, Singleton, and were considered, by the entire committee, to be splendid examples of superior cultivation. Mr. Woodbridge, of Syon, sent fine specimens of Musa Champna, a variety from Trinidad. The fruit is about 3 or 4 inches in length, and thicker in proportion than that of *M. Cavendishii*. These were pronounced to be of excellent flavour. Mr. Perkins sent an Enville Queen Pine, rather irregular in shape, but weighing 8 lbs. 10 ozs. Melons, grown with their roots in water, came from Chatsworth, but were not considered to be of first-rate flavour. It was observed at the meeting that the best Melons in Persia are grown on floating islands or gardens, with their roots constantly in water; but that it is uninterrupted and bright hot sunlight which develops their flavour, much moisture at the root being essential to counteract the dryness of the air.

Miscellaneous Subjects.—Messrs. J. Veitch & Son sent a splendid group of new and rare decorative plants, among which a collection of new Gloxinias, with large and remarkably richly-coloured flowers, call for special notice. In this group was one of the finest plants of the beautiful blue *Vanda cœrulea* that we have ever seen, bearing a stout erect spike of about fourteen flowers, the individual blooms being not only large, but more vivid in colour than is generally seen. The plant was growing in a large teak cylinder, similar to that figured and described in *THE GARDEN* at p. 547, Vol. V. The collection also comprised a fine richly-coloured variety of *Aërides quinquevulnerum*, *Disa grandiflora*, *Croton Youngii*, remarkably brilliant in colour; *Darlingtonia californica*, *Sarracenia Stevensii*, which appears to be a vigorous habit, as well as a decidedly beautiful plant; *Ficus Parcellii*, *Tillandsia (Caraguata) Zahni*, and others equally interesting, to which a silver medal was awarded. Mr. B. S. Williams, of Holloway, also had a very effective group of stove and greenhouse plants, Ferns, and Orchids, including splendid specimens of *Aërides affine superbum*, with five or six fine spikes of rich rosy-purple flowers; *A. odoratum majus*, well-flowered; *Disa grandiflora*, the rare *Dendrobium crystallinum*, and others. This group was also deservedly honoured with a silver medal. Mr. J. Aldons obtained a bronze medal for a neat and tastefully-arranged bank of flowering and foliage decorative plants. The six Hydrangeas, shown by the same exhibitors, also deservedly obtained a first prize. It is surprising what an effective old plant this is when well grown, and as it is easily cultivated, even in a cottage window, it deserves to become even more generally popular, as a decorative plant, than is at present the case. Messrs. Veitch also had four splendid stands of cut Roses, the blooms being remarkably fresh and clean, and including some of the best of the old and new exhibition kinds; and a very interesting group of Conifers, growing in large tubs. Among the latter we noticed a fresh and healthy specimen of *Sciadopitys verticillata*, the curious and distinct Umbrella Pine from Japan. This is a striking plant, and is often depicted by Japanese artists on all kinds of ornamental articles. The same group also included some of the most beautiful of the *Retinosporas*, and a fine specimen of *Abies polita*, one of the rarest and most distinct in the whole group. Pinks, Carnations, Picotees, Verbenas, and other florists' flowers, were staged in capital condition by Mr. Charles Turner and other exhibitors. Mr. Jack, Battle Abbey, Sussex, sent cut spikes of the white-flowered *Maudevillea suaveolens* from a plant which has been growing planted out in the open air during the past fifteen years. Mr. G. F. Wilson sent a collection of Lilies, including *L. Humboldtii*, *L. longiflorum*, *L. umbellatum citratum*, a distinct variety of a deep salmon tint throughout, and *L. longiflorum marginatum*, with glaucous leaves, margined with clear creamy-white. Mr. G. Thomson, Crystal Palace Gardens, sent a fine hybrid form of the *L. lancifolium* type, the individual flowers being nearly as large as *L. auratum*, and of pearly whiteness, spotted with crimson. It is supposed to be the result of a cross between the last-named plant and *L. (lancifolium) speciosum*, and has previously been certificated as a first-class variety. Mr. P. Barr sent about thirty varieties from Tooting, including several fine forms not generally met with in cultivation. Messrs. Carter sent four pots of pyramidal-trained Lobelias, very healthy and well-flowered, and also cut specimens of a fine blue-flowered *Pentstemon*, unnamed. Mr. W. Paul sent a collection of double Zonal Pelargoniums, amongst which George Sand, a fine pale rose; Talabot, deep crimson; François Partusati, a rich salmon; and Jeanne Aléatière, a deep lilac-pink—deserve especial notice as being promising novelties. A fine robust plant of *Odontoglossum*

vexillarium, with ten flowers on two fine spikes, came from the Society's Garden. Mr. J. George, Putney Heath, sent four new Zonals with large bright flowers; and Mr. Perkins & Sons, Coventry, sent seedling Zonal Duchess of Edinburgh, a coarse grower with immense trusses of large white flowers with a salmon eye. Mr. Chitty, Stamford Hill, sent his new Coleus, Duchess of Edinburgh, to which we have before alluded as a fine plant. Messrs. E. G. Henderson sent Pelargonium Sparkler, a richly-coloured tricolor variety of good habit. Bridal Bouquet, a silver-edged variety with white flowers. Distinction, a dwarf dark Zonal variety with bright crimson-scarlet flowers in dense trusses; and Mrs. Maxwell Masters, a fine silver tricolor well coloured. The same firm also had a collection of new Ivy-leaved varieties with salmon and rosy-pink flowers. These are so valuable for hanging-baskets, window-boxes, and balconies, that we hope to see these new hybrids grown extensively for the latter purposes. A plant of a pretty rosy-flowered *Saccolabium*, named S. Cruikshankii, came from Messrs. Henderson; it has erect spikes and drooping fleshy leaves of a glaucous-green colour. A fine box of a new Rose named Miss Hassard came from Mr. C. Turner, who also had a fine stand of another new variety named Rev. J. B. Camm. The last-named is a fine full Rose with very fine foliage. Mr. Tipping, Richmond, sent a seedling golden zonal, resembling Golden Chain, named Golden Shower, which promises to be useful as a bedder. Mr. R. Dean, of Ealing, sent some fine cut spikes of many-coloured Stocks, cut Clove Pinks, Carnations, and Picotees, and three fine *Tropeolums*, the one named The Comet being remarkably dwarf, robust, and brilliant.

Vegetables.—Messrs. Carter & Co., High Holborn, sent forty-five varieties of Lettuce, many of which were of unusually fine quality, and all highly interesting in an horticultural point of view. Among them were Tom Thumb, well known as one of the best of the hearting or Cabbage Lettuces; Ne Plus Ultra and All the Year Round, both useful kinds, forming closely imbricating heads of fresh succulent leaves. The Hanson Lettuce is a novel American variety, with wonderfully fresh green succulent leaves forming a large head; this promises to be a decided acquisition. Other varieties consisted of Bath Cos, one of the very best for summer or market work. Paris white Cos, Paris green Cos, and others equally good. The same exhibitors sent a very interesting and useful collection of mounted specimens of their new Peas, each consisting of a single plant carefully dried and mounted to show the size and habit of growth, the fully-developed pod and ripe Peas being glued at the bottom. These give an excellent idea of the whole plant, and we understand Messrs. Carter intend to complete the collection as opportunities permit; and, at the same time, have offered to present them to the Society so that they may be available for future reference. Mr. Johnson, Glamis Castle, sent haulm and produce of Allen's Champion Pea, which, judging from the specimens sent, is a wonderful cropper, bearing large pods, each containing from ten to twelve Peas. Messrs. Burr & Sugden sent three boxes of very fine Cucumbers, including fresh well-grown specimens of Telegraph and Dyer's Champion, a more spiny variety, and rather longer in the specimens shown.

First-class Certificates were awarded to the following novelties:—

Double Pelargonium Jeannie Aligatière (W. Paul).—This is a fine habitated variety of free and vigorous growth, bearing large compact trusses of bright rosy flowers suffused with lilac. It is one of the best and most pleasing varieties of its class, and is well suited for pot culture or for cut flowers.

Pelargonium Zonal Sir Garnet Wolseley (George).—A free growing plant, with large compact trusses of vivid crimson-scarlet flowers.

Weeping Purple Birch (W. Paul).—This is a distinct form of the common Birch, and, like it, has a silvery trunk, while its foliage is of as deep a bronzy-purple as in the Purple Beech. It promises to become one of the very first of ornamental trees, and a worthy companion for the choicest of Conifers, and also for associating with variegated Negundos and other light-tinted ornamental-leaved trees.

× Ixora Fraseri (Fraser).—A robust variety of vigorous habit and deep glossy foliage, and immense heads of bright orange flowers fully 6 inches across. As a summer-flowering exhibition plant it deserves general culture.

× Campanula Smithii (Smith).—A pretty dwarf profuse flowering plant, supposed to be a hybrid between *C. Hostii* and *C. pulchra*, well adapted for pot culture and general decorative purposes. The flowers are nearly an inch across, erect, and of a beautiful bluish-lilac colour. The slender stems and foliage are densely covered with silky hairs.

Sonchella Hendersonii (Henderson).—A free fine-foliage stove plant, of dwarf growth, and resembling some of the *Bertolonias* in habit; the oblong serrated leaves are 3 to 5 inches in length, deep green, regularly spotted or blotched with silver grey. The under side of the leaves is purple, with darker veins and reticulation.

Sonchella Hendersonii argentea (Henderson).—Similar in habit to the last, of which it is a variety. The grey blotches here run together, and suffuse nearly the whole upper surface of the leaf; very distinct and beautiful.

H.P. Rose Royal Standard (C. Turner).—A fine full flower, densely incurved. It is of a deep rosy-lilac colour, and promises to become a splendid exhibition flower.

HORTICULTURAL SHOW AT CALAIS.

JULY 12TH AND 13TH.

On the occasion of the Calais *fête* the Société d'Agriculture offered prizes for the best culinary vegetables, to be exhibited in the Salon of the Hotel de Commerce, and the result was a very fair display, containing several features not common in English exhibitions of a similar kind. In the market gardens of St. Pierre, about one league from Calais, and at Cologne, on the road to Guines, where the soil is favourable to vegetable growing, some kinds are grown with eminent success, while others are strikingly inferior to the growths of our own gardens. Potatoes, in the light dry soil between Calais and Guines, and also in another direction between Calais and Dunkerque, on reclaimed land, appear to be

remarkably good, sound, and of large size; an English Kidney, Prince of Wales, was splendid, both in size and quality, some from private gardens being quite remarkable; a very pretty small Kidney, Achille Lemonnier for half the length and then white, was much admired. Early Cabbages, exhibited by the soldiers of the 8th regiment of the line, were exceedingly fine, and as a table vegetable were delicate; a much larger kind, grown at St. Pierre, by M. Demaisieux, all of a delicate pale green, even to the external leaves, and received the first prize. A great Cauliflower, Le Normand, quickly grown, and a foot across, crisp and tender, was a beautiful object for a gardener's eye to rest upon; and there were many other kinds equally fine, if not finer, to one of which the first prize was awarded. A great variety of Onions of distinct kinds, some of them very handsome bulbs, were shown. We do not, I think, grow the long purple Onion, *Corne de Boeuf*, which is much esteemed here, on account of its mild flavour, for soups and similar purposes; a large white kind, as white as snow, was a good deal noticed; and the *Oignon de Mader*, both flat and round, seemed to be of a good strain; as also a small round kind, nearly black, said to be very hardy and early. Several kinds of soup and stew herbs, not grown in England, are great favourites here. A delicate kind of Pea pleased me, it is as small as the seed of Sweet Pea when ripe, and I was informed that it is as sweet as sugar; it is called *Capucine-petit*. The ordinary pods of this miniature kind contain, on an average, eight to ten peas. The Carrots made a goodly show of both the long and short kinds, both red and white, principally grown for the table only; a yellow kind was of large size, and received honourable mention. Beet was in great variety, the purple kind being splendidly rich in colour; those with turnip-shaped roots are in much demand for stiff soils. The Kohl Rabi, on the other hand, cannot be favourably spoken of, nor can the Celery, the bundle to which the second prize was awarded being truly wretched. Turnips were well represented, and some of the varieties would, I fancy, be worth importing. The Navet de Tanden is a fine round root; and, among the long kinds, *Rose du Palatinat*, purple, half way down, and *Navet de Meaux*, a white kind, still longer in the roots, were remarkable, as well as the *Navet Jaune de Hollande*. There was *Scorzoneria* 20 inches long, which is a vegetable we ought to attend to more than we do; boiled in milk it is delicious. There was no *Cos Lettuce*, which in the neighbourhood of Paris is grown in such perfection; but, of the "Cabbage" kinds, there were the largest specimens I have ever seen. Early fruit was represented; but there was nothing remarkable. Two pot-grown Currant bushes, one white and one red, grown for table-decoration, received a first prize. The fruit was the largest I ever saw, and the branches were entirely clothed in such massive clusters that few table ornaments could be imagined of a more attractive and appropriate character. They were grown in square and very tasteful terra cotta pots, which were in themselves ornamental.

A TRAVELLING GARDENER.

THE BIRMINGHAM LAWN MOWER CONTEST.

THE following account of this trial has been kindly furnished us by one of the judges:—The place chosen for this trial was all that could be desired as regards space; but, in consequence of several large flower beds being dotted over it, it could not be staked out in a square workman-like manner. The trial, however, proved quite satisfactory, both to the judges and lookers on. Most of the machines were tried by the judges themselves, and every pains was taken to arrive at a just conclusion; indeed, Mr. Bennett, who was one of the judges, worked every machine entered for competition. The competitors were Messrs. Crowley & Co., Manchester; Messrs. Green & Son, Leeds; Messrs. Hartley & Sugden, Halifax; Mr. Harris, Birmingham; and Messrs. Barnard, Bishop, & Barnard, Norwich. The conditions under which the trial was to be made having been read, the contest commenced about a quarter to twelve o'clock. A 30-inch Green's new mower was first tried, worked by two men, and afterwards with a pony, but it failed to give satisfaction, inasmuch as it ribbed the Grass considerably; a 20-inch machine of the same pattern when tried was not more satisfactory; but the Silens Messor of the same make proved much better; but all the machines with chain action, more or less, ribbed the Grass. Messrs. Barnard & Bishop tried a 30-inch Ratchet with a pony, which made good work on level ground, but on uneven ground it also ribbed; this machine is very noisy, which certainly is a great drawback to it. Messrs. Hartley & Sugden's new machine, the Windsor, with flexible handles, was next tried, and it did its work tolerably well, but was hard to work. Edwards's Invincible, shown by Messrs. Crowley & Co., proved the easiest to use, and did its work remarkably well, making but little noise, and proved most satisfactory in the trial of various sizes. After a while, the whole of the machines were tried on wet Grass, with the same results in most cases as on dry lawn, the Invincible doing its work well, and throwing the Grass well forward. There is another advantage belonging to this machine, viz., the roller being placed behind the cutter, it is well adapted to cut long Grass. Unfortunately, there was no very long Grass on which to try the machines; but the trial took place on very satisfactory turf, with a close thick bottom. Messrs. Green's machines, having been better set, now cut much better, and proved easy as regards draught. All the makers regulated their own machines, but, in most cases, they were set too low to work easily. After the trial, which lasted four hours and a half, the judges had one of each of the machines taken to pieces, and the special merits claimed by each maker explained. After that, the awards were made as follows, viz., the gold medal to Messrs. Crowley & Co.; the silver medal to Mr. Harris for Green's Silens Messor (chain action); and the bronze medal to Messrs. Hartley & Sugden. After the awards were

made, the winning machine was purchased by one of the judges, and another of the same make was ordered by a second. Though Messrs. Shanks, Follows & Bate, and other well-known mowing machine makers did not compete, they all approved of the verdict which was arrived at. Messrs. Green & Son won the silver medal for a verge cutter.

OBITUARY.

THE LATE HENRY STEPHENS.

THE removal of an honoured veteran, in ripe old age, from the scene of his labours to the "rest that remaineth," need never be an occasion for sorrowful regret. And it is not so much for the purpose of paying his ashes the tribute of "one melodious tear," as for pointing the moral of an earnest man's example to survivors, that we draw attention to the career of usefulness just closed by the author of the "*Book of the Farm*," Mr. Henry Stephens, who died last week, in his eightieth year, at his residence, near Edinburgh. A Scotsman born and bred, he began life with a determination to devote himself to the theory and practice of agriculture; and it should be a lesson to the lads who look upon farming as a *definer resort*, when idle half years at school, and fruitless terms at college, result in a conviction that they are good for nothing else, and that the accessories of a farmer's life, the field-sports, the farmer's ordinaries, the riding, a good hack, and so forth, are "not so bad fun" after all. Mr. Stephens, as he has lucidly and plainly put it in the preface to his first edition of the "*Book of the Farm*," published in 1812, won a name in the pursuit to which he dedicated himself in a far more deliberate way. Having received a liberal education at the parochial and grammar schools of Dundee, and subsequently at the Universities of St. Andrews and Edinburgh, he boarded himself with one of the best Berwickshire farmers to acquire an insight into the best farming Scotland could show. Here for three years he pursued an "all-round" course of practical initiation with every species of farm-work, putting himself in the place of ploughman, shepherd, field-labourer, cattleman, and giving attention, at odd times, to the dairy and the poultry-house. Not content with this, he travelled abroad for eighteen months or so, at the close of the Peninsular war, by way of familiarising himself with whatever was in advance of our home system in continental agriculture. On returning to England he made his first and great experiment on what might have seemed a *corpus vile*, a neglected and dilapidated Forfarshire farm of 300 acres; but, what to his thoughtful and already experienced eye bespoke a future triumph over difficulties by dint of industry and perseverance. He straightened his fences, he drained his lands, and trench-ploughed them afterwards; he cultivated his wastes, he introduced improved sheep and cattle farming and housing, and, in short, he made a farm let at £150 a year worth £400. At this farm of Balmadies, a proud monument of determined industry and shrewd sense, he wrought till some forty years ago he migrated to near Edinburgh, and at Redbrae Cottage began the great work which has given him a European, as well as a Transatlantic reputation, such as no other agriculturist has attained in literature. The same thoroughness which characterised his practice, animated the pages in which, from the first elements to the most mature results of farming, he set down the history, system, and methods of successful agriculture. So simply, yet so clearly and ably has he detailed all the processes of British farming, that, although there is nothing to which the average British farmer is so averse as book-learning or pedantry, Stephens's "*Book of the Farm*" has ever been regarded as a justifiable book of reference, and an exception to the general rule of "unpractical theory," by even the most old-fashioned and anti-bookish farmers. After the first success of this *opus magnum*, it is not surprising that Mr. Stephens got many openings for collateral treatises on the subject, which he had made his own. In farm-buildings, farm-implements, farm-physiology, his authority associated him as a joint editor with others; and his "*Manual of Practical Draining and Catechism of Practical Agriculture*," as well as his "*Essay on Yester Deep Land Culture*" (1855) enhanced the reputation already acquired. But the most remarkable proof of Mr. Stephens's devotion to his favourite study was given in the last years of his life, when as late as 1871 he published a new edition of the "*Book of the Farm*," not simply revised and re-arranged, but actually recast and written, in order to bring up its contents to the latest developments of practical agriculture. Those who have compared the first edition with the last, as we have ourselves done, may well express amazement at the industry, candour, and receptivity of the old man, who could so keep himself *au courant* with the new improvement, which old age is apt to designate new-broomist, as to record seriatim the points of advance in each, and to weigh the merits of the old with the new, with all the impartiality of a judge. In his private life, Mr. Stephens was as simple and unpretending as he was genuine in his literary character. Honoured in public and in private, he was not set above himself by compliments or distinctions, but exhibited all the humble-mindedness of a real disciple of learning. He was hospitable and genial in his own quiet way, and enjoyed an occasional visit to his literary friends in the "modern Athens." Like all men of the same fibre and calibre, he had a keen interest in the events of the day—the new books, the current politics. One reads the same of the great James Watt, whose great intellect could embrace the common road of contemporary events, at the same time that it was grappling with the most abstruse problems of science. Long may it be ere this type of mankind fails before the coming-in of a more superficial system of study and acquirements. Long may Henry Stephens's example live with his "*Book of the Farm*."

THE GARDEN.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

THE SEASON AND OUR GARDENS.

THE proverbial vicissitudes of the weather in our fickle climate have, perhaps, never been more fully exemplified than during the present season, so far as great fluctuations between heat and cold, accompanied by excessive dryness, are concerned. Commencing with last autumn, it is not once in a quarter of a century that such a season for outdoor work occurs; all through the winter there was scarcely a day spoiled through frost, rain, or snow. Planting, whether associated with new work or alterations, went on uninterruptedly; through the absence of chilling rains or snow the ground never got so cold as usual, root-action scarcely being suspended. By the end of February and beginning of March, the continued dry weather, began to tell upon the water-supply, many wells being pumped dry daily, that had never been known to fail before, not even in the driest summers. The extremely mild winter, as might be supposed, brought fruit-trees early into bloom; yet, not so early as on some previous seasons. On the nights of the 9th, 10th, 11th, 12th, and 13th of March, we had respectively, 11°, 14°, 17°, 14°, and 7° of frost. Peaches, Apricots, and Nectarines, were in full bloom, and yet where protected with ordinary canvas covering the trees set a full crop, a circumstance which may be accounted for through two causes. First, the extraordinary dry state of the soil by which the sap in circulation was reduced to a minimum. Second, the concurrent dry state of the atmosphere; but I rather think that the dryness of the soil was the primary cause of their escape. During the last weeks of April we had a change to almost tropical weather, the thermometer in the shade reaching, as near as possible, to 80°, but this was of short duration. May brought us a return of cold unseasonable weather until near the end of the month, when we had it warmer, but throughout the month, as in April, there was an extraordinary absence of rain; the land, consequently, got very dry, all kitchen-garden crops being late and unpromising, except where more than ordinary means had been taken to assist them, or in exceptionally favoured spots. Deciduous timber trees were late in leafing, and their leaves uncommonly small in size, consequent not only upon the ungenial spring, but also upon the extremely dry state of the soil. June was characterised by alternate heat and cold, the thermometer ranging from 82° in the day down to freezing on several nights; this, as might be expected, had anything but a favourable effect upon tender things, such as Tomatoes, French Beans, and bedding plants. Roses in most places have been poor, their first growths having been cut off, and the second, as is usual in such cases, being weak. Thunder-showers were experienced in some parts of the country, but, on the whole, the amount of rainfall was exceedingly small. July brought us very hot weather, accompanied by thunder-storms, in some parts, and rain which was very partial—in some places abundant, in others little or none. We occasionally hear of gardeners who say they have discontinued watering kitchen-garden crops, depending on a liberal use of manure and deep culture to carry them through a dry season. In some unusually favourable localities, with a rich deep unctious loam resting on a naturally damp sub-soil, water may be dispensed with, but, in far the greater number of gardens, unless watering is resorted to in seasons like this, or even when the soil is not so dry as at present, it is vain to look for vegetables in either quantity or in condition fit to send to table, no matter how well the land is either prepared or cropped. In most places thoroughly good soakings, accompanied by mulchings, so as to prevent loss by evaporation, are necessary in very dry seasons, or the results are Peas all coming in together, and as hard as bullets before they are half grown, the late crops becoming a mass of white mildew, and not calculated to produce a single dish

when the season for which they were sown arrives; Cauli-flowers buttoning; Lettuce running to seed; and Celery bolting. This is precisely the condition in which many gardens are at present, where everything has been done in the preparation of the land and treatment of the crop that skill and attention could devise, except the application of water, which is not given for the best of all reasons, there being none to give. Wells, pumps, and cisterns having failed, every drop of water that is used has to be carted—in many places—a considerable distance. Such weather has not been favourable for the development and spread of the Potato fungus; consequently we have all but escaped the disease so far; but the excessively dry condition of the soil has, in many places, prematurely stopped the growth of the tubers, the eyes of which are just beginning to start, and as soon as we get rain in sufficient quantities to excite growth they will push a second crop, the effect of which will be to spoil their quality—this second produce being small and of little value. Where this state of matters exists, as soon as rain comes, and before they have had time to push this second growth, it is best to take up the crop, for, although they are not so good in quality or equal in weight to what they would have been if not checked in their growth, they will be better than if allowed to remain. Trees, such as Horse Chestnut, Elm, Lime, and Plane, are fast shedding their leaves as badly as Elms and Limes do in August, when much affected with red spider. Such seasons as the present show, in a marked degree, the mistake of allowing old trees to remain in too close proximity to each other, even in positions where it appears almost sacrilege to touch them. Wherever they happen to stand so close that the land cannot support them, particularly in respect to moisture at the roots, the result often is death. According to the laws of natural selection, the weakest perish, frequently leaving the survivors fatally injured in the death struggle; such seasons also point to the timely thinning of young trees, more especially such as stand in prominent positions before they get injured through insufficiency of food, consequent upon their being too closely planted. There are hundreds of bare unsightly spots in our parks, or grounds occupied by some newly-planted striplings, which have no chance of ever attaining the goodly proportions of the old trees they have supplanted. The latter might have weathered many a storm if the ground they occupied had not been exhausted by the continuous drain of too many roots. Old trees are like old animals: they have not the vigour of youth to sustain them in a life and death struggle; consequently, should never be allowed to stand too thickly. One living tree in such situations is vastly preferable to two dead ones. The weather too, has had the effect on insect life usual in such seasons. The hot days in April brought out wasps in this neighbourhood in large quantities. Such numbers then made their appearance as I do not recollect seeing so early in any previous season; but the recurrence of unseasonable cold evidently destroyed them, for, after the middle of May we scarcely saw one until within the last few days, when some have made their appearance. To some extent the same thing occurred with aphides. Through the mild winter they escaped destruction on Roses on walls and in similarly sheltered situations; the unusual heat of the few days in April brought to life quantities that were destroyed by the low temperature afterwards. Bad as the season has been for gardens, it might, nevertheless, have been worse for the country at large. Englishmen are proverbial grumblers at the weather. All through the spring we were lamenting the absence of rain, wherein, if the season had been wet instead of exceptionally dry, the earth temperature would have been so low that, combined with the low temperature of the air, it would have exercised a most damaging influence on vegetation, more especially upon that all-important crop—Wheat—which, instead of being as it is (exceptionally good), would have been a most serious failure. The way in which grain crops kept their colour, and went on growing through the unusually prolonged cold, was a subject of general remark, and an evidence of the mitigatory influence which a dry condition of the soil exercises over an ungenial state of the air.

T. BAINES.

Southgate.

NOTES OF THE WEEK.

— MR. J. T. BOSWELL SYME sends us, from his garden in Fifeshire, a healthy and vigorous branch in flower of a *Eucalyptus* which he thinks is *E. cordata*, and not *E. globulus* as stated last week (see p. 42). The leaves are bluntly heart-shaped, and rather closely set on the branches. Their colour is similar to that of the leaves of *E. globulus* and they are equally aromatic.

— *ABELIA FLORIBUNDA*, Mr. Charles Moore informs us, is now in fine flower at Glasnevin. It grows in the open air nailed against one of the houses and is very beautiful, its long purplish-red tubular blossoms being produced from the axils of the leaves at the ends of the branches in great profusion. It succeeds, we believe, out-of-doors in Devonshire, and in some of the other warmer counties in England.

— WE are pleased to be able to state that Lord and Lady Holmesdale have granted permission for the beautiful grounds at Linton Park to be open to visitors on Tuesday and Friday afternoons, from two to six o'clock, until further notice. A book will be kept in the conservatory, in which visitors will be invited to enter their names.

— WE learn, from the *Cultivator*, that many interesting facts were stated by members of the Michigan Pomological Society, from different parts of that State, showing the difference between the cold of low places, and the warmer temperature on hills and elevations, during the intense cold of winter—a difference of a hundred feet or two in height often making a difference of eight or ten degrees in temperature. Peaches were often found killed in low, warm places, while the trees bore plentiful crops on the hills above. This principle has been long well understood, but the additional corroborative evidence is interesting.

— PROF. BEAL lately gave an interesting address, with enlarged illustrations, on several characteristics which might be employed in describing fruits, which pomologists had overlooked. Among these was a dissimilarity in the form or aggregation of the styles in the flowers of some different sorts, but the most remarkable character which he pointed out was the peculiarity in the shape and markings of the petals of Apples, some being ovate, others round, cordate, &c., and so far as he had examined, these characteristics were constant or uniform. The only drawback for general utility is that they must be examined at a time when the fruit itself cannot be seen.

— IN reference to Chelsea Bridge and Battersea Park Sir C. Dilke asked the First Commissioner of Works, the other night, whether the subject of freeing from toll the government bridge leading to Battersea Park was under the consideration of the Office of Works, and whether the promise of that office to plant the vacant space on the west side of Battersea Park was to be carried out. Lord H. Lennox said the question of freeing Chelsea Bridge from toll was a difficult one, but he had hopes that the difficulty would not prove insuperable. With regard to the second part of the question, he said if Sir C. Dilke turns to the Estimates of this year, he will find that he had caused provision to be made in the Vote for Parks, &c., for the present year for forming and planting the empty space of ground on the west boundary of Battersea Park between the gymnasium and the west lodge. The work is in hand as far as the formation of the ground is concerned, and the planting will be commenced in the autumn.

— A COMPANY under the title of the Royal Aquarium and Summer and Winter Garden Society has been started, the object of which is to provide London with an aquarium and winter garden, and in connection therewith to afford facilities generally for the promotion of artistic, scientific, and musical entertainments. A site has been procured facing the Houses of Parliament and Westminster Abbey, and lying between the new Government offices and Victoria Street. The centre or main transepts of the building will be constructed principally of glass, forming a large conservatory and promenade surrounded by galleries. Special concerts (vocal and instrumental) will be held every Saturday, at which the most eminent and favourite artists will appear. Performances of an attractive and varied character will also take place on stated days; at Christmas an entertainment will be provided specially acceptable to children and families. The aquarium, says the prospectus, will be a special feature, being the first of its kind established in London; and no pains will be spared to render it at once the most complete and instructive aquarium in the world; the experience already gained in the construction and management of the Brighton, Crystal Palace, and Manchester aquaria will be fully utilised, and prove highly advantageous in the completion of the present enterprise. It may be specially noted that the marine aquarium has of late years proved one of the most attractive places of resort for all classes of society. In connection with the main building there will be rooms for private concerts and for the delivery of popular lectures on matters pertaining to science and art, and other subjects of public

interest. The hall will be so arranged that artistic, literary, and private societies can engage it for the purposes of meetings, conversations, &c.

— WE have received the official circular, relating to Mr. Gibson's testimonial, from the secretary, and have given it publicity in another column in the hope that it may receive the attention which it deserves.

— At the Lincolnshire County show, held this week at Grantham, Messrs. Carter's exhibition of seeds and roots formed a prominent feature, especially the display of Grass seeds and Grasses, a department to which much attention is evidently paid. They are shown in sets suitable for all kinds of soils and climate.

— THE operation of laying out the new park for Sheffield, given to that town by Mr. Mark Firth, of Oakbrook, has been commenced. The park is 36½ acres in extent, and commands one of the finest views to be had of the surrounding country. It is about two miles from Sheffield, and is near a densely populated part of that town.

— MR. JARLOR, the superintendent of street plantations in Paris, informs us that the Planes which we have been accustomed to admire in Paris, are beginning to suffer and to die. As soon as the roots get through the prepared soil, and touch the dry chalky Paris soil, they cease to thrive. On a recent visit to London, he was amazed at the size and beauty of the Planes and other deciduous trees in the west-central squares, and in other parts of London.

— *DISA GRANDIFLORA*, when well grown and flowered, amply repays all the trouble required for its successful cultivation. We saw, last week, at Sir William Marriott's garden, Down House, Dorset, some plants grown by his gardener (Mr. Hill) of this beautiful Orchid with more than eighty flowers in bloom at once. In one pan we counted more than thirty flowers of a most brilliantly coloured variety of *D. grandiflora*, named *superba*. Some of the varieties were originally given to Sir William Marriott, by Mr. Leach, of Clapham, whose skill in cultivating *D. grandiflora* is well known.

— WEST HAM PARK was opened on Monday last by the Mayor and Sheriffs of London. It has been partly the gift of Mr. Garney, partly of the Corporation of the City, and some of the expense has been raised by voluntary contributions. Altogether it is a magnificent gift of 80 acres of beautifully timbered land in the centre of a district which needs it sadly. In all, it is about some 5 acres larger than St. James's Park; and, though it lacks ornamental water, it makes up for that in the beauty of its Grass and trees. The whole formal ceremony of opening was a great success, and passed off with the greatest enthusiasm.

— ON Thursday last a flower show was held in the Drapers' Company's garden, Throgmorton Street, at which numerous prizes were awarded for window-plants grown within the precincts of the City. The plants exhibited consisted of *Aneubas*, Ivy, Zonal Pelargoniums, Musk, the Spotted and old Scarlet Monkey-flower (*Mimulus*), Creeping Jenny, Ferns—such as *Lastrea*, *Scolopendrium*, and *Adiantum*. A plant of the Canary Creeper (*Tropaeolum peregrinum*), came from St. Paul's Cathedral, and there were numerous examples of the fresh green *Ornithogalum*, an Onion-like bulb so often seen in cottager's windows in all parts both of town and country. The show was a very interesting one, and the plants staged good, considering the smoke and dust amid which they were grown. Mr. Marshall, of Enfield, sent a collection of choice Orchids and stove and greenhouse foliaged plants; while Messrs. W. Paul, C. Turner, and G. Paul & Sons, furnished admirable stands of cut Roses. The gardens are about an acre in extent (not several acres as stated at p. 20), and contain some fine old specimen Mulberry trees. In a large oval tank here, the white Water Lily grows luxuriantly, and the American water weed (*Anacharis*) is just now flowering very profusely.

— FINE specimens of Rhode Island Greenings were exhibited at a meeting of the Michigan Pomological Society, held on the 21st ult., as fresh and plump as in autumn, grown at South Haven, by President Phillips of the South Haven Horticultural Society. These Apples were packed in barrels with each specimen wrapped in paper, and headed up, and were kept in a cellar with a temperature near the freezing point through the winter. Handsome Apples thus packed brought 50 per cent. more in the market than those packed in the common way. Judge Ramsdell, of Traverse City, presented bright and fine specimens of several sorts grown at that place. Among them was the Fameuse, which appeared as fresh as in autumn. Specimens of the Golden Russet (of Western New-York) and Northern Spy were also in excellent condition, as well as Wagener and Baldwin. The Grand Traverse region is about 45° north, where Apples do not ripen till late in the season, and all sorts keep well. No warm weather occurs after the ripening season—a most important advantage. That region is nearly surrounded by the open waters of Lake Huron and Lake Michigan, and there is no difficulty in keeping Apples as low as 30° all winter.

THE INDOOR GARDEN.

LADY'S-SLIPPERS.

II.—Tender Cypripediums.

C. venustum (Handsome Lady's-slipper).—This is an old and well-known plant, with handsome foliage and rather showy green and purple flowers, which are copiously produced during the autumn and winter months. The flowers are nearly as large as those of the Bearded Lady's-slipper, but different in the foliage; and the lip is bronzy-green, not deep purple, as in the last-named plant. Close examination of the leaves shows them to be covered with a superposed layer of air-cells, and these give to the foliage a rather glaucous tint. It appears to like a tolerable degree of warmth; but I have seen creditable plants grown under ordinary greenhouse treatment. The sepals are white, or pale green, striped with darker lines at the base; and the spreading petals are olive-green at the base, having purple apices. They are fringed by rather long black hairs, and have a few black spots over their surface. It is an easily-grown plant, that should be in every collection of greenhouse or stove exotics. It is a native of the East Indies.—*C. venustum* Wall. Hook. Ex. Flora 35; Lod. Bot. Cab. 585; Bot. Reg. 10, 788; Bot. Mag. 47, 2,129.

C. venustum var. *spectabile* is a very distinct and bright coloured form, although very rare. There is an excellent coloured figure in the second volume of Warner's Select Orchidaceous Plants, t. 24.

C. pardium is a distinct variety of this plant, characterised by its broader foliage, having paler blotches of purple behind, and in the toe of the slipper being peculiarly obtuse or blunt. It often bears two, and more rarely three, flowers on a scape, the colours being similar to those of the normal form. It is figured in Floral Mag. 1874.

C. concolor (Self-coloured Lady's-slipper).—This is a small, but very distinct and interesting species. The flowers, which are of a clear sulphur-yellow throughout, sparingly dotted with brown, are borne on one or two flowered scapes from 2 to 5 inches in height, the flowers themselves being 2 or 3 inches across. It grows best in a warm moist stove or East Indian house, planted in a shallow pan of fibrous peat and lumps of sand or limestone rock. It flowers nearly continually when well grown, and requires plenty of moisture during the summer months. In winter, water very carefully, as it is inclined to rot off at the crown. The plant was discovered by the Rev. C. Parish on lime-stone rocks in Barmah. It is also a native of Moulmein, where, according to Colonel Benson, it is found on the exposed face of limestone rocks, under a burning sun for a considerable portion of the year.—*C. concolor*, Parish, M.S.; Bateman in Bot. Mag. t. 5,513; Gard. Chron. 1865, p. 626, with an excellent wood-cut fig.; Batm. 2d Cent. Or. Pl. t. 153.

C. niveum (Snow-white Lady's-slipper).—This is a little gem, and a general favourite wherever it is grown. In habit, it is so near the last, that Mr. Ellis, who obtained many of the first plants introduced, mistook it for *C. concolor* until it flowered. The foliage is, however, a little longer, and rather deeper in colour; the flowers are borne on one or two-flowered scapes, which vary from 3 to 6 inches in height, sometimes even higher; the sepals are white in front, suffused with delicate rose-flesh at the base, which gives them a charming opaline appearance, and at the back they are suffused with green, and blotched with dull purple; the sepals are pure white, nearly 2 inches long, and are dotted at the base with purple; lip, oblong, slightly pointed, not unlike a wren's egg, but larger, pure white, with minute purple dots. Like the last, it luxuriates best in a warm moist atmosphere, and thorough drainage at the root. Different individuals of this pretty little plant vary considerably in the form of the lip, some having the lip tapering and bluntly pointed, as in *C. concolor*; while others have it rounded, something like *C. Schlimmi*. It so nearly resembles *C. concolor* in all its parts, that I am inclined to think it is best considered as but a white form of that species.—*C. niveum* Rehb. f. in Gard. Chron. 1869, p. 1,038; *C. concolor* var. *niveum* Rehb. f. in litt.; Floral Mag. 1871, 513; Jennings's Orch. t. 28.

C. javanicum.—This is a very inconspicuous species of the *C. barbatum* type, having variegated foliage and solitary dingy green and purple flowers on a long slender purplish scape. It grows well treated like *C. barbatum*, and flowers during the winter months; its flowers, like all the others in this group, being very permanent in character. Although not showy, the plant is worth adding to a collection of these plants for variety. It is a native of Java and other islands in the Indian Archipelago.—*C. javanicum*, Reinw.; Flore des Serres, 7, 703.

C. barbatum (Bearded Lady's Slipper).—This is one of the best known and most generally cultivated of all the species. It is a most vigorous and free-flowering plant that may be had in bloom all throughout the year with but little trouble. The foliage is of a pleasing green colour, with darker blotches and lines, the flowers

being borne on long deep purple or chocolate-tinted scapes, 6 to 15 inches in height. The upper sepal is fully expanded, clear white at the apex, its lower half being striped with deep purple and bright green. The petals are spreading, and are of a bright purplish-tint, ciliated along their edges, and characterised by bright, hairy, black glands along their upper margins. The lip is quite an inch in width in good varieties and of a deep claret-purple, with deeper veins. This is one of the most variable plants in the whole group, the typical form being somewhat caulescent in character, with very small and poorly-coloured flowers. The best known variety in cultivation, and one of the most popular for show purposes, is *C. barbatum nigrum*, or, as it is sometimes called *superbum*. Another form, which bears two flowers on a scape, is named *C. barbatum biflorum*. *C. Crossii* is another very distinct form and rather rare. Strictly speaking, *C. Veitchii* (*superbiens*) and *C. Dayii* may be referred to this species, and all the numerous forms are easily recognised by the peculiar marginal glands on the petals, and the shape of the green staminode. The plant, being robust, readily adapts itself to very diverse modes of treatment. It grows well in turfy loam, peat, and dried cow-dung in shallow pans or pots, and, when well grown, makes a fine exhibition plant. For the latter purpose, it is a usual practice to grow the plants in small pots, and arrange those that bloom best in a large pan when in flower. Grouped in this way, and neatly surfaced with fresh moss, they have a fine effect in the eyes of ordinary floral critics, although they look stiff and formal to the artist. The plant is a native of Mount Ophir, a locality very interesting, as being the habitat of a beautiful, but, as yet, unintroduced Fern (*Mattonia pectinata*).—*C. barbatum* Lindl. Bot. Reg. 28, 17; Bot. Mag. 72, 4,234; Flor. de Serres, 3, 190. For fig. of *C. barbatum* v. *Crossii*, see La Belgique Hort., 1865, Nos. 8 and 9.

C. argus (Eye-like Spotted Lady's-slipper).—In habit this plant resembles *C. barbatum*, but the flowers are borne on taller scapes, the latter varying from 12 to 18 inches in height. The flowers are about the same size as in *C. barbatum*; sepals, white, streaked with green lines, as in *C. venustum*; petals, curved, as in *C. Fairieanum* and *C. vexillarium*, oblong, marked with green lines, and profusely spotted or blotched with deep purple eye-like markings; each petal has about seven large shining hairy glands along its upper margin, a character which shows its close relation to the bearded Lady-slipper in a marked degree. The blunt apices of the petals are suffused with purple as in *C. venustum*. Lip like that of *C. barbatum* in form, but veined with green on a bronze-coloured ground, as in *C. venustum*. It is a distinct and handsome plant, growing and flowering very freely in the winter and spring treated like its congeners. It was introduced by Messrs. Veitch, and first exhibited in December, 1873. It is a native of the Philippines, and may be a natural hybrid. Mr. Bateman suggests that *C. barbatum* and *C. venustum* are the parents, and in this opinion I fully agree. I believe it is not yet figured.—*C. argus* Rehb. f. in Gard. Chron., 1873, p. 608.

C. purpuratum.—This, at first sight, so closely resembles *C. barbatum*, both in habit and flower, that it is not unfrequently so named in gardens and nurseries. It is, however, very distinct, and characterised by the absence of marginal hairy glands, and by having the margins of the acute dorsal sepal or standard very distinctly revolute. It is an old species, seldom seen in modern collections, although I have noted it flowering annually in the Kew collection for several successive years. It blooms during the winter months, and lasts for fully a month or six weeks in perfection. It sometimes, though rarely, bears two flowers on a scape.—Lind. Bot. Reg. 23, 1,991; Wight Ic. Pl. Ind. or. 5, 1,780; Bot. Mag., t. 4,901.

C. Hookeri (Lady Hooker's Lady's-slipper).—This, although not remarkable for the beauty of its flowers, is a handsome plant, well worth growing as a foliage plant, its broad green foliage being conspicuously marked with silvery grey. Each leaf is from 4 to 6 inches long by about 2½ inches in width. The flowers are borne singly on scapes 12 to 16 inches in length; sepals, ovate, of a greenish-yellow colour; petals, 2 or 3 inches long, spatulate, green at the base, and of a lively purple colour at their apices, the petals are spotted with purple or brown about the centre; lip, more or less swollen, of a greenish-purple colour; staminode, oblong, greenish. This is the best of all the variegated kinds, and good varieties bear really handsome flowers, while others are very dingy. *C. Bullenii* is a variety of this plant. Like all the other tropical species, it likes plenty of subdued light and a warm moist atmosphere. This species and *C. Fairieanum* are subject to the attacks of thrips and red spider if irregularly treated, and these soon spoil their beauty and give them an unseemly rusty appearance. Genial warmth, fresh air, and moisture will do much to keep these pests in abeyance, especially if the syringe is freely used at the same time. It is a native of Borneo and the Malayan Archipelago.—Hook. Bot. Mag., t. 5,362; Batm. 2d. Cent. Orch. Pl. t. 123; Fl. des Serres, 15, 1,565.

C. superbicus (Superb Lady's-slipper), although nothing more than a fine form of the Bearded Lady's-slipper, this is, at the same time, so distinct and beautiful that for all garden purposes it merits a distinct title. The plant is easily recognised, even when not in flower, by its bright yellowish-green darkly-blotched foliage. Its flowers are large and solitary, borne on stout scapes, 12 to 14 inches high. The upper sepal is broadly egg-shaped, of a greenish shade at the base, softening into white at the tip, and streaked with deep green convergent lines. Petals 3 to 3½ inches long, nearly an inch broad, strap-shaped, rather blunt at their points, and deflexed at an angle of about 45°. The petals are white, shading into green at the base, the apices being tinted with rose. The petals are spotted throughout with deep purple, something in the way of *C. argus*; but here the markings are smaller and the segments larger. The lip is large, inflated at the mouth, tapering in graceful curves to a blunt point, being of a dull purplish brown colour, veined with green at the sides. The stamina are lunulate, with a tooth on each side below. It likes a very warm humid atmosphere, and a fresh open compost, and appears to grow nearly all the year, so that it should not want for moisture at any time. It is a native of Java, often called *C. Veitchii* in gardens.—Rehb. f. in Bonplandia, 1855, 227; Xenia Orch. ii. 9, t. 103; Warner Select. Orch. Ser. 2, t. 12; L. Ill. Hort. 12, 429.

C. Dayanum (Mr. John Day's Lady's-slipper).—This is another fine and distinct form of the ubiquitous *C. barbatum*, and as one of the most effective of its class, should find a place in the most select collection. In form, the flower reminds one of *C. superbicus*, but it is easily distinguished from that form by the dorsal sepal being narrower and more sharply pointed; the petals are longer and more spreading, and are not spotted. The upper segment is ovate, pale yellowish-white, streaked with green; petals 3 to 4 inches in length, white at the tips, pale green at the base, streaked with interrupted brownish purple lines. Lips very large and wide at the mouth, gradually curving to a bluntness point as in *C. superbicus*, the colour being purplish-brown, margined with a shade of green. Foliage, light green, blotched irregularly with a darker shade. It has a tolerably free habit, and requires a warm fresh humid atmosphere, with a copious supply of tepid moisture at the root. Flowered first about 1860. It is a native of Borneo and the Malayan Archipelago. Although described as *C. spectabile*, it must not be confounded with the hardy North American species of that name.—*C. spectabile*, Rehb. in Allg. Gart. Zeit., Oct. 11, 1856, var. Dayii; *C. spectabile*, Gard. Chron. 1860, p. 695; Flor. de Serres, listed in as *C. Dayii*.

C. insigne (Bannered Lady's-slipper).—This is one of the oldest and best of all the species, and one that grows well with the same care as is requisite to succeed with a *Fuchsia* or *Geranium*. It is one of the best and most suitable of all greenhouse Orchids, for it must be badly treated, indeed, if it refuses to grow and bloom. It likes a compost of fibrous loam and well-dried cowdung on a well-drained bottom, with plenty of water at the foot when growing; blooming, as it does in the winter, makes this doubly valuable. A very fine variety of this plant, with brighter-coloured flowers and more white on the upper sepal, is called *Maulei*. A good figure of this variety will be found in *Flore des Serres* 15, 1561. As an Orchid for room or window-culture in a Wardian case, this has no equal, as it is perfectly safe if preserved from actual frost, although the nearer the winter temperature is kept at 10° Far. the better. It should never be allowed to become thoroughly dry at the root, though less moisture is desirable during dull or cold weather, or the plant may suffer from damp. In the *Gardeners' Chronicle*, 1812, p. 253, a correspondent recommends this as a drawing-room decorative plant, when in flower, and says:—"On the 1st of December I placed eight plants in the drawing-room; there they revelled in the greatest luxuriance for three successive months, and, when taken out in March, were as fresh and vigorous as the day they were put in."—Wall. Hook. Ex. Fl. 34; Lodd. Cab. 1,321; Bot. Mag., 62, 3, 112. The figure under this name in B. Bumph., 195, is *C. glanduliferum* of the same author. *C. insigne Veitchianum*.—This is a still finer variety than *C. Maulei*, the upper sepal being large and white nearly to the base, profusely blotched with crimson. A plant of this was sold in the Meadowbank collection for over twenty guineas. I believe it is not yet figured.

C. villosum (Shaggy Lady's-slipper).—One of the finest and most luxuriant of all the species, which grows equally well either in a hot stove or in a cool Orchid-house. Coming from the hot climate of Moulmein, one would expect a high temperature was essential to its well-being; but such is not the case—indeed, the plants seem fresher and more vigorous when grown in a cool, moist, airy temperature than when coddled up in the East Indian-house. The foliage is of a fresh green colour, the base behind being profusely speckled with purple; flowers, solitary, on stout hairy scapes, 6 to 2 inches in height; sepals, oblong, greenish, shaded and streaked with brown towards the base; the spatulate petals are of a bright brown tint,

shining as if varnished; the lip is of a pale yellow tint, shaded with purplish brown, and shining like the petals; the oblong staminode is honey-coloured, slightly tinged with green, having a blunt tooth or a projecting tubercle in the centre; well-grown specimens bear twenty to thirty flowers, and last six weeks in perfection. This is one of the best species an amateur can add to his collection, as it seldom fails to please. A native of India-Moulmein, where it was found by Mr. T. Lobb, one of the most successful of the Veitchian collectors, at an elevation of 5,000 feet.—Lindl. in Gard. Chron. 1854, p. 135.

C. hirsutissimum (Hairy Lady's-slipper).—A free-growing plant, bearing large fully-expanded flowers on scapes shorter than the leaves. Although not particularly showy, it deserves culture as a variety, especially as it blooms freely at the dull season of the year, when flowers of any kind are valuable; flowers, solitary, the sepals being green, shaded with dull brown, the petals having undulated margins, and a partial twist near their apices, green at the base, profusely dotted with brown, and of a bright purple tint at the apex; lip, green, very profusely spotted with brown. This species was first published by Hooker in the *Botanical Magazine*, from Lindley's manuscripts, and the plant first flowered in English collections about 1858. Lindley remarks that it is allied to *C. insigne*, *villosum*, *Lowii*, and *barbatum*, which species he thus distinguishes from each other:—"C. insigne is only tomentose, and its petals want the spatulate form, long hairs, and strong undulation. C. villosum has longer flowers, no undulation, or beard, or ciliation of the petals, and has the sterile stamen truncate, not quadrate. Of C. Lowii, the long flat naked petals are quite different. C. barbatum has a circular, not quadrate, sterile stamen, spotted short leaves, and wants the shagreeness. In C. purpuratum the sterile stamen is lunate." The plant is a native of Assam.—Lindl. Bot. Mag., t. 1999; Warner's Select Orch. Pl., 1st ser., t. 15; Batm. 2nd Cent. Orch. Pl., t. 119.

C. Fairieanum (Mr. Fairie's Lady's-slipper).—One of the rarest and most distinct plants in the group, easily recognised when in bloom by the rich purple markings on its dorsal sepal, and by the curious double curve assumed by the petals. The plant is rather small in habit, having pale greenish leaves that spread horizontally over the top of the shallow pan in which it should be grown. It is rather delicate, and likes a warm partially shaded position in the East Indian-house or plant stove, with a fresh open sandy compost thoroughly well drained. The flowers are solitary on slender scapes, the upper sepal being large in proportion to the other segments, the margins being undulate and pilose or ciliate, while at the apex striped with rich purple or claret markings. The lower sepal is greenish-white and much smaller; petals, curved downwards, green striped with purple, margined with purple hairs. The plant was first described by Lindley from a specimen which first bloomed with Mr. Fairie, of Liverpool, in 1857. The plant was first imported from Assam; and, although many consignments have been received, it continues very rare. It blooms in the autumn and lasts well.—Hook. in Bot. Mag., t. 5,024; Gard. Chron., 1857, p. 701; Batm. 2nd Cent. Orch. Pl., t. 119.

C. Lowii (Mr. Hugh Low's Lady's-slipper).—This is a strong-growing vigorous-habited species, introduced in 1816, and was described soon after from a specimen which bloomed in the collection of A. Kenrich, Esq., of West Bromwich. It is a native of Borneo, where it is found growing on the branches of some of the highest forest trees. I have seen some finely-grown plants in the garden of Provost Russel, of Mayfield, near Falkirk, N.B., who has one of the best and most complete collections of these curious and beautiful plants that I have ever seen. One of these plants bore six flowers on a fine scape nearly 4 feet long. The foliage is about 12 to 14 inches long, and 1½ inches in width, of a dark green colour, the erect scape being usually about 2 feet high and three to four flowered. The upper sepal is downy at the back and pale green within. The petals are 3 to 4 inches long, projected nearly horizontally at right angles with the lip. These are spatulate in form, yellowish-green at the base, heavily spotted or blotched with purple, the apices being of a dullish purple tint; the lip is oblong, blunt at the apex, of a shining purplish-brown colour; the staminode is curiously three-lobed below. This plant, although a native of one of the hottest and most universally humid districts in the world, grows perfectly well in a moderately cool Cattleya-house. They grow best in a fresh open turfy compost surfaced with living *Sphagnum Moss*, into which its thick hairy roots branch in all directions. This plant is more rarely known as *C. cruciforme*. It is a native of Borneo.—*Flore des Serres* 4, 375; Jour. Hort. Soc. 5, 27; Lindl. in Gard. Chron., 1817, p. 765, with wood-cut fig.

C. Schlummi (Schlimm's Lady's-slipper).—This is a charming little plant when well grown, yet growers, as a rule, fail in its cultivation. I have only seen two plants in a really first-class condition, one in Provost Russel's well-known collection at Falkirk, and the other in Mr. Edwin Wrigley's garden at Bury, Lancashire. The last mentioned specimen had leaves 12 to 16 inches in length and nearly

2 inches broad, being of a frosh light green colour, and in the most vigorous health. It was growing with *Odontogloss*, *Disas*, and *Oncidium macranthum*, in a cool moist house, and was literally revelling in a fresh open compost of turfy loam and fibrous peat, surfaced with living *Sphagnum Moss*. It bears pretty little flowers 1 to 2 inches across, on erect simple, or more rarely branched, spikes. The sepals are oblong, slightly downy, and greenish white; petals, oval or oblong, pure white, sometimes sparingly spotted with bright purple; lip, rounded, white, suffused with bright rose. The flowers are not unlike those of the North American *C. spectabile* in shape and colour, but smaller. It is very liable to the attacks of thrips, which seem especially fond of its fresh succulent young leaves; a cool atmosphere, regular supplies of moisture at the root, together with daily syringings, and a shady position in the house, will do much to prevent their ravages. It is a chaste little species well worth culture. It is a native of New Grenada, and flowered with Mr. Bull about 1866. — *Bot. Mag.*, t. 5,614

C. caudatum (Long-tailed *Cypripede*).—This is one of the most attractive of Orchids, and, at the same time, one of the greatest curiosities of the vegetable kingdom. The foliage is strap-shaped, 5 to 10 inches in length by about 1 inch wide, and of a bright green colour. The spike is two or three flowered, and is a little longer than the leaves. The flowers are large and handsome; sepals, ovate-alternate, the lower one rather larger than the upper one, 3 or 4 inches in length, and of a pale yellowish colour, streaked with deep green markings, and sometimes tinged with rose. The lip is large and very much swollen, yellowish outside, heavily suffused with greenish-purple. The colouring is very rich in the best forms. The inflected lobes at the base are of ivory whiteness, spotted with rich purple markings. The petals are the most striking parts of the flower and are remarkable not only for their great length, but for the gradual manner in which they elongate until the maximum length of from 20 to 30 inches is attained. When the buds first open these petals are not much longer than the sepals, but they continue to increase in length, for nine or ten days at least, after the flower opens. It would be interesting to know the cause of their rapid growth, while, at the same time, the rest of the flower does not visibly enlarge; it is, however, a peculiarity evinced, more or less, by all the long-petalled *Cypripedes* and by one or two *Brassias*. Another case, nearly similar, is found in the tail or spur of *Angraecum sesquipedale*, which frequently attains the length of from 12 to 16 inches. It was pointed out by Darwin, in his "Fertilisation of Orchids," that in its native habitat (Madagascar) there probably existed a lepidopterous insect with a proboscis sufficiently long to reach the nectar, which is secreted at the very bottom of the tube or nectary, and suggested that its so doing resulted in the fertilisation of the flower. More recently this has been proved to be the case, and a moth has been discovered in the island with a proboscis of the required length. In the case of the Long-tailed Lady's-slipper I have often thought that it might possibly be fertilised in Peru by large ants or other creatures unable to fly, and that the long petals served as ladders up which they can climb to the sexual apparatus. It is one of the best species in the

genus and should be introduced to every collection. *C. caudatum roseum*, is a brighter coloured variety which succeeds well under rather cooler treatment than the normal type. This plant grows well in a cool Orchid-house where the temperature is kept about 40° in winter, and is very effective. *C. caudatum* first flowered in the once celebrated collection of Mrs. Lawrence at Ealing Park in 1850. Native of the Peruvian Andes.—*Lindl. Hook.*, t. c. pl., 7, 658-9; *Pact. Fl. Gard.*, 9; *Flor des Serres*, 6, 566; *Warner's Orch. Plants* 2nd series, t. 1.

C. Stonei (Mr. Stone's Lady's-slipper).—This may be considered as one of the most attractive species in the whole group. It was first imported from Sarawak by Messrs. Hugh Low & Co., and named in honour of Mr. Stone, an enthusiastic cultivator and late gardener to Mr. Day, of Tottenham. It has smooth foliage of a bright green colour, about 1 foot in length, and 1½ to 2 inches in width. The flowers are borne 2 to 4 together, on a large curved erect spike, subtended by large bracts. The flowers are large and brightly coloured; sepals, white, faintly tinged with rose, and heavily blotched behind with purple; petals, 5 inches long, and ½ of an inch broad, drooping, slightly twisted, of a faint yellow colour, streaked and blotched with purple; lip, not unlike a Mahomedan slipper in shape; of a bright rosy-lilac colour, with conspicuous carmine-tinted veins. The style is curiously two-branched, and the staminode is surrounded by a hairy border, like the collar of a Polish tunic. A fine variety of this, *C. Stonei platytanum*, differs from the normal form in having flat petals fully ½ to ¾ of an inch broad, richly blotched with purple. It is both rare and valuable.—*C. Stonei*, *Lindl.*, *Bot. Mag.*, t. 5,349; *Batm.* 2d Cent. Or. Pl. 200; *Jenning's Orch.* t. 12; *C. Stonei platytanum* *Rehb. f. Gard. Chron.*, 1867, p. 1,118, with excellent wood-cut fig.

C. levigatum (Glossy-leaved Lady's-slipper).—In habit this is barely distinguishable from *C. Stonei*, and their mode of flowering is the same. It is easily distinguished, however, by its smaller flowers, and by the purple markings in front of the ovate dorsal sepal, as well as the scape ovaries, bracts, and petals of the present plant being profusely covered with purple hairs, while in *C. Stonei* they are perfectly smooth. The petals are also much more distinctly twisted, and vary from 4 to 6 inches in length, being of a clear yellow colour, streaked

and spotted with purple at the base; the lip is yellow, shaded with purple. This beautiful plant was introduced from the Philippine Islands by the late Mr. John Gould Veitch, who discovered it growing on the roots of *Vanda Batemanii*. Like its congener, *C. Stonei*, this only succeeds well in a warm genial atmosphere, partially shaded during bright sunshine, with plenty of light during the dull autumn and winter months. Good specimens of both these beautiful plants bear from three to six fine spikes, each bearing three or four flowers.—*C. levigatum* (*Bateman*), *Bot. Mag.*, t. 5,508; *Batm.* 2d Cent. Or. Pl. t. 101; *Flora des Serres* 17, 1860.

C. caricinum (Ledge-leaved Lady's-slipper).—This is a modest slender-leaved little plant, well worth growing in a mixed collection. Its bright green grassy leaves are produced from a slender rhizome which creeps over the surface of the mossy compost in all directions

Cypripedium Fairieanum.

Its flowers are borne on erect spikes, one to three together, and, though not showy, are extremely delicate in their tinting, and the narrow petals are curiously tortile or twisted like a fanciful corkscrew. Sepals and lip of a pale grass-like green hue; petals, greenish, margined with white, and tipped with purplish-brown. It flowered in Messrs. Veitch's Orchid-houses in 1865, and is one of Mr. Pearce's discoveries. It grows well in a moderately cool and humid temperature, with copious supplies of moisture at the root. I have seen this plant growing vigorously and flowering most profusely in a cool lean-to Orchid-house, with air on night and day in summer. Treated in this manner, this species and the pretty little *C. Schlimmii* do well; both like to feel the effects of condensed moisture on their fresh foliage during the night. It is a native of Peru and Bolivia, and is sometimes known as *C. Pearcei*, as a compliment to its unfortunate discoverer.—*Bot. Mag.*, t. 5, 166.

C. glanduliferum (Blume's glandular-petalled Lady's-slipper).—This is a rare and curious plant, not at present introduced to our collections. It bears large handsome flowers, two or three together on a scape. Petals, 3 or 4 inches in length, acute or sharp pointed, and bearing two or three conspicuous hairy glands along their margins; lip, inflated, pink or bright rose-coloured, with a pair of reversed horn-like appendages inside. It agrees with *C. Parishii*, in having long petals set with large hairy glands, but the petals of the last-named have blunt rounded hairy apices, by which it may readily be distinguished. The only figure I have seen is in "*Blume's Rumphia*," Vol. IV., 198, where it is figured under the name of *C. insigne*, which must not be confounded with the well-known *C. insigne* of Wallich. It is also known as *C. glanduliferum*. Native of New Guinea, and probably also of Java.

C. Parishii (Rev. C. S. Parish's Cypripede, or the Elephant-crushed Lady's-slipper).—This is a very interesting plant, with broadly strap-shaped deep green leaves bifid at the tip. The flower-spoke is 1 to 2 feet long, bearing from three to five large long-petalled flowers; the upper sepal is ovate, with unfolded margins, and has a strongly defined reel behind; the lower sepal is rather smaller and reflexed; in colour they are pale greenish-yellow. The petals are 4 to 6 inches long, with undulated margins near the base, and the segments become distinctly twisted towards the rounded hairy tips. They are greenish-yellow at the base, margined with purple, while the apical portion is deep claret-purple, with pale margins; each petal has about three hazy marginal glands, the lip is oblong, with the lower lobes inflexed in the usual way, the colour being a decided green, shaded with brown. It grows well in a warm genial atmosphere, and has recently been exhibited by Mr. B. S. Williams, at South Kensington. The only other Lady's-slipper that has the peculiar large hairy glands on its long petals is the *C. glanduliferum*, of New Guinea, and that has not the curious blunt tips to its petals like our plant. The plant was introduced by the Rev. C. S. Parish, who met with it in India, near the Siamese frontier.—*C. Parishii*, *Rehb. f. in MS. in litt*; *R. C. Parish in Herb. Kew*; in *Flora*, June, 1869; *Gard. Chron.* 1869, p. 814; *Bot. Mag.*, t. 5, 791.

C. longifolium (Long-leaved or Reichenbach's Lady's-slipper).—This is a free-growing species, introduced by M. Roetz, one of the most intrepid and successful of modern collectors. According to Reichenbach, this plant, *C. Roetzii*, *C. caudatum*, *C. Pearcei*, *C. Schlimmii*, and one or two others, all South American, belong to *Selinipedium*, a genus characterised by having a three-celled ovary. The foliage of this plant is bright green, strap-shaped, 12 to 16 inches long, by 1 to 1½ inches broad. The scape varies from 2 to 4 feet long, bearing ten to twelve or more flowers, which open in gradual succession from below upwards, rarely more than one being open at the same time; in this way a plant often lasts in bloom for a whole year or more. The flowers are of a warm yellowish-green tint, shaded with brown, each having a large green bract at the base. The drooping or divergent petals are 3 or 4 inches long, tapering from the base, where they are half an inch broad, to the attenuated apices. These are of a brownish-purple colour, the lower sepal is much the largest, a very unusual occurrence in the genus, although well marked in the present species, and in *C. Roetzii*. These segments are of a greenish-brown colour, the lip being oblong, olive-green in front, and profusely dotted or speckled within. The rhomboidal, or triangular, staminode has a conspicuous rim of stiff black hairs along its upper margins. It grows well in a moderate temperature. This is also, though erroneously, known as *Reichenbachii* in some gardens. A native of Costa Rica.—*C. longifolium*, *Rehb. f.*, 1869, p. 1, 266.

C. Roetzii (Roetz's Lady's-slipper).—This is a very robust plant, very nearly related to the long-leaved Cypripede, but distinguishable by its much longer and broader foliage, and by its flowers being larger and much more showy. The leaves vary from 12 to 18 inches in length, being nearly 2 inches wide, and of the freshest green colour imaginable. It grows freely treated like its congeners. The spike, like that of the last-named, is 2 to 4 feet long, with great

Strelitzia-like bracts at the base of each flower. The flowers open in gradual succession, rarely more than two being open at the same time, and the plant continues flowering for ten or even twelve months from the same spike. The sepals are ovate and of a soft rosy tint, the lower being nearly twice the size of the upper segment. The petals are 3 or 4 inches long, and of a bright rosy-purple colour; the lip is green, shaded with purplish-brown. The inflexed sides being pale yellow, profusely warted, and having about two green glands on each side about the centre. It is a noble plant that should be included in every collection. Uplands in South America.

C. japonicum (Japanese Lady's-slipper).—This is a rare and extremely slow growing plant, which I have never seen in cultivation. It is a native of Japan.—*C. japonicum*, Thunberg's *Icon. Jap.* t. 1.

C. Sedenii (M. Seden's Cypripede).—This is a very beautiful hybrid, and very vivid in its colouring. It was raised by Mr. Seden, one of the foremen in the Royal Exotic Nursery, at Chelsea, and is the result of a cross between *C. Schlimmii* and *C. longifolium*. It is an interesting fact that the plants were intercrossed with each other, and seedlings raised from both; the species, as seed-bearing parents, gave exactly the same results. The foliage is strap-shaped, gracefully curved, and of a bright green colour. Flower-spikes, purple, hairy, bearing five to seven flowers each, only one or two being fully expanded at the same time. The sepals are oblong, of a bright rosy colour. Petals, oblong, inclined to be strap-shaped, and partially twisted near the apex, creamy-white with deep rosy margins; lip, oblong, bluntly pointed, the mouth being curiously lobed on each side, and having rounded bosses on the front margin. The inflexed sides are pure white, dotted with rose, the staminode being slightly downy and tinted with pale yellow. It flowers very freely throughout the winter, and its bright foliage and brilliant flowers make it a general favourite. Grows well in a cool house.—*Jenning's Orchids*, t. 4; *C. Sedenii*, *Rehb. f. in Gard. Chron.* 1873, p. 1, 085.

C. Harrissianum (Dr. Harris's Lady-slipper).—This is a very robust free-growing hybrid, raised by Mr. Dominy between *C. villosum* and *C. barbatum*. The leaves are 5 to 7 inches long, nearly 2 inches broad, and are of a bright green colour, marked with darker green in the way of *C. barbatum*; flowers, large, shining, as if varnished, shaped something like those of the first named parent, but darker in colour, the lip is rich purple, the petals being shaded with purple and brown. It grows and blooms nearly all the year round, and is one of the finest plants in the whole group. Some forms are deeper and brighter in colour, but all are good and well worth culture in the most select collection.—*C. Harrissianum*, *Rehb. f. in Gard. Chron.*, 1869, p. 108.

C. veillarium (Standard Lady's-slipper).—This is another beautiful plant raised in Messrs. Veitch's establishment at Chelsea. It has variegated foliage and is the result of a cross between *C. barbatum* and the pretty little *C. Fairianum*. The result is a very interesting hybrid nearly exactly intermediate in character between the two species; the dorsal sepal is roundish-oblong, with undulate hairy margins, of a light greenish tint veined with purple; petals, curved like those of the last-named plant, hairy along the margins, pale green in colour, with dark veins and purple spots and markings; lip, purple, shaded with green. It flowers during the winter months, and is well deserving of general culture.—*Rehb. f. in Gard. Chron.* 1870, p. 1, 373.

C. Domonii (Mr. Dominy's Cypripede).—This is a free-growing plant with the general habit of *C. caudatum*, except that the leaves are narrower and more gracefully curved. It is the produce of seed from the last-named plant fertilised with *C. caricinum*, and the flowers, although closely resembling *C. caudatum* in form and size, show traces of both parents; the sepals are light green shaded with dark green, the drooping twisted petals being of a pale yellow tint streaked with bright reddish crimson; the inflexed lobes of the lip are pure white with rich claret-coloured dots, while the sac-shaped central lobe is green, heavily shaded with purplish-brown. It is a most desirable plant, blooming during the winter and spring months, and lasting a long time in beauty if the flowers are kept dry.—*Rehb. f. in Gard. Chron.* 1870, p. 1, 181.

C. Ashburtonia.—This plant is the result of a cross between the old Bannered Lady's-slipper and the well-known *C. barbatum*. In habit and inflorescence it somewhat resembles both parents. The leaves are shaped like those of *C. insigne*, but are a little broader, bifid at the tip, and covered with dark net-like markings of dark green on a lighter ground. Some individuals are marked nearly as distinctly a *C. barbatum*, while, in others, the markings are barely visible. The flowers are in shape similar to those of the last-named, and are borne singly on a slender chocolate-coloured scape about a foot high. Upper sepal white at the apex, greenish at the base, having numerous deep brownish-purple stripes and blotches; petals slightly deflexed, oblong, wavy along their margins, of a greenish-white with deep purplish veins; the margins being hairy and tinged

with purplish-rose. Lip oblong, rather blunt at the point, and narrowing towards the mouth; the colour is greenish, shaded with purple, the depth of colour varying in different individuals. It is an interesting and easily grown plant, well worth growing. It was raised by Mr. Cross, late gardener to Lady Asburton, at Melchet Park, Hampshire, after whom it is named.—*C. Ashburtoniae*, Rehb. fil. Gard. Chron., 1871, p. 1,617, where there is a woodcut figure.

C. Crossianum (Mr. Cross's Lady's-slipper).—This is another pleasing hybrid, raised at the same time as the last, and from the same parents. Its oblong foliage is intermediate between that of *C. insigne* and *C. venustum*, being of a glaucous-green tint above, paler below, blotched with purplish-black towards the base. There are a few dark reticulations on the upper surface of the leaf. The flowers are borne on purple hairy scapes, 8 to 12 inches in length; the bract being glaucous, with purple spots; upper sepal, white at the apex, pale green below, with dark green nerves, and a few purple spots at the base; petals, strap-shaped, slightly wavy, of a brownish copper colour, with dark purple or blackish spots; the lip is yellowish, shaded with bronze, and having the green net-work as in *C. venustum*; the stamens are like *C. venustum* in form, but of a yellow or pale honey colour, as in *C. insigne*. It is an interesting plant, and must not be confounded with *C. barbatum* Crossii.—*C. Crossianum* Rehb. f. in Gard. Chron. 1873, p. 877.

Uropedium Lindenii (Linden's Uropede).—This curious and extremely rare plant was named by the late Dr. J. Lindley, one of the most distinguished and acute of all orchidologists. It grows well in a cool house, and was introduced to our collections in 1818 by M. Linden, after whom it is named. As a genus this differs from *Cypripedium* of Linnæus or *Selinipedium* of Reichenbach, by having an elongated petaloid appendage, in place of the swollen slipper-shaped lip. In habit and mode of flowering, the plant is identical with *C. caudatum*, and the flowers closely resemble those of the last-named plant in every respect, except in the slipper being transformed into a long caudal appendage. It does well treated like *C. caudatum*. The plant flowers in the spring and may be regarded as a monstrous form of the last-named species. It is a native of New Granada, where it grows sparingly in moist woods at an altitude of 7,000 to 8,500 feet, and where the mean annual temperature is only 56°. It first flowered with M. Pescatore, of St. Cloud, near Paris, in 1853.—*Uropedium Lindenii*, Lindl., Belg. Hort. 4, 13; Regel. Gartenfl., 1861, 315. F. W. B.

New Golden Fern (*Gymnogramma decomposita*).—As a garden plant, this new Golden Fern will take the position of a companion to the silvery *G. pulchella*, the size, fine cutting, and triangular outline of the fronds, producing a certain amount of similarity, though botanically the two are perfectly distinct. It was introduced from the Andes of South America, by John Gair, Esq., of Falkirk, by whom it was sent to Kew, and from thence it has been distributed. The fronds are nearly deltoid in outline, membranous in texture, and quadripinnatifid in division, supported on dark chestnut-brown shining stiples more than a foot long, clothed with sulphury meal at the base, and furnished with a few scattered pale brown scales. The pinnae are set on tolerably close, of a clear green colour, the pinnules close lanceolate-deltoid, the tertiary segments palmatifidly cut down into linear-acute segments, and bearing the sulphur-yellow sori through the whole length of the vein. It is a fine stove species, the large triangular fronds having a peculiarly elegant appearance from their fine cutting, while the minute finger-like divisions into which the lobes are split up give it a distinctive character.—*Florist*.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Crinum asiaticum.—This has bright green leaves of a fresh glossy green, and the flowers are white and delicately perfumed, twenty or thirty being borne on each scape. They are succeeded by great pale green globular fruits, not unlike small Apples, and these, even after the flowers are over, give the plant a striking appearance.—J. D. K.

Leuchtenbergia principis.—A fine healthy specimen of this rare succulent is now showing flower in the succulent-house at Kew. The plant has peculiar elongated angular mamme, from the apices of which the flowers appear. It is a plant but rarely seen, although last year it bloomed well in Mr. Peacock's collection at Hammersmith.

Crasula Saxifraga.—This pretty tuberous-rooted species has been recently figured in the *Botanical Magazine* (see t. 6, 668). Its rounded crenulate leaves are deep green above and of a lively rosy-carmine beneath. The flowers are of a pale rose colour, and are borne in a small dense cyme at the apex of the peduncles, from 4 to 6 inches in height. It is now in flower at Kew, and deserves a place in every collection of succulent plants.—B.

Fuchsia Seed.—A person visiting a Fuchsia-house, on one of the Continental seed farms, was asked to guess the weight of seed procured from the house—about 10 by 30 feet in size. Twenty, ten, and even as little as one pound were suggested, but the fact proved that the entire product was only one quarter of an ounce. Mr. Cannell's specimen Fuchsia-house, 30 feet by 20 feet, has not yet afforded him a quarter of an ounce in one season.

NOTES FROM THE LEVANT.

HAVING lately returned from a short tour in the Levant, during which I paid some attention to the horticulture and wild flowers of the countries which I visited a few notes on what I saw may perhaps be of interest to the readers of THE GARDEN. My intention was to have visited the islands of Crete and Cyprus, and the south coast of Asia Minor; but, various causes having prevented my carrying out this plan, I took the French steamer from Marseilles on March 6, for Smyrna. Though we called at both Palermo and Messina, I had no time on shore at either place to collect plants, or to see anything of the natural productions of Sicily. A hurried walk through the public gardens at Palermo showed that the climate must be a remarkably fine one; for, though the spring was said to be unusually backward, and snow was lying on the mountains at 3,000 feet above the sea, Irises and Roses were both coming into flower on March 9. Date Palms, Magnolias, Loquats, and Oranges were very fine in these gardens; and a good many plants, which in England are usually kept in a warm greenhouse, such as Cannas, Caladiums, Cycas revoluta, two or three species of Araucaria, and others, were thriving in the open air. The botanic gardens here are said to be very interesting, and much better cared for than many Italian botanic gardens; but, as it was getting dark when I landed, I had not time to visit them. A month or so in Sicily would probably repay a lover of flowers extremely well; for, having a greater variety of climate than any other island in the Mediterranean, a very rich soil, and a great diversity of natural features, its flora is extremely rich and varied. Two days after leaving Sicily the steamer arrived at Syra, one of the principal islands in the Greek Archipelago, and the seat of a large and prosperous trade. As we had to remain three hours, I took the opportunity of getting on shore, and walked up to the top of the hill above the town, which is about 1,200 to 1,500 feet high. Having always supposed that the climate of the Greek islands was, even in winter, a warm one, I was greatly astonished to see snow lying on all the islands, which were more than 2,000 feet high. By the middle of March, spring is usually at its height here; but this winter seems to have been one of unusual severity all over the Levant, and I hear that the streets of Athens and Smyrna have, within a few days, been almost blocked with snow. Syra, like most of the Greek islands, looks from a short distance extremely barren and rocky; but, wherever any soil has accumulated in valleys or in hollows in the rocks, which are tolerably sheltered from the high winds, Corn, Vines, and fruit trees are cultivated. The most abundant and conspicuous plants are *Asphodelus ramosus*, *Scilla maritima*, and *Poterium spinosum*, a curious-looking herb with branching spines. A yellow-flowered *Genista* was also coming into bloom, notwithstanding the cold; whilst *Anemones*, *Grape Hyacinths*, and a small bulbous *Iris* (*Xiphium sisyrinchium*) starred the ground with patches of colour. On ascending a few hundred feet, the Squills and *Asphodel* became more stunted; and near the top I found a species of *Crocus* in seed, probably *C. Fleischeri*, a small *Romulea*, a *Colchicum*, and other dwarf bulbs, all in a very starved condition, owing to the absence of soil. What there was is stiff red loam without any sand, formed by the decomposition of limestone rock. It is in such a soil, I may observe, that most of the mountain plants I collected in Asia Minor grow, including nearly all the *Croci*; and Herbert mentions the same thing with regard to the *Croci* he found in the Ionian Islands. The only one which I have found in a sandy soil is *C. sativus*; but, though they can resist the immense heat on these islands, they grow much stronger when slightly protected from the sun. The gardens of Syra seem very poor, as, owing to the great scarcity of water for irrigation, not many vegetables or flowers are grown. Figs, Peaches, Prickly Pears, and Grapes seem to be the principal fruits, as I saw neither Oranges or Olives. I arrived at Smyrna on March 12, in a heavy storm of wind and rain, and found much snow lying on all the mountains round. Everyone is talking of the unusual severity of the weather, and judging from the look of the trees, they have good reason to complain, for many of the Oranges are so cut by the cold that they will hardly get over it. Strolling up the hill at the back of the town, not a flower was to be seen, but a small pink *Erodium*, just showing

above ground. Outside Smyrna, as is usual in most Turkish towns, are large cemeteries planted with Cypresses of great age and height. This species, *Cupressus fastigiata*, is hardly seen in perfection, except in a Turkish cemetery, though as an individual tree, the finest I have ever seen is in the garden of Mr. Whittall, at Bournabat, near Smyrna. This tree is a perfect model of health and symmetry. Though at least 80 feet high, and very old, it is so perfectly furnished from top to bottom with branches, that there is not in the whole tree a bare or irregular place to be seen; the fellow tree to it, on the other side of the entrance, was unfortunately blown down, but the one that remains still acts as a noble sentinel at the gate of one of the best known, and most hospitable houses near Smyrna. During the week I remained at Smyrna, the weather continued very bad, heavy snow on the mountains and rain on the coast, so after making two or three excursions in the neighbourhood, I saw that very little could be done at present in the way of collecting flowers. I found, however, at last three species of *Crocus*, two *Trichonemas*, and a few other bulbous plants coming into bloom. The soil of the plains round Smyrna, is a very rich deep loam, and where water can be obtained for irrigation will grow almost any kind of crop in perfection. Wheat, Vines, Maize, and Cotton are the principal crops of the country, but the wine produced is not of good quality, though strong and cheap. I have never tasted in any part of the Levant wine that I really liked, most of the sorts being too strong and sweet to drink, unless mixed with at least as much water. Whether this is on account of the soil and climate, or the way of making the wine, I am not sure, but probably the great heat and richness of the soil has something to do with it. Almost all kinds of fruit grow well near Smyrna, especially Pomegranates, Apples, Peaches, Grapes, and Apricots. The Pomagranates of Bounarbashi, are very celebrated, and really are far superior to any I have eaten elsewhere. In the month of March and April they still keep fresh and are wonderfully sweet and juicy. The hills round Smyrna are of limestone, very barren and stony, and covered in most parts with a scrub of dwarf or evergreen Oak, *Cistus*, and other shrubs. Pines grow on the higher parts of the hills in scattered woods, but few deciduous trees seem to grow here. Oleanders and Myrtles fill the beds of all the streams and water courses, the former growing to a height of 12 or 15 feet. Before leaving Smyrna, I made an expedition to Ephesus, where I found vegetation rather more advanced than at the former place. The hills here were covered with an immense species of *Fernia*, the dead flower-stalks of which were 7 or 8 feet high, and 2 inches in diameter. Two sorts of *Asphodel* were also very abundant, and some interesting succulent plants, Ferns, and creepers were found in the rocky chasms of the hill on which the ruins mostly stand. In more shady parts of these gullies the ground was perfectly covered with the leaves of *Cyclamen hederifolium* growing with a vigour I have never seen elsewhere. Some of the corms I took up were not less than 6 inches in diameter, but so deeply buried in black leaf-mould that they were not easy to get up. *Cyclamens* are called Sowbread in Turkey, as well as in Europe, but I do not think the name is a well-founded one, as though wild pigs are abundant in many parts of the country. I never saw the marks of their rooting where *Cyclamens* grew. One of the most beautiful trees for its size in Europe, *Arbutus andrachne*, is common on the hill sides near Ephesus and in many parts of Turkey. The smooth bark resembles red Russia leather, covered with a thin silvery skin, which peels off in winter. The flowers are produced in April in large white panicles, and which give the tree a most elegant appearance, and make it a worthy ornament for an English lawn. On March 21st I left Smyrna in a small English steamer, which calls at various places on the coast of Asia Minor, intending to land at Maeri, in Lycia, a very beautiful and little-known part of Asia Minor, which offers greater attractions to the naturalist, sportsman, antiquarian, or artist, than any country I have been in except the Himalaya. On the way we touched at Scio, a very fertile island, where Mastic, a spirit very much drunk by Greeks all over the east, is principally made.

Samos, a good-sized island, which produces some of the best wine in the Levant, was the next calling place, and here I had time for a hurried run on shore. Spring was at least fifteen

days in advance of Smyrna, and many flowers were out; among them gorgeous *Anemones*, *Trichonemas*, *Cerinthas*, *Chrysanthemums*, and three sorts of Ferns, *Adiantum Capillus Veneris*, *Ceterach officinarum*, and *Nothochlæna Marantæ*. The Vines were just bursting their buds, and all looked very inviting for an exploration of the island, which having mountains of 3,000 and 4,000 feet high is sure to contain some fine plants. Early next morning we were at C'os, an island which has the largest extent of level ground I have seen in the archipelago. Here there is a celebrated Plane tree, which, however, did not appear to me so fine as some I have seen in Macedonia and on the Bosphorus. It is, as usual in Turkish towns, carefully preserved on account of the shade, which is, in these sunny islands, so valuable. Symi was the next island where I landed; a barren rock, producing hardly anything but sponges, which are collected by the inhabitants of Symi and Caylmo in different parts of the Levant, and brought here to be dried and manipulated. The natives of these islands are wonderfully expert in diving, being able to reach the bottom in as much as 30 fathoms of water, and to remain down nearly two minutes. After landing in the harbour of the thriving little town, I went up the hill-side, which I found perfectly covered with the most lovely Persian *Cyclamens* in full flower. They were growing in the crevices and on the ledges of hard sharp white limestone rocks, the soil being a stiff red loam; and though the corms were smaller than we grow in greenhouses, I never saw finer flowers or better marked leaves than on these stony barren islands.

(To be continued.) H. J. ELWES.

How to Withstand the Heat.—Under this heading the *Lancet* gives some seasonable advice which none require more than those who pass their time in gardens on these sunny days. About this season of the year we commonly receive various communications, some asking for and others tendering advice to the public as to the best methods of avoiding sunstroke. The necessary precautions are, after all, such as common sense would dictate. Temperate living, light and loose clothing, proper protection for the head, a cold bath in the morning, and the avoidance of that excitable fussiness as to the heat of the weather, which so many persons exhibit to the increase of their own and other people's discomfort. Veritable cases of sunstroke do occur in this country, of course; but the majority of such attacks, especially when fatal, are probably attributable to the combined effects of heat and languor and some pre-existing affection of the circulatory or respiratory organs. A condition, which is in reality more allied to fainting than to sunstroke, may overtake those who encounter heat and fatigue, with long intervals of abstinence from food; and the same thing is very apt to follow in those persons who have deranged their digestion and overloaded their systems by a course of dinners. Young and healthy men do not require any stimulants; they can refresh and cool themselves with any iced non-alcoholic drinks, or with iced claret and water. A great desideratum is a really palatable and cool beverage free from alcohol. After dry and hot seasons, when choleraic and febrile complaints are likely to occur, many people begin to manifest a hydrophobia without any antecedent bite of a rabid dog, for they are not at all confident as to the quality of any drinking water, even if it were procurable in a fresh pleasant state at refreshment rooms. In the case of middle-aged and older men, who, from being occupied in town, are very apt to abstain from taking anything during the day, and to forget, perhaps, that their appetite for breakfast in hot weather is small, we think a very light mid-day meal or a sandwich, with some iced claret and water, or, in cases of feeble health, or where extra fatigue is undertaken, some stimulant in the shape of sherry or even brandy and soda-water, advisable. Of one thing, however, we are sure: that the frequent recourse to very small doses of alcohol in a variety of shapes is bad.

The Yucca as a Vegetable.—A plant of great interest is the *Mague* or *Mescal*, growing in Southern Arizona—a peculiar species of *Yucca* (probably *Y. brevifolia*). The plant consists of about eighty to one hundred leaves, from 2 to 3 feet long, pointed to a sharp thorn at the end; all the developed leaves are concentrically united at the ground; those undeveloped (the heart of the plant) remain soft and perfectly white so long at the sunlight is kept away by surrounding outer leaves. The Indians bake this heart in coals for eight or ten hours, when it acquires an exceedingly sweet taste, much like honey. The Mexicans also prepare from this baked *Mescal* an alcoholic beverage.

THE ARBORETUM.

BAMBOOS AND HALF-HARDY TREES AND SHRUBS
AT FOTA, CORK HARBOUR.

IN the beautifully laid-out pleasure grounds of this fine demesne, the *Benthamia fragifera* or Strawberry tree, which is also known by the name of *Cornus capitata*, indigenous to Simla and Bootan, attains a luxuriance and beauty unequalled in my experience in any other part of the kingdom; the finest specimen, now (July 10) completely covered with its large and showy white blossoms, is 24 feet in height and 123 feet in circumference, its branches trailing down to the ground, and the whole forming a most beautiful and conspicuous object in the grounds. There are a number of others scattered about the grounds, many of which reach the height of 40 feet, but are not such spreading or well-furnished specimens as the one above-mentioned. This ripens its handsome fruit in large quantities towards the end of August; it is, however, not allowed long to adorn the tree, as it is most greedily devoured by birds as soon as ever it ripens; they are attracted by its bright colours. The fruit is well and accurately figured in Vol. 78, of the *Botanical Magazine*, tab. 4,641. The next most striking and uncommon plant in this collection is the variety of Bamboo named *Arundinaria falcata*, with which a small island in a piece of artificial water is completely covered, producing, when the graceful feathery foliage is at its best, which it will be next month, a most beautiful and striking effect. The Bamboos grow in clumps of from 400 to 500 canes each, about 18 feet in circumference, and usually reach a height of from 24 to 26 feet. Underneath these Bamboos were planted, at the commencement of last autumn, two fine specimens of the fine tree Fern *Dicksonia antarctica*, which are looking at present in extremely vigorous health, having thrown up several new fronds at the commencement of this summer, and seeming not to have suffered in any way from the previous winter, which, however, was one of the mildest we have had in this district for many years. It is to be hoped that these tree Ferns may in time get quite acclimatised and reach a large size in this exceptionally sheltered and favoured situation. The ornamental water round the Bamboo island is now very gay with the bright golden blossoms of that pretty hardy aquatic, *Nuphar pumila*, which reproduces itself with the greatest possible rapidity from seed. The deliciously sweet-scented, and far too little grown *Aponogeton distachyon* has also been in profuse and almost continuous bloom for the last nine months, and has now lost all its leaves and apparently gone to rest for a season; it is perfectly hardy. The banks of the ornamental water are adorned with a profusion of the handsome *Phormium tenax*, or New Zealand Flax, which here attains the utmost luxuriance, many of the clumps being 13 feet in diameter and 9½ feet high, interspersed with huge tufts of the Pampas Grass (*Glycerium argenteum*), and, with Bamboos in the centre of the island, they impart to the place quite a tropical appearance. In another part of the grounds, *Chamærops humilis* has been planted out, without any protection, thirteen years, and is now 10 feet in height with a trunk 3 feet in circumference at the base. *Dracæna* (or as it is now more correctly named *Dracænopsis*) *australis*, has been planted out for over four years, and is now over 9 feet high. The Tulip tree (*Liriodendron tulipiferum*) is very fine

here, one specimen measuring rather over 60 feet in height and 11 feet in circumference of trunk at a distance of 4 feet from the ground; this tree blossoms freely nearly every year. There is also one of the finest specimens of *Pinus insignis* here that I have ever seen anywhere; it measures 168 feet round its branches, which feather beautifully down to the ground, and its trunk, at a distance of 1 foot from the ground, measures 10 feet in circumference. The *Eucalyptus globulus*, or Fever Gum tree, has here reached the height of 45 feet, and its trunk 2 feet from the ground measures 7 feet in circumference, but the timber is so extremely brittle, that every severe gale tears off from it several branches, thus detracting much from what would otherwise be a very fine specimen of this uncommon and valuable ornamental tree. The common *Arbutus* thrives exceedingly well here, and one fine specimen measures 150 feet round the outside spread of its branches. There are also some very handsome specimens of the *Cryptomeria japonica*, one of them measuring 35 feet in height, with a spread of branches of 95 feet in circumference. A fine specimen also

of the *Taxodium*, or *Sequoia sempervirens*, has reached 40 feet in height, and measures 8 feet in circumference of trunk at the base. The proprietor of these beautiful grounds is most anxious to increase the number of handsome plants, usually considered tender and requiring the protection of a greenhouse, but which live and thrive in the open air in this mild climate. He has, therefore, planted out with this view *Cycas revoluta*, and a number of other fine things, some of which it is hoped may ultimately prove hardy. W. E. G.

Abies Gordoni pumila.

GORDON'S DWARF FIR.

(ABIES GORDONI PUMILA.)

THIS variety, which was raised by M. Molet, nurseryman, of Plessis-Piquet, forms a dwarf pyramidal shrub, with numerous erect branches, covered with a smooth bark of a light green or slightly yellow colour. The leaves are of a deep green on the upper surface, and are marked underneath with two glaucous bands. It forms a very handsome miniature shrub, well suited for small lawns or gardens, while the leaves never turn brown under the sun, as those of the parent plant are liable to do. Another advantage which it possesses over the latter is, that cuttings from all the branches form vertical leading shoots as readily as if they were seedlings, a property which belongs to hardly any

other species or variety of *Abies*. The general appearance of this graceful variety is well shown in the accompanying illustration. W. M.

NEW METHOD OF CLEARING GROUND OF TREES.

WE had an opportunity of witnessing the other day, on the estate of Graugemuir, near Austruther, a new system for clearing ground of trees, recently introduced by Mr. A. Gilchrist, Carvennour. Mr. Gilchrist, as local manager in Fifeshire for the Scottish Steam Cultivation Company, has of course long been familiar with the use of agricultural engines, and when it became necessary, some three or four years ago, to root out an old hedge which encumbered his farm, he bethought him of attaching chains to the stumps and drawing them out by means of the steam drum commonly used for plough traction. Finding that a great deal of time and trouble was thus saved, he applied the same method to the removal of trees, and with results equally satisfactory. There is now, for example, lying on the farm the stump of a tree 3 feet in diameter, which he successfully uprooted. The system has since, we believe, been tried in various

places—among others on the property of Mr. Gordon, of Cluny, and on the northern estates of the Duke of Sutherland. As exhibited the other day, it was applied to the removal of a strip of plantation, consisting of Oak, Beech, and Plane trees, said to be about a hundred years old, but which have made no advance in growth for twenty years past. The engine, a machine of 12-horse power, being the same that is used for steam ploughing by the wire-rope system, was placed in an adjoining field, near the trees to be operated upon, though it subsequently appeared that the work could be done as effectually from a distance of 150 or 200 yards. A chain being hitched round a tree at such distance from the ground as might be deemed advisable, the wire rope of the engine was attached, when, with a turn or two of the drum, the roots were wrenched up bodily with a large ball of earth adhering. Notwithstanding that the soil was dry and hard, the work went on apace, about 300 trees, varying from 6 to 12 inches in diameter, being rooted up in a few hours. The machine was afterwards removed to the vicinity of another plantation, where considerably larger timber could be operated on. Here, on the first trial, a sturdy Beech of 22 inches in diameter was overturned without difficulty. A couple of Oaks of rather smaller girth were next dealt with, but in their case the roots held fast till the timber gave way under the strain. The same thing had happened with two or three of the smaller trees operated upon earlier in the day, the reason apparently being that, with a view to get the largest possible leverage upon the roots, the chains had been fixed too high. The experiments seemed to show that with a sufficient power, applied at the proper height, any tree of ordinary dimensions could be wrenched from its bed. It was equally evident, however, that for trees of large size, which required to be laid hold of at no great height, considerable engine-power and thoroughly reliable tackle would be necessary. The last tree taken in hand was a large Beech, similar to the one that had been successfully lifted. In the first instance, the chain was attached too high, and when the pull came the trunk was split. A fresh hold was then taken within a few feet of the ground, but the consequent loss of leverage involved an increase of strain, under which the wire rope gave way, though it was clear that if the tackle had held good the tree would have yielded to a little more pressure. Among those who witnessed the trials were Mr. James Whyte and Mr. Miller (of the firm of Messrs. James & John Miller), both of whom are specially interested in the system with reference to its applicability to Canada. It is estimated that with an engine specially constructed for the purpose, say of 14 horse-power, an acre of forest timber could be thoroughly uprooted in the course of a day's work, being as much as a man could cut down in a week, leaving the stumps and roots to be subsequently dealt with. In this view the matter has presented itself to the minds of some enterprising gentlemen as a promising commercial speculation, and we hear that a movement is on foot for the formation of a company, with the Duke of Manchester as chairman, with the view of putting the system into a practical shape. Besides the facilities it offers for clearing land intended to be cultivated, it seems to commend itself to those interested in the timber and bark trades; hence the attention bestowed on it by a firm like that of the Messrs. Miller, which uses annually in the manufacture of tanning the bark of many thousand Canadian Hemlocks.—*Scotsman*.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

New White Lilac.—Mille, Legraye, florist, of Liège, has succeeded in raising a new variety of White Lilac, which is described in the *Belgique Horticole* as being exceedingly fine, the flowers being of large size, good substance, and of the purest white colour, with anthers of a golden yellow, and arranged in large well-furnished clusters. The jury at the International Exhibition at Maestricht awarded the plant a first prize, and also bestowed on it the title of Reine des Pays-Bas (Queen of the Netherlands).

Reid's Weeping Peach.—This is decidedly pretty and attractive, for, in addition to its gracefully drooping branches, the bloom adds another interesting feature to the tree. It was a chance seedling that originated in the grounds of the late Mr. William Reid, of Elizabeth Town, New Jersey, and in its natural state was a sprawling shrub. Worked standard high, however, it becomes very graceful without artificial training.—*Horticulturist*.

Virginian Date Plum (*Diospyros virginiana*).—This handsome tree has always struck us as worthy of a place among those having a pendulous tendency though it can only be said to be so in a slight degree. The glossy dark green foliage and distinct aspect of this tree also recommend it greatly. The most accessible specimen we know of is in the Long Walk, Kensington Gardens, but it is not rare to see good ones wherever collections of trees have been planted.

Bog Yew.—This wood is to be found plentifully in Irish bogs, and some of it is so hard that it gives fire at the stroke of the hatchet. A variety of useful domestic utensils and furniture have been made from it. We have seen rolling-pins, punch-ladles, chests, tables, chairs, and various ornaments made from the bog Yew. The ordinary varieties of the Yew, foreign and acclimatised, are extensively used for furniture-making purposes, and the root of the tree is sawn into veneers, on account of its fine feathery vein, which shows well when polished. The wood is applicable to the making of mathematical instruments, comb, and pipe making, and several ornamental uses, through the skill of the turner and carver combined.

THE LIBRARY.

ROSES AND ROSE CULTURE.*

IN this little shilling book, consisting of eighty-three pages, Mr. William Paul tells amateur Rose growers all that is really necessary for them to know, in order to make them successful rosarians. The following chapter on the pot Rose will show the way in which the different subjects are treated:

In what manner shall we grow our pot Roses? This is the first point to settle. Shall we choose them on their own roots, or worked on the Manetti or Dog Rose? Shall we not also have a few standards as well as dwarfs in pots? I may briefly say that I prefer on their own roots such kinds as grow freely in that way, because they renew themselves continually and vigorously by suckers or underground shoots. But some kinds thrive better "worked," and, therefore, the sound rule of practice is to choose each variety in the way in which it is known to grow best. As to standard Roses, they are beautiful objects in pots for conservatories, especially the Moss and Tea-scented kinds, although they are scarcely suitable for small greenhouses. The spring or early summer is a good time at which to begin this branch of Rose-culture. It is the greatest economy to choose plants a little in advance of the ordinary sale plants. When such can be obtained, grow them under glass in a cold frame or greenhouse throughout the summer. It is important that the summer's growth should be well matured before the leaves fall, and an early growth should be encouraged. Such kinds as cannot be obtained in pots in spring and summer may be added from the ground in autumn (October), and, when potted, should be plunged in some sheltered situation out-of-doors. Assuming that pot Roses are required to flower in the month of May, before the Roses appear out-of-doors, the plants should be pruned and placed in a warm pit or greenhouse in February, slightly increasing the temperature from week to week, until a maximum of 60° by day and 50° by night be obtained. Syringing should be freely resorted to morning and evening in warm, sunny days, and sparingly applied in cold, cloudy weather. Clarified soot-water is highly valuable for this purpose. As the greenfly appears (which it surely will do), the house must be filled with tobacco-smoke from time to time. Mildew, should it arise, must be kept in check by dusting the leaves with sulphur immediately after syringing. Roses, when in pots, having but a limited area from which to draw their food, require a rich soil, and this should be supplemented from the time the leaves are half-grown until the flowering is over with constant doses of weak liquid manure. Roses in pots, when growing and flowering, can scarcely be over-watered, provided the pots be well drained and the soil thoroughly porous. Two parts good fibrous strong loam, two parts well-decayed stable-manure (the remains of a hot-bed), and one part drift or river-sand, will form a capital soil for them. Crushed bones in small quantity may be added, as they yield a permanent supply of food, and increase the porosity of the soil. Plants growing in pots should be pruned much closer than those growing in the ground. In fact, with the exception of the hybrid Bourbons, and some few shy-blooming hybrid Perpetuals, the pruned shoots should not be allowed to develop more than two eyes each. These should be obtained from near the base of the shoot, not quite at the base, for those lower eyes, if they develop, should be rubbed out. The dormant eyes will quickly burst forth after pruning, and should be closely watched, that the Rose-grub may be destroyed, or the flowering will be irregular and unsatisfactory. Supernumerary buds should also be rubbed out in this early stage of growth, especially if a moderate number of large handsome flowers is preferred to a larger number of small ones. As the shoots increase in length they should be tied out, each flower-shoot having a separate stick to support the flower. Just before the plants come into bloom, a thin shading of scrim should be drawn over or under the glass, to protect the flowers from the sun, and the temperature may be slightly lowered, to prolong the period of flowering. When the flowering is over, the Tea-scented Roses should be allowed to make their new or second growth under glass, but the other kinds may be removed out-of-doors to some spot sheltered from the full sun and wind, that the foliage may be preserved in a healthy and perfect state. The Tea-scented may be removed to join them when the growth is finished and partially hardened, and the whole may be taken back to the house about the end of September, re-potting at the time such as may require it. Although Roses in pots may be grown to flower finer in May than in any other month, they may be had very good in March and April. The same method of growth is followed for the earlier as for the later bloom, but the plants should be brought to rest at an earlier period and set growing early in January, a greater degree of heat being maintained if March and April Roses are sought

* "Roses and Rose Culture." By Wm. Paul, F.R.H.S. London: Kent and Co.

for. A span-roofed house sloping to the east and west is the most suitable for pot Roses. The plants should be kept as close to the glass as possible, and there should be the choice of giving either top or side air, or both, when required. It should be mentioned that some Roses produce finer flowers when grown in pots under glass than when in the open air, and different varieties are much influenced by the varying systems of cultivation. The groups of Roses best suited for growing in pots are Tea-scented, Hybrid Perpetual, Hybrid Bourbon, Noisette, and Bourbon, and to these should be added the Moss, on account of their picturesque beauty and distinctness. Certain kinds of Roses which grow and flower freely (the Chinese and Tea-scented especially) may be so managed as to produce flowers throughout the month of December. The plants which have flowered in May may be used for this purpose. It is only necessary to keep the successional flowers which arise in July and August suppressed in the bud state, when fresh shoots will push forth bearing flower-buds. Carefully preserve these by placing the plants in a tolerably dry and warm house by the end of September, and the flowers will expand slowly and at intervals up to Christmas. These plants cannot, however, be brought into flower early the next year; they must have their period of rest, and should be kept as backward as possible in the succeeding spring, so that they flower in June and July.

A TREATISE ON FOOD AND DIETETICS.*

This is a good book on a very important but much neglected subject. Even horticulturists, familiar with the rapid march of progress in our own art, have often little idea of the greater rapidity in the progress of the science of chemistry and other branches of knowledge which bear on the question of dietetics. The discoveries and experiments made within the last dozen years have completely upturned most of the previously received theories on this matter, and hence the necessity for treatises like this, which keep the student "up to the time" in the matters of which it treats. We are glad to observe that the author goes some way towards telling the truth about the exaggerated importance attached to meat as human food, and the evil results attending its excessive use; but, even he is a little hampered by popular use and prejudice in this way. No fact within human experience is more fully proved, than that perfect development of man, physically and mentally, is attained on food gathered from the vegetable kingdom exclusively, or with a very small proportion of meat. Let no one think that the discussion of this matter is without our province, for, it is beyond a doubt, that the erroneous estimate of the importance of an abundance of meat food at all meals (which is an article of faith with the Anglo-Saxon race everywhere), leads directly to the neglect of our fruits as articles of food, and of vegetables and their preparation for the table; and, thus it is that, whereas, we have meats in variety, and of the best quality, in good hotels and restaurants, vegetables as to kind, quality, or cooking, are, as a rule, so wretched, as to be incredible. The author says on this subject:

Thus it is seen that a great diversity exists as regards the food consumed by the human race in different parts of the globe. Instances are to be found where life is sustained upon a wholly vegetable, a wholly animal, and a mixed diet. The mixed diet, however, may be regarded as that which, in the plan of Nature, is designed for man's subsistence. It is upon this that he appears to attain the highest state of physical development and intellectual vigour. It is this which, certainly in temperate climes, he is led to consume by general inclination, when circumstances allow the inclination to guide him; and, lastly, it is this which stands in conformity with the construction of his teeth and the anatomy of his digestive apparatus in general. Notwithstanding these considerations there are those—but few in number, it is true—who contend that vegetable food alone is best adapted to meet our requirements. Under the style of vegetarians, they act upon the principle they profess. It is true that vegetable food, with its large proportion of non-nitrogenous matter, yields, in a simple and direct manner, according to the views now entertained and fully discussed in an earlier part of this work, the requisites for force as well as heat-production; and, in order to show that vegetable food is better adapted than animal for contributing to the performance of muscular work, reference has been made to our beasts of burden, which, as is well known, belong almost exclusively to the herbivorous tribe. That carnivorous animals, however, are not unsuited for such purpose is proved in the case of dogs, which, in some northern and other countries, are very extensively employed

for the performance of work. To regard man's maintenance too closely in association with the mere performance of mechanical work—to look upon him, in other words, as though he were solely designed for the conversion of food into mechanical power is not, it may be also said, taking a high view of his position. The prevailing tendency, certainly in the England of the present day, is to give an undue weight to the value of animal food, and this has been encouraged by the teachings of Liebig regarding the origin of muscular power—teachings which, during the last few years, have been shown to be untenable. Many people seem to look upon meat almost as though it formed the only food that really nourished and supplied what is wanted for work. The physician is constantly coming across an expression of this view. Undoubtedly a greater feeling of satiety is produced by meat than by other food. It forms a greater stay to the stomach, but this arises from the stomach constituting the seat of its digestion, and a longer time being occupied before it passes on and leaves the organ in an empty condition. Against those who think that a large consumption of meat is a *sine qua non* for the maintenance of health and strength, the experience of vegetarians may be adduced. In the effects of the Scotch prison dietaries, corroborative testimony is afforded. Dr. J. B. Thomson, for instance, resident surgeon to the General Prison for Scotland, writing in the *Medical Times and Gazette*, Vol. L, 1868, speaks in favour, from ten years' experience, of a diet into which meat entered very sparingly, and which contained instead a moderate amount of milk. He says, since the employment of the improved dietaries sanctioned by the Secretary of State in 1854, the dietary in the General Prison for Scotland for all adult male prisoners, under sentence of nine, and not exceeding twenty-four months, had consisted of bread, oatmeal, barley, 1 oz. of meat per diem, made into soup, with succulent vegetables, and 20 oz. of skimmed or butter milk. One day in the week fish had been substituted for the soup. The health of the prisoners had been uniformly good. Weighing on admission and liberation had been carried out, and 88 per cent. were found to have gained or maintained their weight. Again, as shown by one of Dr. E. Smith's reports, it is not uncommon to find, amongst the agricultural labourers of Scotland, that no meat is consumed, oatmeal and milk forming their staple articles of diet. Further, Dr. Guy, from his observations in the case of English prisons, gives as one of his deductions, "that we possess conclusive evidence of the sufficiency of a diet from which meat is wholly excluded, and even of a diet consisting wholly of vegetable matter."

I have introduced these particulars, not for the purpose of showing that a diet without meat is to be considered desirable, but for strengthening the argument that the consumption of meat to the extent that many persons believe necessary for the maintenance of health and strength is not in reality so. It has been before stated that physiological considerations point to a mixed diet as being most in harmony with our nature, and it may probably be considered that the most suitable admixture contains about one fourth, or rather more, of animal food. With more animal food than this, the excretory organs are unnecessarily taxed, and the system exposed to contamination with impurities, for the nitrogen of the superfluous nitrogenous matter has to be eliminated, and is found to escape, in combination with other elements, under the form of certain excretory products, without having contributed to any useful purpose. A defective transformative and eliminative action will lead to a retention of the products of metamorphosis of this superfluous nitrogenous matter in the system, and there is reason to believe that gouty affections, and other morbid conditions, are sometimes induced in this way.

To Soften Hard Putty.—It is well known that common putty becomes exceedingly hard with age, a circumstance which renders the removal of glass from sashes peculiarly difficult. A practical man tells us that he thinks himself lucky if he can take out one pane out of three without breakage. It is stated, however, that the putty may be softened by using a paste of caustic potassa, easily prepared by mixing the caustic alkali, or even carbonate of potash or soda, with equal parts of freshly burnt quick-lime, which has previously been sprinkled with water, so as to cause it to fall into powder. This is then mixed with water to a paste, and is spread on the putty to be softened. Where one application is not sufficient, it is repeated. In order to prevent the paste from drying too quickly, it is well to mix it with less water, adding some soft-soap instead.

Digging, a Cure for Dyspepsia.—A gentleman saw an advertisement that a receipt for the cure of dyspepsia might be had by sending two postage stamps to the advertiser, and the answer was, "Dig in your garden, and let whisky alone."

THE GARDENS OF ENGLAND.

THE ROYAL GARDENS AT HAMPTON COURT.

HAMPTON COURT GARDENS are beautiful in spite of their geometry. They are a fine example in every line (shown below, as it was originally) of the old geometrical style of gardening. But, while they are, and we trust will long remain, an example of the school universally adopted before the natural idea of landscape-gardening began to take root, it is well to bear in mind that the old plan of torturing the trees into fanciful and unnatural shapes has been abandoned. Hence we have avenues of Limes glorious to see; had the antiquated *hâtuise* of mowing them into walls, as now practised round Paris, been carried on at Hampton Court, we should have had little more to see than in any of those

that carelessly sprung from the base of the old terrace wall, than in any of the more carefully cultured bedding plants; and herewith furnish an engraving of a sketch, taken on the spot, of the Solomon's Seal (*Polygonatum multiflorum*), one of the most graceful of plants, and which should have a place in every garden. We had been accustomed to regard it as most fitting to adorn quiet shady walks and wild places; but here it is on the full glare of the terrace, just as lovely in effect as it would be anywhere else.

The annexed isometrical view of the Palace and Gardens of Hampton Court conveys a very complete idea of the laying-out of the place. There is, however, among many advantages, one disadvantage, in the isometrical system, as illustrating a general plan, which is, that full-grown trees, especially in a plan consisting of intricate parts, must necessarily be dwarfed in order not to confuse the perspective lines; and, therefore,

Hampton Court Gardens.

supremely dismal French gardens, such as that of Sceaux and many others, where the heavy walls of clipped Lime trees, hideous in themselves, steal every grace from the garden. Even the old Yew trees, allowed to free themselves from their old clipped form, and send their plummy branches forth naturally, are a great advance on the clipped tree of any kind, though they are so numerous at Hampton Court as to produce a somewhat monotonous effect. In those dreadful old shearing and clipping days, we believe they did not clip the flowers. Had they the modern flower-garden notion of pinching and clipping *Cerastium*, *Santolina*, &c., &c., into neat little hedges, it would have greatly increased their resources for formalism. On a recent visit to Hampton—now like all the great gardens round London, extensively adorned with “bedding plants,” very well done according to the standard in such matters—we found, as we thought, more beauty in an old English flower

the gardenesque beauty of the place is, necessarily, not done justice to. The great churchman and minister, Cardinal Wolsey, in selecting this spot for the erection of a palace, maintained the credit of his cloth by the choice of such a site. Our wealthy and powerful ecclesiastics have, ever since the firm establishment of Christianity, shown acuteness and good taste in the selection of some of the most lovely vales of fair England for the erection of their monasteries and episcopal residences, choosing, with taste and judgment, situations in which soft green slopes, a running stream, and noble woods, combined to give both beauty and value to their dwelling. The river gave them fish; the forest, game; the southern slopes of their open land furnished ground for their luxurious gardens as well as rich pastures for their cattle. Wolsey, one of the last of the race of those opulent Churchmen, erected one of the last of the great ecclesiastical residences at Hampton, not long before the Reformation. Shortly before the whole-

sale confiscations of the time, the noble riverside palace of the Cardinal had already fallen to the share of the king himself, and has ever since remained a royal palace, though not regularly inhabited by the royal family since the time of William III. It has been said that the portion of the gardens, known as the wilderness, is not in harmony with the rest of the laying-out—that may be so—but it is yet very interesting from an historical point of view, as being a remaining part of the original plan of the Wolsey gardens. It was, in the Cardinal's time, quite customary to retain a part of the pleasure grounds in a state of nature; and such had, indeed, been the custom in baronial and royal, as well as ecclesiastical, gardens, from a very early period. In fact, nothing between an absolute wilderness, and a formal geometrical garden was then understood; for landscape gardening is a modern art. Our ancestors knew nothing of that gentle subjection of nature to somewhat smoother and more regular forms, freed from too much

out the enlargements of the palace in the Romano-Italian style of the day. The eastern terrace at Hampton Court is a noble walk, and perhaps the finest thing of the kind in Europe, the views from which, down the two diverging glades, are extremely pleasing. The isometrical plan, as has been said, conveys no idea of the effects of full-grown foliage trees, some of which are remarkably fine, especially a very noble Catalpa; but, as showing very accurately the mode of laying-out, the system is perhaps more useful, in some respects, than a picturesque one, which, however, it is intended to give on some future occasion. On the accession of William III., important alterations and additions were made, in which, of course, the Dutch style predominated, but it did not harmonise badly with those of the reign of Charles II. The Dutch King went in very largely for cropping and shaping; and there appeared, under the persevering efforts of topiarian skill, tree lions, tree elephants, tree peacocks, tree bears, and tree statuary—all shaven and shorn, into their

Solomon's Seal on the terrace at Hampton Court.

ruggedness and too much weediness, without making it formal. But the innate love of Nature was still there, as evidenced by the preservation of a portion of land, in a wild state, near the residence, so as to be conveniently accessible at all seasons; and where la belle Chatelaine, or my Lady Abbess could roam freely in coming spring, and watch, day by day, the first peeping of the Snowdrops through the winter-bronzed turf. In remote places, there is still many an old mansion, with the ancient appendage of a "wilderness;" though by far too many have been lopped and trimmed, and smoothed out of existence by modernising gardeners; and so, the wilderness of Wolsey, at Hampton Court, is at all events, an interesting relic of our old national style of romantic gardening, or rather of *leaving alone* a certain portion of the pleasure-grounds.

The semi-circular flower garden, spreading from the terrace of the eastern front, was planned in the reign of Charles II., probably at the same time that Sir Christopher Wren carried

respective forms, out of Yew, Rosemary, or Box. These innocent wild creatures were the delight of the King, who was a topiartist *par-sensu*, and was never tired of watching their forced growth into the desired shapes. Many of the devices remained, and were well kept up as late as Horace Walpole's time, who greatly admired their ingenuity, and has placed his *flit* of approval on record. It is almost to be regretted that some remains of the Yew-tree bears do not remain at the present day—even at the risk of ill-naturedly caustic critics calling the place a "bear-garden." H. N. H.

A Noble Effort.—We understand, from a contemporary, that "the Royal Horticultural Society are entering into an arrangement with Messrs. Prince for establishing in the Royal Horticultural Society's Gardens at South Kensington a skating rink; it is confidently expected that this important addition to the attractions of the gardens will lead to a very considerable increase of the Society's funds."

THE FLOWER GARDEN.

SAXIFRAGES.

By J. C. NIVEN, Botanic Gardens, Hull.

The Opposite-leaved Group.

So remote in outward appearance are the representatives of this section to those of the preceding, that, in the absence of the flowers, it would be utterly impossible to recognise the relationship—the former with largely-developed leathery leaves, some 8 or 10 inches long, the latter with an altitude only to be measured by the decimal parts of an inch. Yet it is questionable if there can exist a more lovely and loveable plant than *Saxifraga oppositifolia*. The sectional title applied to this group by Tauchnitz, viz., *Porphyrium*, is perhaps as happy a one as ever was given to a plant embodying, as it does, the appellation used by the ancient Greeks for the purple or Tyrian dye. No one who has seen this Saxifrage in its Alpine habitat, with the vivid purple robe of Nature still impressed on the eye, as it must have been, but will at once acknowledge the correctness of the nomenclature, especially if it has been their good fortune to fall in, as I once did, with the major or larger variety. No words can express its beauty, no painter could commit to canvas the impression conveyed by viewing a large extent of heatherland suffused by the rich tint of this early spring Saxifrage. Long before the denizens of the heath have awakened into vital activity our purple mountain Saxifrages have paid their votive offerings at Flora's shrine, possibly the very first at their high altitude that have been presented, and, consequently, all the more acceptable.

S. oppositifolia of Linnaeus forms extensive patches of slender procumbent, many branching stems; the leaves, as may be inferred from the name, are opposite, broadly ovate, fleshy, obtuse at the point, and slightly reflexed, with a single pore or hole inserted in the flattened extremity; the margins are ciliated with bristly hairs, somewhat deflexed downward, they form an exceedingly pretty object under a moderately powerful glass, each little branchlet simulating very perfectly an obtuse leaved Aloe; the flowers are solitary on short peduncles, about the size of a three-penny piece, and, as before stated, of a rich purplish-crimson colour; the petals are obovate, slightly unguiculate, and five-nerved. This charming Saxifrage appears to possess a world-wide geographical range, at least, throughout the northern hemisphere, from the Sierra Nevada to Spitzbergen, on nearly every mountain height; eastward through Siberia, even to Thibet, and westward through Greenland and Labrador, as far as Unalashka, it has no equal in this respect amongst all the Saxifrages.

S. oppositifolia var. *grandiflora* of Engler is more familiarly known in this country as the major variety, it has broader and more densely arranged foliage, its flowers have obovate petals, distinctly unguiculate and seven-nerved, they are fully double the size of the normal type, and possess a richer and deeper colour as well. This form, said by Engler to be Pyrenean, is also met with in Britain, though but rare.

S. oppositifolia var. *alba*, though not mentioned by Engler, has been for many years in cultivation in this country, besides being at once distinguished by its pure white flowers, it has a markedly slender growth as compared with the others; owing to the leaves being further apart the dark red colour of the tiny stems is rendered conspicuous; so distinct is the plant that, in the absence of the flowers, it may readily be picked out from among any number of the other varieties. What its origin is I know not, I have never met with it wild, nevertheless, it is quite possible it may be a casual sport picked up on some of our British mountains.

S. oppositifolia var. *pyrenaica* has a good deal the appearance of an intermediate form between *oppositifolia* and *biflora*; its leaves are far less fleshy than those of the former, larger, more densely ciliated, and not abruptly shortened at the point; the flowers are of a pale rosy tint, hence it not unfrequently goes by the name of pallida. It is often mistaken for *biflora*, but, unlike that species, is essentially an early spring bloomer.

S. oppositifolia var. *Rudolphiana* of Hornschuck, is the most diminutive of all this section; the stems are densely abbreviated and covered with small leaves. I believe it is in cultivation with Mr. Maw, but I have not heard whether it has yet bloomed.

S. biflora of Allioni, is synonymous with *S. rosea* of Lapeyrouse, and was supposed by Willdenow to be but a form of *oppositifolia*. It is, however, a perfectly distinct plant, its general growth is stronger, the leaves larger, and further apart, not fleshy nor smooth, but pilose, or more correctly described as downy, especially on the

upper surface; the procumbent stems also are hairy, and altogether more lax in growth than any of the forms of the previous species. The flowers are produced from two to seven in number, in a sort of lax corymb, of a size about equal to that of the large flowered variety of *oppositifolia*, and of a deep rosy tint; its time of blooming is July and August, but this lateness may, to a great extent, be accounted for by the great altitude at which it grows, rendering it late in the spring, or even early in the summer ere it gets relieved of its winter's snow covering. Possibly to this very fact we must attribute the great difficulty which we find in its cultivation. With every chance of success, last autumn, offered by a supply of nice patches, just brought home by Mr. Maw from the Piedmont Alps, and planted in various situations, my only report is, that they are all dead. Since writing these descriptive articles, I have had a large correspondence with Saxifrage growers, and in every instance where *S. biflora* was reported as growing freely, it turned out to be only the pyrenean form of *oppositifolia*. I will not, however, yet despair. I got a few pods of ripe seeds from the plants last autumn, and, from a spring sowing, there are at present half a dozen or more tiny plants, which may yet yield the elements of success; perhaps some of my readers may be able to throw some light on the subject. Our plant is a native of the Pyrenees and the Maritime Alps.

S. macropetala of Kerner is the name adopted by Engler for what we cultivate as *S. Kochii* of Hornung; or, perhaps, I should say, ought to cultivate, as I have very grave doubts as to whether the true plant is in cultivation. Those plants that I have had under that name from three different sources, have proved untrue; at least, they do not answer Engler's description in the matter of foliage and habit; neither of them have yet flowered, so, perhaps, I ought not to condemn them in too positive terms. The leaves of the true plant have a more dense arrangement than in *biflora*, the flowers are produced in corymbose clusters, varying from two to five in number, the stalks covered with glandular hairs, as also are the calycine divisions. Kerner's plant is said to be a native of the mountains of Switzerland, Carinthia, and the Tyrol.

S. retusa of Gouan, is known under the following synonyms—*S. imbricata*, *S. Wulfeniana*, and *S. scorbiculata*; but of all these, decidedly the most appropriate, is that of Gouan, which has been in use for many years. Considerably smaller, more compact in growth, and harder to the touch, than any of the preceding species in this section, it is readily recognised. The leaves are thick and fleshy, almost triquetrous, retuse at the point, and supplied with three distinct pores, or dots on the upper surface; quite devoid of hairs or cilia, except at the base of the short petiole. Its flowers are produced sparingly, they are arranged in dense little groups of from three to five on a perfectly erect peduncle, about an inch in height, and present the appearance of a little group of intensely bright crimson stars; though, far from being as showy a plant as the forms of *oppositifolia*, it, nevertheless, possesses a charm of its own, and were it only a more abundant bloomer, it would become a formidable rival. It is a slow grower, but possesses a good vigorous constitution, and is equally hardy with the others, but requires a locality in the rockery, where thorough drainage can be had, and also, full exposure to the sun; the texture of the soil should be rendered free and open by an admixture of small nodules of granulated limestone, amongst which its little wiry roots delight to revel. It is most impatient of watering overhead, when succeeded by a bright sunshine. Two-thirds of a fine panful of this plant has become withered and brown in the course of a few days after this operation, which, is one to be avoided at any time, but especially is it the case with this plant. Its geographical range appears to be very similar to that of *biflora*, except that it extends farther eastward on the European Alps.

THE NEW GLADIOLUSES OF 1874.

M. SOUCHET, the successful raiser of many of the finest hybrid Gladioli, has been compelled through failing health to relinquish his favourite business; and henceforward the task of upholding the fame of the establishment will devolve upon his successors, Messrs. Souillard & Brunelet, whose novelties this season are eighteen in number, all of which are first rate. From these we select the following:—

Amalthee, a fine variety of moderate stature bearing a splendid spike of large, pure white flowers with broad patches of a rich violet-red; throat, violet velvety; anterior divisions of the perianth, slightly shaded with lilac.

Belladonna, a fine spike of well set white flowers shaded with bright lilac, the lower division marked with slender bright carmine stripes. Shape of the flower very peculiar and quite new.

L'Unique Violet.—Spike, very long, bearing unusually large dark lilac flowers tinged with violet, and flamed with deep carmine. A vigorous grower and of perfect habit.

Variabilis.—Spike, long, flowers extra large, pure white, spotted or not, and sometimes dashed with lilac; bottom of the throat violet. An exceedingly effective branching variety.

Merveille.—Very beautiful rose-cerise, faintly shaded with violet bordered and flamed with deep carmine; centre, very bright.

Psyche.—A magnificent large spike of delicate rose-coloured glazed velvety flowers, the inner divisions of a deeper rose, flamed with bright carmine. Unrivalled in form and colouring.

Arethuse.—A fine spike of perfectly formed delicate white flowers, faintly tinged with pink and striped and flamed with bright carmine.

Murillo.—A magnificent spike, bearing beautiful bright cerise-red flowers of extra size, all the divisions banded with pure white, and the lower ones almost altogether white. A first-rate variety.

Le Vesuve.—An extremely long spike of beautiful brilliant fiery-red flowers, very large and effective. A late strong-growing variety.

De Mirbel.—A large spike of extra large perfectly shaped widely-expanded handsome rose-coloured flowers, slightly tinged with violet or lilac, ground very bright, striped and flamed with deep carmine.

Asmodee.—A very beautiful spike of cerise-red or bright purple flowers, bordered and flamed with a rich garnet-red, spot and very broad rays, white. A very distinct variety.

Le Tintoret.—A very long and handsome spike of fine open flowers of a beautiful cerise, flamed with carmine near the edges, and with a carmine spot upon a yellowish ground. A strong-growing variety.

To the foregoing dozen unrivalled varieties, we may add the following six, which are scarcely inferior in point of form and colour.

Ondine.—A long spike of perfectly disposed white flowers shaded with lilac, each division furnished with a small deep violet blotch, and faintly dashed with very bright carmine near the edges.

Albion.—A very large spike bearing handsome white flowers of unusual size, faintly and delicately tinged with lilac and sometimes flamed with lilac-carmine. An extra tall variety.

Triumphans.—A very large and beautiful spike of cerise flowers, admirably set.

Cassini.—Extra large spike of perfectly arranged beautiful rose flowers flamed with carmine, lower divisions elegantly striped with carmine on a very bright ground.

Ambrose Verschaffelt.—A splendid spike of perfectly formed pink and white flowers, flamed with garnet-red, divisions with a large rose spot. An exceedingly effective variety.

Sirene.—Delicate clear bright rose, slightly tinged with orange and broadly rayed with red on the lower divisions, spot red on a yellow ground.—*Illustration Horticole.*

The Distribution of Alpine Plants.—M. De Candolle, at the recent Congress at Florence, explained that the pre-glacial Alpine flora was not able to exert a great influence on the existing flora, inasmuch as the great changes which took place during the glacial period had necessarily swept away this ancient vegetation. He could not agree with those who considered the Alps as a centre of diffusion of a special flora, but believed them rather to be the refuge ground for the plants, which, as the glaciers retired, had found conditions more favourable to their existence than in places lower down. In proof of this, he observed that the richest parts of the Alps for rare plants are those which were soonest deprived of glaciers, the ground having been thus cleared for the introduction of a more ancient flora, of which these rare plants are remnants. The southern, the eastern, and the western slopes of the Alps were successively cleared of the principal glaciers, and the Swiss Alps received their flora first from the south, and then from the east and west. M. de Candolle then asks, "Why should the plants ascend as the glaciers retreat, and why should there be greater variety in this advancing vegetation?" In pre-glacial times there was more moisture in the climate of Europe, and, consequently, the flora was richer and more varied. After a time, the climate became dryer, and, as the glaciers retired, many plants were able to maintain themselves, by advancing gradually over the ground as it became unoccupied by glaciers, finding there conditions more favourable for their growth. Hence one can deduce the law that the richness and variety of Alpine floras depend on the antiquity of their introduction. Mr. Ball approved of M. De Candolle's theory to a certain extent, but he did not consider it sufficient to explain all the facts. When, for instance, a rare species is to be found in more than one locality, it is natural to suppose that formerly it had occupied all the intermediate ground, and that the glacier coming through the midst of it had divided it into two groups. He was also unable to understand

how M. De Candolle's theory could explain the fact of certain plants growing vigorously in limited spots without extending their area, and was inclined to attribute this limitation to the nature of the rock, its chemical properties, &c.—serpentine, for instance, almost always supports a peculiar vegetation; thus the Engadine Valley, which must have very recently been freed from glaciers, is remarkably rich in rare plants.

Grass Walks.—To these there are a few drawbacks. It is said of Grass walks, "They are always green and pleasant to the feet, never wet, and much less troublesome than gravel walks." With respect to the appearance, I think a well-kept gravel walk does not look worse than a Grass walk, but, on the contrary, helps, by means of contrast with the green lawn, to make a garden look much more pleasant than it otherwise would do. It may be, that a gravel walk gives, in the beginning, a little more trouble than Grass, but, if well constructed, the trouble will be afterwards, if not less, at least not more than with Grass walks. I really never did see a well-constructed gravel walk muddy. One cannot enjoy a garden with Grass walks on a fine morning without getting wet feet, the Grass being damp with dew, neither is it possible to walk over Grass after a refreshing rain from the same cause, and thus one is deprived of the enjoyment of one's garden just when it is most desirable to take a walk in it. On the contrary, well-constructed gravel walks are always dry and pleasant to the feet, and I am sure, as I have said, will not give more trouble than Grass walks, which, if not mown very often, will become quite impassable, and serve as a retreat for snails and other insects.—G. WERMIG.

Plants Suitable for Draping Trees.—The common red-berried Bryony (*Bryonia dioica*) would make a suitable plant with which to drape trees. It is a graceful climber, and, as it does not ripen its fruit until autumn, its beauty would last for a considerable period. It is found in most parts of Europe, but, although common in England, in Scotland it is considered rare. Its favorite habitat is a hedge or thicket. I met with it last month in a shady Hampshire lane, one of those charming spots where the Hazel and Beech-clad banks, rising high on both sides, form a complete arbour. The Bryony was in full bloom, and its slender stems, numerous tendrils, large alternate Vine-like leaves, and delicate creamy-white flowers, beautifully marked with green veins, formed a very pretty picture. Draped round one of those old trees, to be found occasionally on lawns which are not of modern date, it would, I am certain, be a "thing of beauty," when its green berries had become red or bright orange, though not "a joy for ever." I am very partial to berries for winter decoration, although some of my special favourites bear rather a suspicious character, to which the Bryony itself is not an exception, for most authorities are of opinion that the fruit partakes of the poisonous properties of the root. There is another plant, somewhat similar to that just named, called Black Bryony, but which, in reality, is not a Bryony at all, but the common *Tamus* (*T. communis*)—also, a red-berried plant, which has long twining stems and a black root. The roots of *Bryonia dioica* are white, and were, in former times, believed by the Welsh, the lower classes at least, to be real "Mandrakes;" for herbalists used to obtain a very fair resemblance to the human figure from the roots of a thriving young Bryony plant by opening the earth round it, and placing the roots in a small plaster mould. They then carefully replaced the soil, and, by the end of the summer, accomplished their task, for the roots grow quickly, and, in most instances, assumed the form of the mould.—W., *Berry Grove, Liss, Hants.*

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Campanula Smithi.—You say (p. 62) that this is a hybrid between *C. Hostii* and *C. pulica*; it should have been between *C. fragilis* and *C. pumila alba*.—WILLIAM SMITH, *Wilmot Road, Leyton.*

Why Not?—Parsley properly belongs to the vegetable garden, but it makes a beautiful edging for flower beds, the bright green of its finely curled leaves giving a pretty finish to flowers that lack foliage. I am bold enough to use it thus and find it very effective.—R. N.

Madaria elegans.—Among the numerous members of the Composite order introduced into our garden, this hardy Californian annual deserves, I think, a word of commendation. It grows 1 or 2 feet in height, and bears narrow entire downy leaves, and lax-terminal cymes of showy pale yellow flowers nearly 2 inches in diameter. The ray florets are deeply three-lobed at the apex, and marked at the base with a red-brown spot. It is a plant that flowers well in the shade.—R. C.

The Best British Ferns.—Would you be good enough to give me a list of names of a dozen of the rarest and best British Ferns, such as would win in a good exhibition of them?—CRISPUM. [*Athyrium filix femina* Victoria, *Athyrium filix femina plumosum*, *Scelopendrium vulgare crispum letum*, *Scelopendrium vulgare digitatum*, *Adiantum Capillus Veneris*, *Allosorus crispus*, *Lastrea filix mas cristata*, *Lastrea dilatata cristata* Wollastonii, *Osmunda regalis*, *Polypodium vulgare cambicum*, *Polystichum angulare*, *Polystichum angulare Jonesii*, *Trichomanes radicans*, *Asplenium marinum*, *Polypodium Dryopteris*. The above are very beautiful when well grown, and are often met with at exhibitions. They are all British, and hardy.]

THE KITCHEN GARDEN.

COTTAGER'S KALE.

FROM the time that has elapsed since this vegetable was first brought under public notice, one might have supposed that it would have been more generally cultivated than it is. When first offered it received a very high character, not only for free growth, great weight of crop from the ground occupied, hardiness, enabling it to withstand the severest winters, but, above all, for its fine flavour. This high character has been fully borne out, and still we find numbers of gardens, in which this, the best Kale in existence, is not grown, and the place in which it should be found occupied by Scotch Kales, which are much inferior to it in flavour, and not superior in their power to withstand severe frost. The first season in which it was "let out" I grew it; but at the time of planting I noticed that there was a considerable difference in the plants, some being green in the stems, like ordinary Kale, others having more or less a purplish tinge. I at once concluded that the seed had not been carefully saved—that is, the seed plants had been, when in flower, growing too near some other of the Brassica family in bloom. Subsequent experience proved that in this I was mistaken. In planting, the green plants were put on a separate plot from the purple ones, but were treated in every way in a similar manner. In any plant essentially of a decorative character, novelty of some distinctive kind is a sufficient warrant for its cultivation. Not so with a culinary vegetable, the legitimate use of which is to be eaten. Consequently, I submitted this Kale to the test to which, with me, new vegetables are always subjected, viz., comparison when cooked with the best established variety that admits of being tested with the new comer. On this occasion, late in the autumn, I had Brussels Sprouts, Walcheren Broccoli, and the purple and green varieties of the Kale, cooked separately; also the two forms of the Kale cooked together. The verdict of myself and several friends was, that the green form was very much inferior to the Brussels Sprouts both in flavour and texture, being tough and stringy, and that when cooked with the purple completely destroyed the flavour of the latter, as well as gave the whole a disagreeably strong character. This mixture of the purple and green forms has doubtless had the effect of depreciating the value of this vegetable, for the purple, when cooked separately, was as different as could be, being as tender as Spinach, with a flavour more like that of Walcheren Broccoli than the Sprouts; the latter only surpassing it in appearance. From that time I have always grown this Kale as a crop to succeed Brussels Sprouts, giving up the Scotch Kales altogether, except a dwarf variety that is the latest of all in running to flower, and which bridges over the time from the end of the winter Greens until the first early Cabbage comes in. From the impression I had first formed respecting the seed plants being improperly managed, I determined to save my own, selecting nothing but purple-stemmed plants; kept them completely away from any other of the Brassica family, and, when in bloom, carefully covered them with hexagon netting, that effectually excluded bees and flies, yet the seed from these purple plants so treated produced as many green plants as of the colour wanted. The practice I have followed from that time has been simply in planting to reject all green plants, only using such as had the unmistakable purple tinge in the stems. To secure a full heavy crop it is not necessary to sow the seed as early as in the case of Brussels Sprouts, yet it should be in the ground by the middle of April. The land should be well prepared by a good dressing of manure, dug in not too deeply, for this, like all others of the Cabbage tribe, is a surface rooter; and, although all the family prefer a heavy, strong soil, still it should always be well pulverised so that the roots can extend in all directions without the obstruction of big, hard, unbroken lumps, that alike offer resistance and afford little nutriment to the tender feeding rootlets. An opinion sometimes exists, that in the preparation of ground for culinary vegetables, if a sufficient quantity of manure is dug into the soil within the distance that the roots of the intended crop will extend, this is all that is required. Such is by no means the case. The limited season that most culinary vegetables have in which to arrive at maturity necessitates the whole of their manurial food being evenly dispersed through the soil in which their roots extend; so that, from the day the young plant appears above ground until it is fit for the cook, it may have had all along a continuous supply of the necessary food. This cannot happen unless the manure is evenly dispersed through the soil, which is an impossibility unless, in digging, the ground is broken sufficiently fine, so as to admit of the equal dispersion of the manure. This, as will be obvious, is of less importance in the case of any plant that requires years to come to maturity. If space can be spared, the plants may be at once put out from the seed-bed, when large enough to handle, or they may be pricked out about 9 inches asunder, until some other crop is cleared

off to make way for them. A few words respecting this preparatory process may not be out of place. The freest-rooting plants in existence have need of all the roots they make; consequently, in transplanting even so common a vegetable as a Cabbage, it is essential to preserve as many of the roots free from mutilation as possible; yet, how often are these and other plants treated as if their roots were of little or no importance! As regularly as the seasons come round there is the recurring lament over Lettuce prematurely running to seed; Celery and similar things bolting. Can it be wondered at when, in taking up for re-planting, they are simply dragged out of the ground like weeds, three-fourths of their roots being ruthlessly torn off? Of the bad results arising from this barbarous work it is difficult to speak too forcibly. The necessity of using a trowel when planting, or of loosening the plants with a fork, so as to retain all the roots possible, may be insisted on, and yet not be always carried out by one's workmen. If anyone is doubtful as to the effect it has upon the crop ultimately, he may be convinced by simply noting the difference there will be all through the after-growth of any given crop, a portion of which is removed with all their roots intact, as compared with another portion torn up weed fashion. In preparing a nursery bed for this Kale, and all its congeners, the surface on which the soil is placed should be composed of as hard a material as can be got, so that the roots of the plants cannot penetrate into it; and the 6 or 8 inch of soil placed thereon, in which they are pricked out, should be thoroughly pulverised before the plants are put in, so that when removed they will come away with nearly all their roots entire. The plants in the nursery bed should never be over-crowded—9 inch each way is a good distance; when they are well cared for, and assisted with water when they require it, good crops can be obtained, even when they are removed to their ultimate destination in the garden—later in the season by some weeks than would be of any use in attempting with badly prepared plants—this is an advantage, more especially where space is limited. Cottager's Kale, like all other vegetables intended to stand the winter, should not be planted too thickly; the weakening influences of over-crowding show themselves, and render plants unable to resist an amount of cold that they would have withstood without injury, if they had had room sufficient for light and air to give them their wonted strength. If the plants are put out in the quarters where they are to remain, as early in the spring as they are large enough to handle, they should be planted 2 feet asunder in the rows, and the rows should be 2 feet 6 inches apart; if planted later in the season from the nursery bed, 2 feet each way will be sufficient.

T. BAINES.

Sea-weed and Sea-sand in the Culture of Seakale.

—Permit me to suggest that those of your readers residing near the sea-shore, who cultivate Seakale, should make use of both sea-sand and sea-weed if they desire to obtain really fine, yet delicately-flavoured crops. The name *Crambe maritima* points to the natural habitat of the plant, which is found in a wild state on different parts of the coast, growing upon shingle and sand. It was this which gave me the idea, now many years ago, of making use of sea-weed mixed with manure in the formation of Seakale beds, and of covering up with sea-sand such plants as I did not want to force, but cut from naturally. My Seakale, thus treated, was excellent, the Kale growing up through the sand being white, crisp, and free from any rank taste or smell. I planted a row of crowns in a bed formed of manure, sea-weed, and mould; and then in autumn, instead of covering with pots, I had a ridge of fresh sea-sand, nearly 2 feet in height, raised over the entire row. The Kale, thus treated, came in just as the forced row of plants was going out; directly the shoots began to peep through the top of the ridge, we removed the sand, and cut, from the crown, shoots very superior, in point of taste, to those of the manure-forced vegetable.—W., *Berry Grove, Liss.*

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

The Best White Cos Lettuce.—What is the best hardy white Cos Lettuce? —B. M., *Enfield.* [The best hardy white Cos Lettuce is Myatt's variety of the Covent Garden White Cos.—R. GILBERT, *Burghley.*]

A story is told of a citizen of Boston, U.S., who let a piece of ground to a man "on shares." The man wished to hire the lot, but the owner, doubtful of getting any money of the tenant, proposed to let it upon the promise of receiving half the products. Occasionally during the summer he passed the spot, and was pleased with the cultivation it was receiving, and with its goodly show of vegetables. Harvest time came and passed, and he heard nothing from his tenant till, in response to a hint, the latter sent him one Water-Melon and three shrivelled Cucumbers. Indignant at this treatment he called upon the man, and asked him what it meant. "Why, you see, squire," replied the tenant, "the boys stole all of your half of the crops except the Melon and Cucumbers which were sent to you."

GARDEN STRUCTURES.

A COMBINED HEATING AND FIRE-EXTINGUISHING APPARATUS.

A new heating and fire-extinguishing apparatus has been brought under our notice by Messrs. Smeaton & Co., horticultural builders, Fulham, which we think well worth the attention of householders and others interested in the preservation of buildings from destruction by fire. Messrs. Smeaton have just completed a contract, amounting to over £7,000, at Hertford House, for Sir Richard Wallace, who is anxious to ensure the safety of his pictures and other art treasures. The plan is a simple one, and consists of a hot-water heating apparatus and cold-water service apparatus, so connected by a system of self-acting double-action valves that the heating apparatus acts independently of the cold-water apparatus, and the latter independently of the former; while at the same time, should a fire arise, and the hydrants be opened at any one or more points, the valves come into instant action, and render available the whole of the water in both apparatuses, as also that which may be received from any external force from street mains or other supply; and further, should such force be greater than that obtained from the pressure exerted by the columns of water, the valves adjust themselves, and render the full amount of such extra pressure available. The advantage to be derived from the efficient action of such an apparatus will be obvious; among them

may be mentioned the certainty of having a large supply of water at command the moment an outbreak of fire is discovered, when frequently a few gallons ready to hand would be of more use than fire engines half an hour later. A good idea of the apparatus will be gained from the annexed illustration showing the section of a warehouse to which it has been applied. A is a hot-water cistern to act for service and expansion. B

—A cold-water cistern one or more of which may be used. C—Ball-cock and loop service to cold-water cistern. D—Safety expansion and circulating box in connection with hot-water cistern. E—Self-acting double-action valve, stopping the communication of hot-water to cold-water cistern, and opening to admit supply to heating apparatus. F—Cold-water services for general household or other purposes. G—Self-acting double-action valve to regulate supply and exhaust of cold-water cistern, by which the whole weight of water in the cisterns is available for the hydrants should the pressure be off from the main, while it prevents overflow if the pressure is on. H—Fire hydrants, of any number and in any position. J—Boiler of hot-water apparatus. K—Self-acting double-action valve preventing the cold-water passing into the heating apparatus whilst allowing the water in the heating apparatus to pass to the cold-water apparatus, and so become available for hydrants connected with it. L—Self-acting double-action valve retaining the whole of the water in the cisterns and pipes in case of the mains being emptied, or the pressure reduced below that exerted by the head of water in the cisterns. M—Cold-water service from street mains or other supply. N—Vertical service column to cisterns. O—Hot-water pipes, which may be fixed above or under the two floors and so arranged that they may be heated in sections or altogether as may be required. P—Vertical hot-water mains from boiler to safety expansion circulating box in connection with hot-water cistern.—*Building News.*

Raising Water.—I have two ornamental pieces of water, one 200 yards and the other 300 yards from the front of my house; would any of your readers be kind enough to tell me how to lift the water to the top of the house, otherwise than by hydraulic force? If a water-ram is anything to the purpose, would some one describe it?—F.

THE FRUIT CROPS.

METROPOLITAN AND EASTERN DIVISION.

Kent.—**Bridge Castle Gardens, Tunbridge Wells.**—Apricots, very scarce; Apples, fair crop; Pears, excellent; Plums, most abundant; Cherries, a capital crop; Strawberries, good, but did not last on account of want of rain and great heat; Peaches, an average crop; Gooseberries, good; Currants, plentiful; Filberts, scarce; Raspberries, plentiful and good; Figs, good, saved this year by being protected with nets in April.—J. RUST.

—**Preston Hall, Aylesford.**—April and May frosts were more or less destructive to fruits in this neighbourhood; nevertheless, Strawberries are a fair crop; Currants, Gooseberries, and Raspberries, abundant; Apricots, Apples, Pears, Plums, Peaches, Nectarines, and Nuts, all very thin crops.—WILLIAM BRADLEY.

—**Chevening Park, Sevenoaks.**—Apples, Apricots, and Peaches, a quarter of a crop; Cherries, half a crop; Pears, Strawberries, Raspberries, and Gooseberries, good crops; Plums, a great crop; Walnuts, Filberts, and Damsons, a failure; Currants, good.—D. COE.

Hampshire.—**Heckfield Place, Winchester.**—Apples are, generally, a light crop; Apricots are a heavy crop; Cherries, especially Morellos, good; Peaches and Nectarines have not been so good for years; Pears are about half a crop, and will be small; Plums of all kinds, heavy, both on walls and standards; Currants, red, white, and black, very heavy crops and fine in quality; Gooseberries and Raspberries were never better; Strawberries, where not cut off whilst in bloom by frosts in the end of May, are very heavy crops; Nuts, almost a total failure.

For blight of all kinds, for severe frosts in May and June, and for drought, this year is the worst I have ever known; yet, notwithstanding this, our fruit crops may be pronounced, upon the whole, satisfactory. Water has been used *ad libitum*, and Peaches, Nectarines, Apricots, and Pears, were well protected early in the season.—W. WILDSMITH.

—**Strathfieldsaye, Winchester.**—Fruit crops here are somewhat variable. Apples and Pears with me are not quite half a crop; but, in some places in the neighbourhood, less liable to late frosts, I have seen very heavy crops of these fruits. Peaches and Apricots, all protected here with good canvas coverings, are most

abundant, and, strange to say, notwithstanding the most ungenial season I ever knew, the trees appear healthier than I have ever seen them for many years. On walls, Cherries and Plums are plentiful; but, on standards, an absolute failure. Of small fruits, Raspberries, have produced a heavy crop; Gooseberries and Currants, rather a light one. Strawberries have been sadly deficient and late, the frosty nights of May having destroyed all the earliest and strongest blooms, consequently we have not half a crop.—JAMES BELL.

Surrey.—**The Denbies, Dorking.**—Apricots, a partial crop; Apples, on espaliers, an excellent crop in some cases, on many standards not a fruit; Pears, abundant, and promise to be of excellent quality; Plums, on wall-trees a good average crop; under glass abundant; Strawberries, abundant, and of excellent quality; Cherries, moderate—trees much blighted; Peaches and Nectarines, a good average crop—trees much blighted; Figs, very few are grown here on the open walls; Currants, Gooseberries, and Raspberries, abundant, and good in quality; Walnuts, a good crop; Nuts, very plentiful.—JAMES DREWETT.

Berkshire.—**Royal Gardens, Frogmore.**—Apples, partial, say about an average; Apricots, heavy crop and good in quality; Cherries, plentiful; Currants, good; Gooseberries, abundant; Pears, a fine crop and clear from smut; Plums, plentiful; Peaches and Nectarines, good crops and apparently of excellent quality; Raspberries, fine crop, but suffering from heat; Strawberries, light and of short duration; Walnuts, below average, killed by spring frost.—THOMAS JONES.

—**Coleshill, Shrivenham.**—Apples, thin—say about half a crop; Apricots, plentiful; Cherries, a fair crop, but very much

Smeaton's heating and fire extinguishing apparatus.

spoiled by late frosts and black fly; Currants (red), thin and small, (white) good, fine, (black) abundant and large; Figs, plentiful; Gooseberries, good and of fine size; Mulberries, plentiful; Nectarines, a fair crop; Peaches, plentiful—trees much blighted and sickly; Filberts, scarce; Pears, some early kinds plentiful, but late kinds very thin, having suffered much from late frosts; Plums, scarce, with the exception of Damsons, which are plentiful; Raspberries, plentiful, but small; Strawberries, about half a crop, and not nearly as fine as usual, the first blooms having been cut off by late frosts; Walnuts, very thin.—HENRY ECKFORD.

SOUTH-MIDLAND DIVISION.

Huntingdonshire.—Ramsey Abbey.—As far as regards quantity, our fruit prospects are most favourable; but the prolonged drought has had a bad effect upon both size and flavour, and, as might have been expected from the character of the season, insects have been more than usually troublesome. Apricots are an excellent crop; in fact, on an east wall they set much too thickly, and many had to be taken off. In a difficult season like the present, there is a considerable advantage in having trees in different aspects. I believe, indeed, that in some places Apricots would do well in a north aspect; I intend trying them there, with the view of prolonging their season. The blossoms also in a severe spring would probably escape injury from frost on such an aspect. Peaches and Nectarines are a moderate crop, and in this scorching weather, in the full glare of the sun on a south wall, even when heavily mulched and water freely used, it is difficult to keep the trees free from red spider and in good growing condition; Plums and Cherries are good but small; Gooseberries, Currants, and Raspberries are abundant, but smaller than usual; and the same remark is also applicable to Strawberries, which are, moreover, somewhat deficient in flavour; Apples are a fair crop, but small; Pears are thin, so also are Nuts of all kinds.—E. HOBDAV.

Hertfordshire.—Moorpark.—Apples, moderate, owing, doubtless, to the sharp frosts which occurred during the blooming season; Pears, fair crop; Plums, heavy crop; Strawberries, abundant on plants forced last year and planted out 3½ feet from row to row, and 18 inches asunder in the row, the ground being trenched 3 feet deep; Cherries, May Dukes, Bigarreus, and Early Sweet Cherries on walls, good crops; Morellos, very much attacked by black fly; crop indifferent; Peach and Nectarines tree (out of doors) moderate, much blighted in the first part of the season, clean and good in Peach-houses and orchard-houses; Figs, not a good crop; Gooseberries, very heavy crop; Black and Red Currants, good; Raspberries, soon over, owing to the dry and hot weather.—D. CUNNINGHAM.

Oxfordshire.—Great Tew, Enstone.—Red, White, and Black Currants, Gooseberries, Raspberries, and Strawberries abundant; Cherries, May Dukes and Bigarreus, a full crop; as are also Plums of all sorts; Pears, an average crop; Apples, about a quarter of a crop; Apricots, none; Peaches and Nectarines, very few; in our orchard-house full, as usual; we, therefore, feel the comparative loss of out-door crops the less, and can have always plenty of dessert for nine weeks, from the end of July till the beginning of October.—A. MACFARLANE.

Buckinghamshire.—Wycombe Abbey.—Apricots, a good average crop; Apples, a fair crop in some places, in others scarcely any; Pears, abundant; Plums, plentiful and good; Strawberries, the earliest and largest fruits destroyed by frost, crop good, but has suffered in many places from want of rain; Cherries, in low situations, very abundant and fine, on high-lying ground, small; Peaches and Nectarines, good crop; Figs, a fair crop; small fruits, abundant and good; Nuts, not plentiful; Walnuts, plentiful in some places, scarce in others.—G. T. MILES.

Northampton.—Castle Ashby.—Apples, in the garden here, a total failure, owing to the bloom having been all destroyed by spring frosts; Pears upon walls, a medium crop, but we have no fruit upon pyramids, of which we have a fine lot of well furnished young trees; upon young espaliers, there is a nice little crop; Plums, abundance of all kinds; Peaches and Nectarines, very few, trees suffered from cold and frost after having made their young growth, also fearfully infested with greenfly, which, to keep in check, requires a considerable amount of labour and attention; Morello Cherries set abundance of fruit, and all went well with them up to the stoning season, when they failed to perform that process; consequently, they dropped off, and are now a very poor crop; Currants, red, average crop; black, very inferior; Gooseberries, average crop, but inferior in quality; Raspberries, very bad indeed, the frost and cold nights in May having completely paralysed the young growth, from which they have not yet recovered; consequently, they have produced small pea-sized hard bits of fruit, and the canes are now in a semi-lifeless state; Apricots, very satisfactory, having been well protected during the severe frost of April and May by means of temporary covering;

Figs on walls, a few; Cob Nuts and Filberts, none; Walnuts, a few. With the exception of a few Horse Chestnuts, we have seed on no other forest tree on the place. This season will be recollected by all connected with horticulture as a singularly unfavourable one.—GEORGE BEECH.

—**Burghley, Stamford.**—Plums, particularly Greengages, an excellent crop; Peaches, half a crop; Nectarines, half a crop; Strawberries and Gooseberries, full crop; Currants, abundant; Figs, scarcely any; Nuts, very scarce; Medlars, full crop. These remarks relate to outside crops; but inside, Peaches and Nectarines are very fine, thus showing the desirability of growing such fruits in cool houses. Our third house (just in) contains Peaches measuring 10 inches round. Strawberries have not more than half come to perfection, in consequence of the dry weather. We have only had occasional slight showers since April. Apples are a short crop in this locality, and Pears, in some places, are a full crop, while in others they are very thin.—R. GILBERT.

WEST-MIDLAND DIVISION.

Worcestershire.—Witley Court, Stourport.—Up to May, seldom had we seen a greater promise of an abundant fruit crop of all kinds than this year. The previous summer and autumn having been favourable for the ripening of the wood, and the early part of this year all that could have been wished, there was the greatest possible profusion of bloom, which, however, got damaged by the bitterly cold and frosty weather that set in with May and continued throughout that month and June. Fruit trees, too, suffered severely from the persistent attacks of legions of aphides and other insects. Apricots are, therefore, but an average crop, even where thoroughly protected; upon cottage walls, they have suffered severely from frost, and are very scarce; Apples, half a crop, except in the case of trees in high-lying positions, on which the crops are, in some instances, heavy; the trees have suffered much from blight; cider Apples, very partial; Pears, scarce and partial, early blooming sorts best; Plums, scarce and very partial; we have average crops of Damsons, but they are by no means general; Strawberries with us have been a good crop, but generally they are light and partial; in some districts the bloom was caught by spring frost. We have an abundant supply of water, which has been of great service to Strawberry crops this season. Our best cropping sorts have been—President, a great bearer; Lucas, first-class in flavour, a good bearer, and a kind that carries well; John Powell, a free and useful sort; Dr. Hogg, fine in size and of first-class quality; Sir J. Paxton, and Mr. Radclyffe, a good strain of British Queen. Of Cherries upon walls, such as Morellos, there are full crops; upon standards, such as the Kentish, an abundant crop, but, in general, Cherries are a light crop, poor in size, and equally poor in quality; Peaches and Nectarines, on open walls, where protected, are fine crops, trees, too, clean and promising; Figs upon walls, an average crop; Gooseberries, full average crop; Currants, Red and White, under average; Black Currants, much blighted, and quite a quarter of a crop has fallen; Raspberries, full average crop; Walnuts, quite destroyed by frost; Filberts, half a crop, red-skinned by far the best crop. I may add that early Potatoes are fine, both in crop and quality, that late sorts are suffering from drought, and that I fear the crop will be poor, even should we now have rain.—GEO. WESTLAND.

Worcester.—Apples, partial; Pears, fair crop of early sorts, but not many of late kinds; Plums, rather scarce; Cherries, plentiful but small; Peaches, Nectarines, and Apricots, not many; Gooseberries and Currants, good crops, but blighted; Raspberries, plentiful; Strawberries, not abundant, fruit small.—RICHARD SMITH.

Gloucester.—Tortworth, Wootton-under-Edge.—So far, this has been a season of extremes, and against cold, heat, and drought, vegetation has had a constant and hard struggle; nor is there the least sign of such unfavourable conditions drawing to a close. Day after day the heat is so intense, that almost every kind of fruit tree is yielding to its effects. Should rain be delayed much longer our green crops will be a failure, particularly on shallow soils where water is scarce. In this neighbourhood, and, indeed, throughout the county, the rainfall has been very limited. We have not had much more than three days' rain since the middle of March, and none whatever since the 3rd of July, when we had just sufficient to discolour the ground; nevertheless, Peaches and Nectarines on open walls, in the majority of cases, are fair crops, and by constant attention to watering, the trees are in excellent health. Apricots are a total failure. Of Plums, we cannot reckon on more than a third of a crop; still, some varieties are bearing freely. The same may be said of Pears, with the exception of the earlier kinds, about which there is little to complain. Apples are a full crop, and, in many cases, a very heavy one; but, in low lying districts, they are a good deal below the average. Cherries at one time promised well, but three parts of the fruit dropped during the stoning period, particularly in

the case of wall-trained trees. Strawberries are abundant, but to a great extent small and deformed. Bush fruits are abundant and highly flavoured, with the exception of Gooseberries, which have suffered from the intense heat. Nuts are plentiful, both cultivated and wild varieties.—ALEXANDER CRAMP.

Warwickshire.—Compton Verney.—Apples, very few; Pears, good; Apricots, average crop and fine; Peaches, good; Nectarines, average; Plums, heavy crop; Cherries, on walls a crop; Walnuts, killed by the frost; Strawberries, plentiful, but small; Raspberries, not good, want rain; Gooseberries, plentiful; Currants, fair crop; Nuts and Filberts, not grown; Figs on walls, average crop.—G. CRADDOCK.

Staffordshire.—Alton Towers, Cheadle, Stoke-on-Trent.—Gooseberries were a heavy crop, but they were nearly all cut off by frost on the 15th of June last; Currants, the same; Strawberries, abundant, but small; Raspberries, good, but suffering from drought; Apples, thin, say half a crop; Pears, pretty good; Cherries, plentiful, but small; Plums, good, with the exception of Damsons, which are thin; Peaches, thin, dreadfully blighted; Apricots, very good, but small. I may add that vegetable crops, including Potatoes, are generally good, with the exception of Carrots, which are very much blighted, but we are short of rain, and have had bitterly cold weather up to the end of June, on the 15th of which we had 4° of frost, and 10° on May 14th.—H. RABONE.

Keele Hall, Newcastle.—Apples, very thin; Pears, a good crop on standards and walls; Damsons, a good crop; Peaches and Nectarines, poor, very few grown on open walls; Raspberries, good; Currants, good; Strawberries, generally good, but small, owing to the continued dry weather; Cherries, good, especially Morellos on dwarf bushes, on which we find they bear better, and are less subject to insects, than trained as they usually are against a north wall; Gooseberries, good; Apricots, fair. We never remember so much blight—aphis, caterpillars, and honeydew—as this season. We are suffering from want of rain; in fact, we have had very little during these last six months, although this part is generally considered to have a wet climate.—W. HILL.

Witley Hall, Broseley.—Apricots, very good; Peaches, good; Nectarines, very good; Cherries, abundant; Apples, very fair; Pears, very good; Plums, very heavy crop; Filberts, moderate; Gooseberries, very good; Currants, good; Strawberries, very good, but small, owing to the dryness of the season.—W. H. WELCH.

Herefordshire.—Downton Castle, Ludlow.—Peaches, Nectarines, Apricots, and Plums, with us are good crops; Apples, about half a crop, being destroyed by frost and blight; Strawberries and Cherries, fair crops. On the Cherry orchards in this part of the country there was the finest blossom that has been seen for years, but most of it was destroyed by blight. Raspberries, Gooseberries, and Currants, about half a crop, having been destroyed very much by frost; Pears and Damsons are fine crops.—WM. LONDON.

Eastnor Castle, Ledbury.—Up to the beginning of May the fruit crops in this district were promising, Plums and Cherries having set thicker than I ever remember to have seen them. On the 9th of May and two following mornings we had very sharp frosts, which completely cleared our standards and pyramids of fruit, Rivers's Early Prolific Plum excepted, which appears to be one of the hardiest, as well as one of the earliest, varieties we have. On walls we still have a good crop, but the trees have been much injured by aphides, and they are now suffering from the extreme drought. Apricots, however, turn out to be a much better crop than was at one time anticipated, many of the latest blossoms having set and swelled after the prominent blooms were destroyed. Early kinds are now ripening fast, and the sweet-kernelled Kaisha is unusually fine and transparent. Peaches and Nectarines are a partial crop, the cold wet season of 1873 having been unfavourable to the formation and maturation of perfect blossom buds; indeed, it was by no means unusual this spring to find such shy kinds as Barington, Wallburton, &c., entirely without bloom buds, except in very warm situations. Aphides have been unusually troublesome, but where they have been kept in check, and mulchings have been attended to the trees are looking well. Cherries are a thin crop, and the fruit has dropped more than usual, black fly being very troublesome. Apples are very scarce and poor, except on elevated spots that were well sheltered from the north, and this being a great cider-making county even partial failure in the Apple crop is a serious loss. Pears are rather more promising, but the fruit is small, no rain having fallen to affect the roots since April. Bush fruit is plentiful and good, with the exception of Black Currants, which are badly blighted. Strawberries were much injured by the May frosts, and a continuance of dry weather, while improving the flavour, has seriously reduced the quantity and duration of this useful fruit. Raspberries fall below the average. Nuts are scarce. Walnuts partial; many of the trees were killed back when they had made

4 inches of young wood, and it was nearly midsummer before they showed signs of returning vitality. I may add, that up to the present time vegetables have been plentiful and good, but we may now expect a falling off. Potatoes are short in the top, look healthy, and promise a fair yield of medium-sized tubers of first-rate quality.—W. COLEMAN.

NORTH-MIDLAND DIVISION.

Leicestershire.—Coleorton Hall, Ashby-de-la-Zouch.—Apricots, very light in this quarter; Apples, very good; Pears, very good on walls, thin on standards; Plums, unusually heavy crop; small fruits of all sorts abundant, but small from want of rain; Cherries, a very great crop; Peaches and Nectarines, both rather thin (were over-cropped last year); Figs, a good crop, but look as if they would drop off, owing to the excessively dry weather; Strawberries, plentiful, but small—half of the crop unable to swell, owing to the drought, which has killed many of the plants outright; Nuts, very few indeed.—M. HENDERSON.

Nottingham.—Wollaton Hall.—Apples are a light crop, having been much injured by frost in May; good dessert kinds will be scarce, although when in bloom there was every appearance of heavy crops; of Apricots there is a good average crop from late blooms, the first blossoms having been entirely killed—trees healthy; Peaches and Nectarines, light; during May the trees were much infested with aphides, but now they are doing well; of Plums there are good crops, especially of the better dessert sorts, but the trees were badly attacked with aphides early in the season; Damsons, very scarce; Cherries, good, but suffering from want of rain to swell them off properly; Pears, early and mid-season kinds, plentiful, late sorts scarce; Filberts, none; Walnuts, scarce, having been killed by frost; of Gooseberries there is a very heavy crop in the neighbourhood, but the trees are much infested with caterpillar; Strawberries, moderate, having been much hurt by frost, and dried up since; Red and White Currants, good crops and clean, Black scarce; Quinces, none.—HENRY GADSDEN.

Lincolnshire.—Belvoir Castle, Grantham.—The crop of that most valuable of all hardy fruits, the Apple, is by no means a full one; indeed, I do not think that it can be called half a crop, and the drought may still lessen it. Late-blooming trees of large size and mature age afford the best crops. Amongst other sorts that have fair crops may be mentioned Bess Pool, Northern Greening, Caldwell, Blenheim, Herefordshire Pearmain, and Keswick Codling. Of Pears there is a very good general crop, especially on the most healthy and vigorous trees. Williams's Bon Chrétien, Marie Louise, and Louise Bonne of Jersey are very full. Of Plums there are fair crops of Victoria, Jefferson, and Golden Drop on walls. Standard trees generally have failed; but few Damsons. As regards Cherries, there are abundant crops of May Duke, Morello, and Kentish; but they are greatly injured by blight and drought. Of Peaches there is a moderately good crop—trees healthy. Of Figs, there is a very good show of fruit. Apricots, scarcely half a crop, a portion of the fruit having fallen owing to the dry state of the borders; Strawberries, very abundant, but small; Raspberries, a very full crop, but suffering from drought; Gooseberries, a very full and satisfactory crop; Currants (red), a moderately good crop, (black) rather small.—W. INGRAM.

Sudbrooke Holme.—Apricots, an average crop; Peaches, a failure—trees unhealthy through cold and fly; Plums, an average crop; Pears, Marie Louise, Winter Nelis, and Williams's Bon Chrétien are good crops, but all other sorts scarce; small fruits, such as Currants, Gooseberries, Raspberries, a full crop; Black Currants, scarce; Cherries, of all kinds, an average crop; Apples, in general, under an average, but in some orchards a good crop, though both these and Pears will be small this season owing to the drought; small fruits, in cottage gardens, scarce; every kind of crop is suffering from want of rain.—GEORGE MCLEAY.

SOUTH-WESTERN DIVISION.

Cornwall.—Enys, Penryn.—Apples appear to be an average crop; Pears are rather above the average, but, judging from present appearances, will be small; Peaches and Nectarines, below the average; Cherries, about an average; Plums, kinds for preserving, below the average; other kinds, about an average; Figs, poor; Strawberries, a good crop, but soon over, owing to the drought. Bush fruits of all kinds, a good crop; Raspberries, good.—HENRY MILLS.

Dorsetshire.—Sherborne Castle.—Apples here are a very fair crop; Apricots, half a crop; Berberries, plentiful; Cherries, a fair crop for the neighbourhood; Currants, half a crop, very much damaged by the late frosts; Figs, moderate; Gooseberries, half a crop, damaged by the late frosts; Medlars, a fair sprinkling; Nectarines, in the open air, a very middling crop, and the trees are in a very

bad condition—indoors, very good; Nuts and Filberts, scarce; Peaches, a very middling crop, trees in bad condition; Pears, a moderate crop; Plums, plentiful; Quinces, a middling crop; Raspberries, very plentiful; Strawberries, very good, but small, owing to the drought; Walnuts, plentiful in some places. I may add that Potatoes are looking uncommonly well this season, a singular fact, when most other vegetable crops are suffering from drought. The Corn is looking remarkably well, but root crops are almost a failure.—W. G. PRAGNELL.

Devon.—Exeter.—Peaches and Nectarines, moderate; Apricots, below average; Plums, abundant; Pears, Apples, and Strawberries, average crops; Black Currants, below average; Red and White, average crops; Raspberries, good; Nuts and Filberts, abundant; Cherries, abundant; and Figs, scarce.—JOHN GAPLAND.

Somersetshire.—Ashton Court, Bristol.—Apples are a good average crop, early kinds being more plentiful than late ones; Apricots, light crop; Cherries, plentiful, but much blighted; Currants, red and white, very fine and heavy crops; black, light and much blighted; Figs, generally good; Gooseberries, heavy crop; Medlars, every prospect of a heavy crop; Mulberries, good; Peaches and Nectarines, good on open walls (where protected in spring under glass), also large and well flavoured; Nuts, very light; Pears, good, and, for the season, remarkably clean and fine; Plums, poor and much blighted; Raspberries, good, but small; Walnuts, scarcely any; Strawberries, an average crop, which suffered much from drought. Fruit trees and crops generally are much blighted and greatly in want of rain.—JOHN AUSTON.

Merriott, Crewkerne.—We have here a fair crop of most kinds of fruit. Apples, in both gardens and orchards, will, I think, be a good crop, say half the quantity we had last year, which was just one half too much for the good of either the trees or the growers. Apples were nearly unsaleable, such was their abundance; but, thanks to railways, the "black country" and large towns absorbed a considerable portion, and the cider barrels, with some difficulty, held the rest. One thing this season, notwithstanding the adverse weather we had up to the end of June, trees generally look healthy and are covered with fine foliage, consequently, the quality of the fruit will be finer than it otherwise would have been, a circumstance which will make up for quantity. Pears grafted on the Quince are nearly a failure this season, while those grafted upon the Pear stock are loaded with fruit; it was just the reverse last season. Plums of most sorts, on open standards, are a good crop, in some instances weighing down the branches; I have noticed this season that the woolly and hairy-leaved kinds have resisted the frost better than the smooth and shining-leaved sorts. Cherries, especially May Dukes and Morellos, are bearing heavy crops, but we are sadly tried to know how to save them from blackbirds, through whose depredations we lose more than half our fruit crops. Gooseberries, Currants, and Raspberries are, and have been, abundant; Strawberries, owing to want of rain at blooming time, are only a partial crop. We have had little or no rain here for three months; we had a good fall at the end of June, but that on the 29th was accompanied by a thunderstorm, which, in a few instances, started the Potato disease. Field crops in this neighbourhood are very fine, and give great promise of an abundant harvest.—JOHN SCOTT.

Nettlecomb, Taunton.—Up to the last week in March fruit crops promised to be abundant, but April set in accompanied by cold easterly winds, and, occasionally, rain, hail, and snow until the latter part of the month, when we had a week or ten days of summer weather, which very much improved the fruit crops, and trees on walls were recovering fast. May, again, brought us cold easterly winds and sharp frosts at nights, and these unfavourable conditions continued, more or less, for three weeks in June. There was, however, little or no rain or the crops would have suffered much more than they have done; still, the cold frosty weather did much damage, both to fruit and vegetable crops; nevertheless, Apples are a good crop, particularly the better sorts; Pears, above an average crop; Plums, in some places, plentiful, in others scarcely any; Strawberries, where kept well watered, are a fair crop and of fine quality; Cherries, good and fine, particularly May Dukes and Morellos; Peaches and Nectarines, in some places, are a fair crop, in others, scarcely any; Apricots, here and there, are a good crop, where protected, otherwise indifferent; Figs, outdoors, abundant; Walnuts, scarcely any, trees much injured by frost; Filberts and Kent Cob Nuts, scarcely any; Quinces, none; Medlars, an average crop; Black Currants, an average crop; White and Red Currants, below average; Gooseberries, very good; Raspberries, in some places, an average crop, in others, much under average.—CHARLES ELWORTHY.

Wiltshire.—Wilton House, Salisbury.—Apples hereabouts are a bad crop; Apricots, a medium crop; Cherries, a fair crop; Currants and Figs good; Gooseberries, fair; Medlars, thin; Mul-

berries, trees much injured by spring frosts; Nectarines and Peaches good; Nuts, a fair crop; Pears, partial; Plums, abundant; Quinces, a light crop; Raspberries, thin; Strawberries, poor; Walnuts, bad. There was perhaps never a better prospect of fruit, of all kinds, than this year at the end of April, and perhaps it would be impossible to find on referring to reports of past years, a more destructive month than May proved to be this year; one favourable condition, however, was the almost total absence of rain, of which only $\frac{1}{2}$ inch fell in May. Had we received the usual amount with such frosts and bright sun, total failure must have been the result. Frosts occurred on fifteen nights in May, the most severe being on the 10th, 11th, 17th, and 18th, when the glass registered 6° of frost on the two former, and 4° on the two latter nights, but owing to the clear sky which prevailed throughout the month 12° of frost were frequently registered on the ground by the thermometer when exposed. A variation of 90° often occurred between the mid-day solar heat, and the minimum heat on the surface of the ground at midnight; on the 18th the solar heat reached 125°, and the minimum on the same day on the surface of the ground was 23°, a difference of 102° in twelve hours.—T. CHALLIS.

MIDLAND DIVISION.

Derbyshire.—Chatsworth, Chesterfield.—Apples with us are about a quarter of a crop; Cherries, on walls, a crop, but those on standards when in bloom suffered severely from frost; Currants, red and white, are a full crop, but black kinds suffered from the frost on May 16th; Gooseberries are about half a crop; Plums, none; Pears, a thin crop; Peaches, none grown out of doors here; Raspberries, half a crop; Strawberries, an abundant crop. The frost of May 15th was most destructive to Pears, Apples, and Plums; we registered 10° of frost on the 16th, and 9° on the 17th of May, and the cold winds, which blew from the north-east twenty-one days consecutively, were most detrimental to both fruit and vegetables, and considering that we had only 3·81 of an inch of rain between the 1st of March and the 12th of May, it has been one of the most trying seasons for outdoor gardening that I ever remember.—THOS. SPEED.

Osmaston Manor.—Apricots here are a good crop; Pears, very good; standard Apple trees are loaded down with fruit; Strawberries, very good and large; Cherries, excellent, both on standards and walls; Plums, including Damsons, a very large crop; red and black Currants and Gooseberries, heavy crops; Raspberries, good; Peaches and Nectarines, not grown out of doors here.—J. BOOTH.

Nottinghamshire.—Welbeck Abbey, Worksop.—Apple trees in this district produced an extraordinary abundance of blossoms, but spring frosts and insects have sadly thinned the crop, which can hardly now be called an average one. Pears, on standards, are likewise only thinly cropped; but on walls these are abundant. On a wired trellis, in the kitchen garden here, both Pears and Apples show very heavy crops. Plum trees furnished plenty of blossom, and the fruit escaped the ungenial weather in May and June better than Apples and Pears have done; very heavy crops of Plums are, therefore, now to be seen in many orchards. Cherries have been a fair average crop, and on north walls Morellos are abundant; Apricots, Peaches, and Nectarines, on walls, where protected, are abundant, and required a great deal of thinning; Raspberries and Currants are well cropped, but the fruit is small, having suffered from the continued drought in June. Legions of aphides have likewise attacked the foliage of Currants, so much that the bushes are nearly bare. Strawberries, where well attended to with watering, have produced excellent crops, and I find President, Sir J. Paxton, Lucas, Sir C. Napier, British Queen, Dr. Hogg, Frogmore late Pine, and Elton still the best varieties for general crops. No variety equals the Grovend, or Old Scarlet of some, for preserving, as it ripens early, and has a fine red solid flesh. Filberts and Cob Nuts are a failure here, but they are not grown in any quantity.—WILLIAM TILLEY.

Berry Hill, Mansfield.—Considering the cold spring and long drought which we have had, fruit crops, or the whole, may be set down as a fair average. Apples are a fair crop; Apricots, good; Cherries, a fine crop, especially Morellos, which are very heavy; Peaches, a good crop, but very late; Plums, very fine; Strawberries, abundant, but fruit small; of what are called small fruits, there are good crops; Walnuts, very thin, having been cut off by frosts; Filberts, also a light crop.—S. A. WOODS.

Lincolnshire.—Bloxholm Hall, Sleaford.—Apricots, abundant where protected; but, where unprotected, even on the same aspect, they were destroyed by spring frosts; Apples, a complete failure, only a few being observable in sheltered corners. The blossoms on Apple trees were plentiful and strong, and great hopes were entertained of an abundant crop, but a succession of frosty nights occurring when they were in bloom completely destroyed them; Pears, some varieties an average crop, but, in general, under

average, and I am afraid that the quality will be indifferent; Plums, on open standards and bushes, a complete failure, but where protected on walls, a fair crop; Peaches and Nectarines, where protected, a fair crop, but the trees in some parts are very much blighted; Cherries, under an average, having been much destroyed when in bloom by severe frosts in May and June; Strawberries, a good crop and fine, but their season will be one of short duration owing to the hot dry weather; Figs, under average; Gooseberries, a fair crop, and of good quality, although they were very much injured in some localities by late spring frosts; Raspberries, abundant and fine, but will be of short duration; Red Currants, under an average, having been very much destroyed by spring frosts; White Currants, a fair crop; Black Currants, under average; Walnuts, variable, some trees having a fair crop on them, while others show none; in most cases the young shoots were killed by sharp frosts in May; Nuts, under average, not much grown here. The fruit season this year will be a memorable one. In spring we had an abundance of bloom, Apples, Plums, and Cherries, were completely covered. The month of April being mild, vegetation progressed favourably, but from the 1st May to the middle of June we had scarcely one night free from frost accompanied by cold biting east and north-east winds which have proved very destructive to fruit crops. On Monday the 18th May we had 12° of frost, Potatoes and Kidney Beans were cut to the ground and again on June the 12th we had 11° of frost, which again cut down Potatoes, Kidney Beans, and other vegetables. Pears, Apples, Cherries, and Gooseberries dropped in quantities from the trees, blighting all our hopes.—DAVID LUMSDEN.

NORTH MIDLAND.

Lincolnshire.—Aswarby Park, Folkingham.—Among Apples, Ribstons are a full crop, all other varieties about a quarter of a crop; Currants, red, white, and black, full crop, fruit of the black small; Figs, a full crop, fruit large and fine, several ripe fruit having been gathered from outside walls; Gooseberries, all growing on a north border, are a heavy crop, fruit very large; Apricots are a heavy crop, fruit large, changing colour fast; Mulberries, full crop; Pears on walls, half a crop; on trees, trained as pendulous standards, a full crop, having only missed a crop once in thirteen years; Nectarines, a fine full crop, foliage much blistered; Peaches, very poor, fruit of the Early Beatrice on a wall now ripe; Plums, quarter of a crop, suffered badly from late frosts, Rivers's Early Prolific now ripe. The rainfall between January and March has been 3.02, between April and June 1.36, while from June up to this time we have had none; everything in this neighbourhood is, therefore, suffering from want of rain. A large farmer near here has turned his stock into a field of Wheat, and my employer turned his lands into a 10 acre field of Oats; in the village of Scredington, 2 miles from here, they have to pay 1d. for each bucket of water for domestic use; the laws here have not been mown for these last eight weeks; carpet-bedding is doing well here, but ribbon-bedding is almost a failure. Last week, our rector told his gardener to save all water, as it was likely to be wanted for domestic purposes, and to let the kitchen and flower gardens take their chance.—RICHARD NISBET.

Rutland.—Exton Park.—Apples and Pears are scarce in most gardens in this neighbourhood; Cherries are abundant; Peaches and Nectarines are a very poor crop, the frosts on the 10th, 11th, and 12th of March, when we had 12° and 5° of frost, caught them while in bloom and killed all the flowers, even when covered with branches and other kinds of protecting material; Strawberries are a good crop, but have suffered much from want of rain; President, Vicomtesse Héricart de Thury, and Elton Pine, have withstood the dry weather better than any other variety; small fruits are a splendid crop, Red and White Currants being larger and finer than ever we have known them to be here. The fruit is large, clean, and has ripened well. Black Currants are abundant, but very small. Gooseberries are a remarkably fine crop, and the bushes are clean and healthy; Raspberries, good but small, owing to continued hot dry weather; Filberts and Walnuts are very scarce.—J. SMITH.

EASTERN DIVISION.

Suffolk.—Culford Hall, Bury St. Edmunds.—Peaches and Nectarines on the walls here are carrying a moderate crop of fruit, but the trees have been greatly blighted. In orchard-houses the prospect of fruit is much better. Apricots are a somewhat light crop, but the fruit, which is nearly ripe, is remarkably fine and large. Apples, in the gardens here and in this neighbourhood, are as nearly as possible, a total failure, and any small portions of fruit which there may be, will consist of the most hardy culinary varieties; numbers of trees of the finer dessert sorts are here trained to a low flint wall facing the west, and they are carrying about half a crop. Both standard and dwarf pyramid Pear trees are here much the same as

Apple trees—nearly destitute of fruit; while, on walls, nearly all sorts are in great abundance, and it has been necessary to thin out the fruit to a considerable extent. Plums on standard trees are also a failure; even the Damsun (which seldom fails here) has done so this season, while Greengages, Washington, and most other sorts trained to the walls are in great abundance, and have required thinning. Cherries—The only sort grown on the open walls here is the Morello, of which there is a moderately good crop; but they have been greatly infested with black fly. In the orchard-house the various sorts are abundant, and of good quality. Figs trained on the open walls are carrying a fair crop of fruit, which is likely to ripen. Grape Vines on the open walls show enough of fruit, which will, however, hardly ripen this season. Mulberry trees are carrying a light crop. Medlars are in great abundance; Quinces, very few; Walnuts, none; Filberts and other Nuts, a very light crop; Raspberries, abundant, and, considering the great drought which we have experienced, much finer than could have been expected; Gooseberries, in great abundance and very fine; Red and White Currants, abundant, and of excellent quality; Black Currants, light and inferior in quality; Strawberries, plentiful and good, but, on account of the dry weather, have not lasted long.—P. GRIEVE.

—**Wolverstone Park, Ipswich.**—Fruit crops in this district are very variable, and are suffering from want of rain. Pears on the Quince stock have set full crops, except in exposed situations; but a large percentage of the fruit is frost bitten and deformed, and, when rain comes, I fear a good many will split. Those on Pear stocks and trained on walls are more satisfactory, and, being deeper rooted, have not suffered so much from the dry weather. Plums are thin on standards; but, on walls, have set full crops. Many of these are now falling, and others are swelling very irregularly, owing to the tender fruit having been injured just after setting. Strange to say, Apricots passed safely through this trying ordeal, and have set full crops; while the trees are freer from gum than I have seen them for years. Peaches and Nectarines are very thin, and the trees have suffered severely from the constant checks to growth which they have had, and persistent attacks of aphides; indeed, I do not remember a season when the latter have been so numerous, or so difficult to eradicate as the present; Cherry trees are bearing fine crops, and the fruit is of good quality; Figs showed enormous crops, but the more tender kinds, such as White Marseilles, have all fallen off, while the dark kinds have retained a fair crop; Apples are variable, some kinds having set full crops, while others are very thin; wherever fully sheltered, the crops are up to the average, but the fruits are now falling, and will be small if we do not soon get a supply of rain; the crop of Strawberries has been most abundant, but, owing to the drought, the fruit did not swell to a large size; Gooseberries, Raspberries, and Currants are all heavy crops, but the latter are badly infested with green fly, and to escape an unusually heavy deposit of so-called "honeydew," I have had the tips of the shoots removed.—J. SHEPPARD.

—**Hardwicke House, Bury St. Edmunds.**—Apricots on walls here are between a half and a three-quarter crop; Plums, Peaches, and Nectarines, full crops in places; Cherries, all sorts, full crops here, in other places failures; Pears, a quarter crop; Apples, very partial, full crop on many trees, few or none on others; Mulberries, fine crop; Medlars, full crop; Nuts, partial; Gooseberries and Currants, full crops, and elsewhere entire failures; Raspberries, fine show, but suffering from late frosts and continued drought; Strawberries, fine crop, half a crop, and a complete failure, according to locality, latest sorts generally the best; President, Eleanor, and Elton, fine here; Keen's Seedling, British Queen, Black Prince, and old Scarlet, for preserving, almost a total failure; the whole of the early blossoms were blackened and ruined by June frosts. On walls I found glass copings most useful for Peaches, Nectarines, and Apricots. Trees under these are carrying good crops. Apricots protected by boughs on the walls, but under no coping, almost a total failure. The Impératrice Plum, too, is almost a total failure. Have other cultivators found its blossoms more tender than those of the Gages, Golden Drop, Jefferson, Victoria, Violette Hative, &c.? I almost forgot to add that out-of-doors Figs and Quinces are bearing capital crops.—D. T. FISHER.

Norfolk.—Cossey Hall, Norwich.—Apples here are good, but in some localities only very moderate; Pears, on walls and espaliers, are a fair crop, but on standards deficient; Apricots are abundant, but in some instances the fruits are falling off through drought at the roots; Plums are good on walls, but bad on standards; Figs and Cherries are only a moderate crop; of Peaches and Nectarines there are fair crops, but the trees are infested with insects and blight; Gooseberries and Currants are plentiful; Raspberries, good in some parts, but in others they have suffered from drought; and the same remark applies to Strawberries; Filberts are a fair crop, but of Walnuts we have few indeed.—J. WIGTON.

YORKSHIRE.

Thorpe Perrow, Bedale.—Apples here are a bad crop, all having been destroyed by May frosts; Apricots, abundant; Cherries, good; Currants, abundant; Filberts, bad; Gooseberries, an enormous crop; Pears, good; Plums, moderate; Peaches, good; Raspberries, moderate, suffering from want of rain; Strawberries promised to be good, but from want of rain the crop is inferior.—WILLIAM CULVERWELL.

Wortley Hall, Sheffield.—Apples, Pears, and Plums, a failure, in consequence of the scathing winds and frosts which prevailed when the trees were in flower; Cherries a fair crop; Apricots on walls, moderate; all Gooseberries and Currants, where netted in spring from bullfinches, good; but where not protected, bushes everywhere are entirely denuded of their buds; Peaches under glass are a very good crop.—J. SIMPSON.

Cleveland District.—The Apple orchards attached to almost every farm-house in this district, are bearing lighter crops than I have seen upon the trees for several years, and the same may be said of the Pear and Apricot trees that cover the walls of both the houses and cottages. In gentlemen's gardens, however, the reverse of this holds good, the fruit crops in these being abundant; Pears and Apples upon dwarf trees are remarkably good; Plums, most abundant in many places; Gooseberries, Black and Red Currants, a heavy crop; Strawberries, plentiful, but small; Cherries, a very indifferent crop, the trees nearly killed through fly and blight.—J. T.

Stourton Park, Knaresborough.—After the very variable season which we have experienced fruit crops are as good, with the exception of Apples, as could have been expected. Apricots are everywhere abundant; Peaches and Nectarines are fair crops; Pears, Plums, and Cherries are abundant. Here Pears and Plums are better on standards than on walls; both Plum and Cherry trees have suffered much from fly; Apples are, in general, a very light crop, some trees are producing fairly, whilst others have few or no fruit at all on them. With the exception of red Currants (which are smaller than usual and a lighter crop) bush fruits are abundant. Strawberries in the gardens here are an average crop, but the fruit, owing to the drought and heat, is smaller than usual; the Strawberries in general in this neighbourhood are, however, a light crop, the continued drought having been much against them.—M. SAEV.

NORTHERN DIVISION.

Northumberland.—Shawdon Hall, Alnwick.—Early in the season the promise of an abundant fruit crop in this county was great, but in many cases the result has not fulfilled our expectations. This is not to be wondered at when we consider that in the month of May and early part of June we had had continuous frost. During several nights in the latter part of May the thermometer registered 7° of frost. To the dryness of the atmosphere, and abundance of early foliage, must, I think, therefore, be attributed the fact, that we have an average, if not an abundant, crop of fruit in this county. Apricots are fully ten days earlier than usual, the fruit being in some cases in different stages upon the same tree, as owing to the severity of the weather they came into blossom at intervals of eight or ten days. Peaches are not extensively grown in this county, but such as we have appear to be a fair crop; the trees are, however, suffering from fly; Pears on walls are just an average crop, but the trees are healthy and robust; Cherries are all but a failure; where the trees are exposed to the east or south-east, they are suffering from fly and blight; Apples, like the Gooseberry crop, are abundant in some places, but scarce in others; Black and Red Currants are, in many places, a light crop; of late Strawberries, the crop is quite an average one; Raspberries are an indifferent crop, the fruit being small and bluish, and, in some cases, the plants are suffering from canker and curl.—J. THOMSON.

Durham.—Lambton Castle Fence Houses.—Apricots here are a heavy crop; Cherries, fine; Plums, an average crop; Strawberries, plentiful and good; Peaches, fine and plentiful; Nectarines, good; Apples, very thin; Pears, average; small fruits, plentiful.—J. HUNTER.

NORTH-WESTERN DIVISION.

Lancashire.—Croxteth Park, Liverpool.—Strawberries in this part of the country are abundant and good; Currants of all sorts are thin; Gooseberries and Raspberries are fair; Cherries (Morello), good, but injured through black fly, May Dukes and other kinds a fair crop; Plums, including Damsons, a failure outside, plentiful in orchard-houses; early kinds of Pears a good crop, later sorts here injured by frost in May; Apples, which also suffered from frost while in flower, are a thin crop.—J. BISSET.

Cheshire.—Crew Hall.—Apples, very few; Pears, very good crops generally; Plums, average on walls, scarce on standards;

Damsons, which are largely grown in this district, very scarce except in sheltered situations; Strawberries, good crop with me owing to their being well watered during the dry weather; Cherries, an average crop; Peaches and Nectarines, good in orchard-house and on protected walls; Apricots, scarcely an average crop; Gooseberries, Red Currants, and Raspberries, plentiful; Black Currants, scarce; Nuts, very few. The very low temperature in the latter part of April and nearly all through May and June, lower than I have ever known it to be here, caused many fruits already formed to fall off, and prevented Apples, when in bloom, from setting.—W. WHITAKER.

THE AMERICAN FRUIT CROPS.

We have received from the Department of Agriculture, at Washington, the report of the fruit crops for the year 1871:

The bloom of all orchard fruits has been generally abundant. The frosts of April, especially those of the 29th and 30th, were not too early in the Southern States to be harmless. They proved exceedingly destructive to fruit prospects throughout the entire region south of the thirty-ninth parallel and the Ohio River. There are exceptions in the vicinity of rivers and in other protected locations, but they are very few. Scarcely a southern county makes so positive a statement as Boone, Arkansas:—"Almost every tree is loaded. Thousands of bushels of Apples and Peaches will doubtless rot in the orchards." A reduced yield is the nearly universal expectation, and many reports indicate less than a fourth of an average crop, and some scarcely a tenth. In cases where the germ escaped destruction by frost the young fruit is rapidly withering and falling off to a very discouraging extent. In the Eastern States the bloom is generally quite full, but the fruit was not developed sufficiently to make a report of condition satisfactory. Reports from the fruit regions of Western New York, Ohio, Michigan, Missouri, Kansas, Texas, and California are variable, but of fully average promise. In Pennsylvania the prospect for fruit is generally good. Increasing attention is paid to fruit culture in some portions of this State. It is stated that in Wyoming County "millions of fruit trees and Vines have been set out within the past fifteen years, and all are loaded with bloom and set with fruit." Fruit culture is also attracting much attention throughout the South.

Apples.—The States reporting condition, average, or above, are as follows:—Maine, Ohio, Indiana, Kentucky, Texas, 101; Rhode Island, New York, Minnesota, 103; Vermont, Illinois, Wisconsin, 104; Iowa, California, 105; Pennsylvania, Missouri, Nebraska, 106; Michigan, 107; New Jersey, 111; Massachusetts, Kansas, 118; Connecticut, 119. Those below average:—Virginia, 59; Mississippi, 67; Louisiana, 75; North Carolina, 76; Georgia, 82; Alabama, 83; Delaware, 88; Tennessee, 90; Maryland, 92; Arkansas, West Virginia, 96; South Carolina, 97. There is some complaint of injuries from insects in different portions of the country. "Caterpillars are more numerous than ever" in New London County, Connecticut, and very abundant in other sections of New England, and the pest is reported "in countless millions" in Ripley, Ind. In Decatur, Iowa, "the leaf-roller has taken nearly half the Apples." The ravages of the measuring worm are also reported. In Montgomery, Ala., a blight similar to that affecting Pear trees is injurious to Apple trees.

Peaches.—The eastern Peach-growing regions do not present very favourable reports of condition. The average for Delaware is but 60; that of Maryland 61; and New Jersey is placed at 80. Mild weather in winter advanced the buds, and late frosts and sheets brought much injury throughout this belt. A report from Kent, Maryland, after the great April frost, stated that Peaches would be abundant; but ten days later, after the occurrence of further frosts, our correspondent wrote that there would scarcely be a fourth of a crop—a full crop of Hale's Early, but scarcely any of Crawford's Early or Crawford's Late. Hale's Early has also measurably escaped in Caroline and Queen Anne. A similar injury of late frosts is reported from Wisconsin and other Peach counties. The reports concerning the Michigan Peach region are favourable, and the average for each of the States west of the Ohio is not less than 100. The Middle States (excepting Pennsylvania), Ohio, and all the Southern States east of the Mississippi, will have a comparatively small production this season. The destruction was caused by frost and hail. The storm of the 29th of April, which was of snow as far south as Washington and throughout the plateaus of the South, was peculiarly destructive to young fruit or its germs. A portion of Indiana and Illinois report excellent prospects. It is reported from Jasper County, Missouri, that seedlings are a failure, while budded trees bear half a crop. In orchards of Bourbon, Linn, and Wilson, Kansas, the leaf is curling and the fruit dropping. The past winter has proved very destructive to Peach trees in Oregon, especially

those growing on a good soil, highly cultivated, and still worse on lands irrigated late in the season. In some localities in California the crops will be reduced by the effects of curled leaf and mildew.

Pears.—The condition of the Pear crop is below average in nearly all the States east of the Mississippi, the principal exceptions being Southern New England, New Jersey, and Pennsylvania. The bloom was abundant, but frosts proved very destructive. In Queen Anne, Maryland, "all are gone except some Seekels and Duchesses." In Anderson, Kentucky, "a large part dropped off." In Montcalm, Michigan, "the trees are about all dead, the effect of the winter of 1872-73"—a statement which is made elsewhere relative to Peaches as well as Pears. In the vicinity of Concord, Mass., the old favourite, the reliable Bartlett, has died out in numbers, and many others are visibly declining in vigour.

PEACHES AND NECTARINES ON THE SAME TREE.

It is a curious and by no means easily to be accounted for phenomenon, that of Peaches and Nectarines growing on the same tree—nay, sometimes even on the same branch; while stranger still is the record of trees bearing fruits, one-half of which was Peach, the other Nectarine. We have received a communication from Dr. Moore, of Glasnevin, enclosing a letter bearing on the subject from his friend, Sir Thomas Larcom, K.C.B., late Under Secretary for Ireland. Dr. Moore, in his note, remarks that "even in our advanced state of horticultural knowledge, few practical gardeners, or even the owners of gardens know that the Peach was originally a sport from a Nectarine;" adding that in the instance alluded to by Sir Thomas Larcom the sport has been reversed, the Nectarine occurring on the Peach. We shall let Sir Thomas tell his story:—

"Heathfield, Fareham, 7th July, 1871.

"MY DEAR DR. MOORE,—You gave me such satisfactory information some time ago about the four-leaved Shamrock that I am tempted to write to you to ask whether the Peach and Nectarine are akin to each other. This has occurred in the garden of a gentleman in our neighbourhood: a Peach tree, never failing to produce Peaches, bore last summer three Nectarines on a particular branch, on which branch there are now three Peaches. There is, I am told, for I have not visited or seen the tree, no appearance of the branch having been ingrafted. I confess I discredit the whole story, and take it for a fancy of the gardener. I do not know what is to come next, if fruit can grow by 'selection.' Do enlighten me.—Always sincerely yours,

"THOMAS LARCOM."

Dr. Moore remarks that the phenomenon must be of rare occurrence; as, though he has been for nearly half a century among fruit trees, he has never actually seen an instance of it; neither have we; but the fact is, nevertheless, indisputable. Mr. Rivers is of opinion that the Noblesse and some others of our best Peaches originated from the old White Nectarine. That comparatively new and fine Peach, Prince of Wales, was raised by Mr. Rivers from a stone of the Pitmaston Orange Nectarine; while of ten seedlings raised by him from stones of this same Peach, Prince of Wales, five turned out to be Peaches and five Nectarines; three of the latter being orange and two white-fleshed. Another eminent fruit grower has gone so far as to say he could produce the phenomenon by carefully removing the down from the surface of the young Peach when not larger than a Horse Bean, the result being a Nectarine in size, colour, flesh, and flavour. If any of our readers have met with a case of the kind this season (it has been thought to occur oftener in dry seasons), or can speak from previous personal experience, we shall be glad to hear what they have to say in the matter.—*Irish Farmers' Gazette*.

Vines from Eyes for Pot Culture.—I wish to know when the eyes of Vines should be struck for growing in pots in order to fruit in January, February, and March, and what are the best Vines for that purpose?—J. V. H. [Mr. Tillery, of Welbeck, to whom your queries have been sent, says:—"The eyes of Vines for growing in pots for fruiting in January, February, and March, ought to be struck in January or beginning of February, and the eyes should be taken from well-ripened wood from an early Vinery. They must be started in a brisk bottom-heat and grown in it, as well as shifted and stopped two or three times till they get strength and size enough by the time they are fit for the last shift into fruiting-pots. This is for young pot Vines intended to be forced the year after being struck. There is less attention required in raising early pot Vines, by growing them the first year as strongly as possible, and then cutting them down to have a strong rod the second year for the next year's forcing. They may, in the second year, be shifted into the largest-sized fruiting-pots, and each Vine will then bear from twelve to fourteen bunches of finely-coloured fruit; at least I had this year, on pot Vines so managed, that quantity of bunches on the Esperione

Hamburgh and Foster's White Seedling. The greatest cause of success in forcing early pot Vines is in having the wood well ripened as early as possible, and then placing them in the open air in the latter end of the summer and autumn to harden the wood into a state of rest before being forced. As a black early Grape for growing in pots there is no better and surer bearer than the Hamburgh, and I prefer the variety of it named the Esperione for the purpose. The purple Constantia or Frontignan is another excellent variety for early forcing, and, having a perfumed flavour, it is much preferred by some. As to white Grapes for early pot culture I have found Foster's White Seedling, Buckland Sweetwater, and the Royal Muscadine to be the best."]

MERAN AND THE "GRAPE-CURE."

MERAN, the ancient capital of the Tyrol, though it has long ceded its metropolitan honours to Innsbruck, remains the head-quarters of the Grape-cure, and is unrivalled for beauty of situation and charm of climate. Rounding the shoulder of a mountain, one comes suddenly on a scene of peace and of luxuriant beauty which might belie a vale of Arcadia. Mountains of 6,000 or 7,000 feet high enclose a wide valley, dotted with farmsteads and white cottages, all surrounded by a southern vegetation. Here grow magnificent Spanish Chestnut and Fig trees, while a perfect net-work of Vines trained over trellises covers the hills. Along the edge of the road grow immense Pumpkins, with their robust picturesque leaves and yellow flowers gazing right in the sun's eye; while beyond lie fields of Indian Corn—making up altogether a rich and luxuriant picture. After a couple of miles of this scenery we entered Meran, a sunny cheerful town, lying on the right bank of the bright and brawling little river Passer. The population of Meran numbers 4,500; this is greatly increased during the months of August, September, and October, by strangers, who come for the Grape-cure, and to rest awhile in a climate so dry and warm, and yet so much cooler than Italy during this season. The visitors are chiefly those suffering from chest complaints. The Meranees are not an enterprising people, and trust confidently to the beauty of their town and climate, and most implicitly to their Grapes, to allure the stranger. And there is a charm in this simplicity far more delightful to many than the usual stereotyped amusements of a watering-place. A band plays every morning in the gardens; and here the visitors walk, eating Grapes, or read, or sketch with a basket of Grapes beside them, or ramble about in family groups—all, and always, eating Grapes. The first thing one does on arriving at Meran is to buy a basket; Grapes of the richest bloom and most delicious flavour are to be seen all around; they hang in purple bunches over all the hills, in every garden, round every cottage porch; carts and baskets full of them are brought into the town every morning, and they lie heaped on stalls in glorious profusion at the corners of the streets. Everybody who comes "takes the Grape-cure," to the extent of eating more Grapes than he ever did before in his life, unless he prefers Pigs, which are almost as plentiful and excellent. No quantity of Grapes under three pounds a day can be considered as a true and energetic Grape-cure. The patient begins with one or two pounds a day, dividing the quantity into three portions—one taken an hour before breakfast, the next between that and dinner (which takes place at 12.30 or 1 at latest at Meran), and the last portion in the afternoon or evening, an hour before the last meal of the day. The Grapes must be eaten in the open air, an injunction obeyed to the letter at Meran, as everybody walks about eating Grapes all day long, unless you prefer taking one of your three portions sitting in your verandah, gazing out over the lovely country. After a couple of days the quantity is to be increased by half a pound, until it reaches three or four pounds. This is often sufficient—dependent, of course, upon the nature of the disease, the progress it has made, &c. Many people eat six pounds daily, although as many as eight is said to be unusual. Patients are not to be discouraged if they feel less well after three or four days of Grape eating; this is not seldom the case; but, this crisis being past, they speedily feel the benefit of the treatment. One great advantage of the Grape-cure is that no special diet is enforced. Food in any way trying to the digestion is, of course, forbidden; and other fruit is in general not recommended; but, after eating from four to six pounds of Grapes daily, one does not feel any particular inclination for further indulgence in Pomona's bounties. Grapes, containing a large quantity of nourishment, have a very satisfying effect on the appetite generally, and less of other food is required; and, in cases where the cure is taking good effect, the patient gains in weight, and, after a while, in strength also. The cure occupies from four to six weeks, and during September and October the Grapes are at their best. Early ones are to be obtained in August and late ones in November, but they are neither so good

nor so efficacious. The country, too, is in its greatest beauty during the height of the Grape season. Not but what April is a charming month at Meran, when the abundant Almond and Apricot trees are a mass of blossom, and when the traveller returning home after a winter passed in Italy is tempted to linger awhile in the pretty little town before proceeding northward.

GARDENING FOR THE WEEK, AND AMATEUR'S CALENDAR.

The Flower Garden and Pleasure Grounds.

THE time has almost arrived when, in ordinary seasons, the flower garden is expected to be at its best; but this is far from being the case this season, and if a decided change in the state of the weather does not take place soon the display this season will be meagre, as well as of short duration. Wherever watering the flower beds is attempted, it ought to be done effectually, otherwise it does more harm than good. There is frequently considerable difficulty in properly applying the water to the beds in very dry weather and on light soils, when and where it is most required. More particularly does this happen when such beds are on an incline, as, where that is the case, the water applied is almost sure to form channels for itself, and pass off, leaving the thirsty occupants of the beds little, if at all, benefited. The only remedy for this is mulching with some suitable material, as this prevents the water from running off the surface, as well as prevents, to a great extent, evaporation. But, as a mulching in the flower garden, manure is hardly admissible, on account of its untidy appearance; and, possibly one of the best materials for that purpose, where it can be conveniently obtained, is tanner's bark, or tan fresh from the tan-yard; this, when neatly applied, has by no means an untidy appearance, and possesses also the property of driving ants and other troublesome insects from the beds. The time is also at hand when steps must necessarily be taken to commence the propagation of plants for next year's embellishment, but, to attempt at present to take cuttings from *Pelargoniums* and other plants occupying the flower beds, is of course out of the question, as, in most instances, such plants have hardly as yet made a start. The desirability, therefore, of possessing a well-stocked reserve garden, such as has formerly been recommended, will now be admitted. Now is, however, a good time to make a rough sketch or plan of the flower garden, and on each bed and border of which to write in pencil the name, or names, of the plants intended to be used in planting it next season, and also the probable number of plants likely to be required for such a purpose. By an occasional reference to this sketch, thus arranged, it will be seen at a glance what amount of stock is required for each particular department, and the annoyance of having too few, or of having more of some varieties of plants than are really required, may be easily avoided. Now is also a suitable time to take a careful survey of the present arrangement of the parterres; and, should any improvement or alteration suggest itself as regards the distribution of colours, or other matters, a note should be made of it, to which reference may be made hereafter. The hot and dry weather is anything but favourable to Roses, the summer blooms of which will soon be over. Remove at once, therefore, all dead and decaying blooms, water frequently, and mulch the plants, encouraging them in every possible way, with a view to induce them to produce an abundance of autumnal blossoms. Stake and continue to tie up, as may be required, *Dahlias* and *Hollyhocks*; copious watering is indispensable as regards the latter, otherwise red spider will be sure to attack them. Castor Oils of different sorts, *Wigan-dias*, and various other sub-tropical plants, should now be neatly supported by means of stakes, if this has not already been done; and beds of such plants should be abundantly supplied with water. Follow up the layering of *Carnations*, *Cloves*, and *Picotees*, as formerly directed; and be careful to, in some way, prevent birds from scraping the soil from them during dry weather. Where Pink pipings have been inserted under hand-glasses, and are now fairly rooted, the glasses may be removed, and the first opportunity should be taken, after a good rain, to plant them where they are intended to flower. *Anriculas* may now be potted; some prefer to pot them before July is out; others defer that operation till August. It is a rule with cultivators to keep their plants dry and comparatively dormant during June and July. Water is almost entirely or quite withheld; the plants may be said to be maturing their growth. One well-known grower is fond of asserting that, years ago, he found out the benefit of potting early; and he asserts that many who have taken his advice on the matter can testify to its usefulness. He says, "If the plants are neglected till the middle or latter end of August, the old mould gets dry and finished up, the plants suffer, the fresh fibrous

roots, which they ought now to be pushing, die off in consequence; while, if potted early, while vegetation is going on, the new, fresh, and wholesome soil encourages and stimulates, as it were, new life into the plants." In re-potting, a good mellow, sandy loam, either yellow or black, must be had. Some like that kind of black turfy loam found in the moors of Lancashire and Yorkshire; and in this will be found a certain amount of a kind of silvery sand, which is considered to be preferable to any sea for fine silver sand found in the south of England. Besides the sand found in the black loam, some river-sand is added. In the south, where a fine yellow, but somewhat adhesive, loam is found, a quantity of sand and well-decayed cow-dung must be mixed with it; rough silver-sand is the best. On account of the prolonged drought little mowing will, at present, be required, but the lawn will, nevertheless, require constant attention as to sweeping up leaves and other littery matter, the dry weather having had the effect of making the leaves of deciduous trees, as well as of evergreen shrubs, fall in great quantities unusually early. Eradicate plantains and other weeds and coarse Grasses, from the lawns and Grass belts. There is little difficulty in discovering such intruders at the present time, as the finer Grasses are quite brown, and apparently dead; the first good rainfall will, however, make that all right.—P. GRIEVE, *Culford Gardens, Bury St. Edmunds.*

Roses.

In this month we must bind our Briars with those varieties which a keen and constant observation, at home and elsewhere, has taught us to admire the most. Ample instructions with cleverly-drawn illustrations, are given by writers on the Rose as to the art of budding; but an experienced gardener, with a sharp knife and a hank of thick cotton, somewhat resembling that used for lamps, will teach the amateur far more quickly and effectively than he can possibly be taught by books. Should mildew make its appearance, remove the leaves most affected, and cover the rest with flowers of sulphur when the tree is wet from shower or syringe, giving them another good washing next day. Mr. Rivers recommends soot as a remedy, and kindly sends me a letter, written Sept. 6, 1869, recording the result of a successful experiment. "Have you mildew?" he asks—"try soot. Some time towards the end of July a batch of Hybrid Perpetuals, five plants in pots, were white with mildew. Perry" (his late foreman) "tried sulphur without end, and at last in desperation smothered them with soot, in the dew of the morning. This rested on them for four or five days, and was then washed off. The effect was marvellous; the mildew disappeared, the leaves turned to a dark green, the buds opened freely, and the flowers were brilliant." That yellow-bellied abomination, the grub which produces the saw-fly, in this month attacks the Rose, sucking the sap from underneath the leaf, and changing the colour of the part on which he has fed from bright green to dirty brown. The process of "scrunching" is disagreeable, but it must be done. During the continuous droughts which frequently occur in July, it is desirable, of course, to water every evening, where water and waterers can be had in abundance. Elsewhere, I would advise that the surface of the beds be loosened from time to time with the hoe. It will thus retain for a much longer period the moisture of nocturnal dews. But there is nothing like a mulching of farmyard manure. Fading Roses should be removed from the tree, and preserved for the *pot-pourri* jar. The other flowers of the garden perish, but—

Sweet Roses do not so:—

Of their sweet deaths are sweeter odours made.

—S. REYNOLDS HOLE.

Hardy Flowers.

One of the chief operations in connection with hardy plants, at the present time, is that of collecting seeds, which on many early summer-blooming plants are now ripe; they should, therefore, be gathered and placed in a frame till thoroughly dry, when they may either be cleared of husks at once or stored as they are until a less busy time occurs, when they can have attention. In gathering seed, care should be taken to write a ticket or label for each species, or much confusion may arise at sowing time. Decaying blooms of perennials should be carefully removed, if not required for seeding purposes, as they tend to disfigure the appearances of the plants. Vigorous-growing sorts should be attended to as regards staking and tying, and some kinds, such as the *Gunnera scabra*, strong plants of *Pampas Grass*, &c., will be greatly benefited by thorough waterings, as will also flowering specimens of *Pentstemons*, *Phloxes*, &c. Cuttings of perennials may still be struck, and all seedlings of these ready for handling should be pricked off. Some Alpines in pots will be all the better for a top-dressing, and strong growing sorts should receive a shift into larger-sized pots than those in which they have been growing. Specimen plants in pots should receive attention as to watering, those which have bloomed requiring but occasional

applications in that way. Outdoor gardens continue gay with hardy border plants, some of which have been blooming for weeks in succession, notably such as *Corydalis lutea*, *Dicentra eximia*, *Snagdragous*, *Lathyruses*, *Geranium sanguineum*, *Erodium Manes-cavi*, various *Lilies*, &c. While, in addition to these, there are various others which have but recently come into flower; conspicuous among these are *Galega officinalis*, a tall plant of the Pea family, which bears an abundance of pinkish flowers; *Malva moschata alba*, a handsome white-flowering variety of our native Musk Mallow, thoroughly worthy of a position in any border of perennials; *Phloxis pungens*, a showy member of the Sage family, which produces large spikes of purplish-violet blooms, arranged in whorls; *Aster pyrenæus*, a neat and early-blooming species of this well-known genus; the old *Monarda didyma*, or Bee Balm, as it is commonly called, the bright scarlet flowers of which are bright and effective; and *Scolymus maculatus*, a Thistle-like plant about 4 feet high, surmounted by showy heads of orange-yellow flowers. Several of the *Aselepiases* have also commenced to bloom, and the *Santolinas*, so useful for edgings and other purposes in the flower garden, are highly ornamental when established tufts are seen studded with pretty button-shaped flower heads, as they now are in many places. The blooms of several hardy aquatics are now very striking, particularly those of the native-flowering Rush (*Batium umbellatus*), *Justicia peduncularis*, and *Pontederia cordata*.—T. SPANSWICK.

Indoor Plant Department.

The deficiency of blooming plants in conservatories at present may be compensated by a liberal admixture of such fine foliaged plants as *Dracænas* and *Colens*. Of the former take such kinds as *Cooperi*, *ferrea*, and *terminalis*; the bright colors of their leaves will supply the place of flowers, and the plants will not receive injury for the next two months by being placed in a cool house; neither will they suffer so much as flowering plants would by standing somewhat closely together, the greater amount of air and lower temperature of the house, compared with the stove in which they have been grown, having the effect of stopping them from making much growth. The different varieties of *Colens* should be placed so as to get as much light as possible, otherwise they become drawn and have an unsightly appearance. The old *Plumbago capensis* is another useful plant at this season, and the present is a good time to propagate it. The small half-ripe side shoots will strike freely inserted in small pots under bell-glasses in a little heat. These, when struck, should be encouraged to make growth before the autumn gets too far advanced. They should be wintered in a temperature of 45° or 50°. In the spring they should be headed down and potted in 6-inch or 8-inch pots, using good fibrous loam. If desired, some may be grown on in larger pots, but for general decoration they are more useful in a comparatively small state. The plants will last for years by cutting them back in the spring just before they commence growth and when they have broken, removing a portion of the old soil, which should be replaced by new material, re-potting them in the same or a size larger pot. *Fuchsias* should have their seed-pods picked off regularly, or they soon cease to flower freely; they ought to be supplied twice a week with weak manure-water. Double *Petunias* are very useful at this season, either as decorative plants or for furnishing cut flowers. These should receive regular attention in the way of stopping and tying, to induce them to break back, or, from their quick somewhat straggling habit of growth, they become unsightly. *Lilium auratum* is a most useful subject for conservatory decoration at this season, but should not be introduced in too great numbers at a time, as its perfume, being so powerful, is oppressive. Attend well to the different varieties of *Lilium lancifolium*, by keeping them neatly tied out, and supplying them regularly two or three times a week with manure-water, otherwise the soil becomes exhausted, and they lose their bottom leaves, which destroys half the beauty of the plants. They must on no account be allowed, at this season especially, to suffer from want of water, even for ever so short a time, or the same mishap will follow. *Chrysanthemums* should now or soon receive their final shift, using from 8 to 10 or 12-inch pots, according to the size the plants are required to grow; 10-inch is a useful size. After the roots have got fairly hold of the soil in the blooming-pots, they should receive strong manure-water every other time they are watered. They will bear it as strong as any plant in cultivation. The Mashroom-shaped style of training is the most in favour with those who grow *Chrysanthemums* for exhibition, but it is unnatural and unsuitable for general decorative purposes. Plants of the larger varieties, confined to from two to five shoots each, neatly tied to a stick, the head of the plant brought out to about twice or thrice the diameter of the pots they occupy, will be found the most useful, and this will give them ample room for the development of their foliage, which, if they are well grown, will be of the darkest green. As the shoots of the large kinds branch out in growth, they should be thinned to the number of

flowers the plants are intended to carry, leaving one flower to each shoot. The plants will carry from six to eighteen, according to their strength. To those who have not tried this thinning process, it may appear a great sacrifice in quantity; but either for cutting or for decoration on the plant, one good flower is worth three inferior ones; and flowers so treated will last fresh on the plant fully a third longer than others that have been insufficiently thinned. The *Pompones* also require thinning, but not so much as the large varieties, neither in the reduction of the number of shoots nor to the number of flowers each shoot will carry; these may be left from three to half a dozen to each terminal shoot. The first batch of *Cinerarias* should now or soon be in their flowering pots, 6-inch ones, and should be encouraged by watering once or twice a week with manure-water; shade slightly in the sunny part of the day, and keep them quite clean from aphides. *Primulas* should be similarly treated, with the exception of keeping them a little drier at the root. Strike more cuttings of *Hydrangeas*, for succession. Attend well to *Euphorbias*, *Poinsettias*, *Salvias*, *Bouvardias*, and things in general for winter blooming. Press of other work frequently causes these things to be somewhat neglected, but in the case of quick-growing plants of this description, neglect is fatal to their flowering satisfactorily when the time comes that they are required.

Orchids.

Imported *Odontoglossums*, *Oncidiums*, and *Cattleyas*, that have made some progress on benches of *Sphagnum*, may now be potted either singly or two or three plants together in a pot; the former method is, however, the best. Use small pots at least half full of crocks for drainage. Both crocks and pots should be well washed and perfectly dry when used. The compost best suited to these plants is one of a free open description, through which all superfluous water readily passes away. Pull the peat into pieces the size of pigeons' eggs, rejecting all refuse, grass-roots, and small dust, which, if used, washes down into the drainage, and soon causes the soil to become stagnant and sour. The peat should be mixed with living *Sphagnum Moss*, crocks, or charcoal, and sufficient coarse grit or sand to keep it from becoming firmly bedded together. Place a layer of Moss over the crocks before filling the pot with compost, as this causes the drainage to last perfect for a much longer period. After potting, surface the pots with living Moss, and set the plants in a shady corner of the house until they establish themselves. Small pots are much better than large ones for nearly all kinds of Orchids, and it is a good plan after the plants become too large to place the plant, pot and all, into one a size or two larger, merely filling up the spaces with *Sphagnum*. This is a far better plan than turning the plant out of the pot, for, if well established, the best roots will cling to the sides of the pot so firmly as to render it impossible to separate them without injury. Orchids now in flower, as *Cypripediums*, *Odontoglossums*, *Oncidiums*, *Miltonias*, and *Masdevallias*, may either be removed to the conservatory or sitting-room, where their blossoms will last as long, or even longer, than when kept in the houses. Damping down two or three times daily and shading must be strictly attended to, as otherwise much injury may result, especially to the cool growing species.—F. W. BURIDGE.

Indoor Fruit Department.

As soon as the fruit in the Pine-stove has been well ripened and cut, the first opportunity should be taken to clear out and thoroughly cleanse the compartment by washing the glass, woodwork, and walls with water. Then prepare some boiling water, with which incorporate newly-burned lime, sulphur vivum, and some fresh soot, and with this mixture give the walls, flues, and all corners a good washing twice, so as to fill up every crevice. The woodwork should also be painted over with good old white lead mixed with boiled oil. After this all will become sweet, wholesome, and water-tight for some time to come. See to joints of the pipes, and examine and cleanse out both pipes and boiler. See also to the flues, fireplace, and bars, and have all properly adjusted and in good working order. If the houses are heated only by flues, examine and clean them thoroughly, and wash them over twice, as above directed, in order to have all crevices stopped and in good working condition. Renovate and renew all plunging materials, and lose no time in filling up again with fruiting plants that are about to start for autumn and winter use. Encourage succession plants in every stage to make vigorous sturdy growth by a kindly bottom-heat, applications of good clear tepid manure-water at the root, and heavy applications of clear soot-water from the engine or syringe, early in the afternoon, should be given, and air applied freely night and day. Suckers, of course, should be taken off as fast as the fruit is cut, with a piece of the old stem adhering to them, which assists holding them firmly in their pots, supporting them without a check till rooted, which they will do in a very short time on a kindly bottom-heat, and grow on without loss of time. Unless suckers are constantly potted on as

they become ready at all seasons of the year, there must be a lack of fine-seasoned well-prepared fruiting plants ready for every day in the year, to fill at once the places of those removed. Respecting the choice of suckers, discard those of plants that produced a number of them, and also those from plants that did not produce a first-class perfect fruit. As regards Vineries, give the earliest house all the air possible as soon as the wood is well ripened, so as to bring the Vines into a state of rest. The earliest pot Vines will now have their canes well browned and ripened, and may be placed in the open air. If heavy rains occur later in the season, the pots may be placed on their sides, so that the roots may not get drenched too much, before they are placed in the pits or houses for early forcing. Peach and Nectarine trees in the late houses will now require every possible assistance to ripen the fruits perfectly, by exposing them to the direct influence of the sun and air. When the fruits are all gathered, the foliage must be kept clean and healthy by repeated syringings; sometimes brown scale puts in an appearance, but it must be eradicated as soon as detected. If the borders are dry after the crop is off, a good soaking of manure-water will greatly assist the trees in ripening their buds. In orchard-houses, syringings must be discontinued as soon as the fruit begins to ripen, and only as much water given to the roots as will prevent the trees from suffering. All the air possible must be given, and in very hot days damping the floors and stages will do something to save watering and keep the air healthier for the trees. Keep pinching all strong-growing shoots, on purpose to encourage strength in the weaker ones, and to keep the trees in form. The latest put out Melons will now want a little manure-water to force them on, and if they are grown in pits the surface of the bed may be mulched, to prevent the sun from drying the soil too much. The laterals will want frequent thinning and regulating, and a healthy foliage encouraged, for upon this is the flavour dependent. Late Cucumbers in frames will now want nearly daily attention in the way of stopping each shoot after the fruit is set, and placing them on a piece of slate or glass.

Hardy Fruit.

Continue to train and nail in all the young wood needed on wall trees, also to wash the trees; that is a better way and more effective than sprinkling overhead in the afternoon of bright days until the fruit is almost ripe. Washing cools, refreshes, and invigorates the leaves and branches, and also adds to the size and quality of the fruit. Few things are also more effectual in preserving the trees from insects. Water in copious streams is obnoxious to aphides; it forces them to relinquish their hold and sends them in showers to the ground. It is also the greatest foe to red spider, and even mildew is quite as often the result of drought, as of an excess of moisture. If dry sulphur is dusted on the wet leaves, mildew will be subdued, rather than aggravated, by a good washing from the garden engine. Should it, however, attack the fruit it must be instantly dusted either with dry sulphur or half and half sulphur and slaked lime. If dull weather ensues, then overhead washings must at once cease. Vines on walls should be stopped, and the leading shoots carefully trained and placed in the best positions. Vines in the open air were in flower this year by the 15th of June; as a rule, they are seldom in flower till the middle of July. It is safest not to stop the shoots of outdoor Vines too early, the more top-growth the greater the activity of the roots. The growth of the laterals stimulates to the full the energy of root-force, and when stopped, that energy is concentrated in the bunches, and they are carried through the flowering and fruit-swelling period with a rush. Besides the leaves are most useful for protection in a season like the present. Outdoor Grapes do well in many of the southern and eastern counties, and it is somewhat surprising that they are so little grown in gardens. Grapes are grown on many cottages, that would be relished at the tables of the rich. Further, outdoor Grapes, if thinned in bunch and berry, really swell to the size of the same varieties grown under glass, in favourable seasons; whereas, many of the evils, such as shanking, so prevalent under glass, are wholly unknown on the open wall. This is notoriously the case with that most exquisitely flavoured of all Grapes, the Frontignan, which so many cultivators have left off growing on account of its double tendency to shank and shrivel. In favourable positions out of doors it does neither, while the flavour is equally luscious with those grown under glass. As soon as the fruit is fairly set let those intended for table be thinned; possibly, it will also pay to thin those intended for wine, for it seems to be forgotten that wine, in respect to its quantity and quality, is a matter of Grape juice, not of Grape rinds and Grape seed. It is also almost certain that the larger the berry the better and richer the quality of the expressed juice. The bunches of Grapes intended for wine should likewise be thinned down to a reasonable crop as well as the berries, and this in the interest of the Vine as well as the quality of the wine.—D. T. FISH.

The Kitchen Garden.

We have scarcely had sufficient rain since the 2nd of June in this district to lay the dust on the roads, whilst a succession of bright sunny days has made the earth as hot as a furnace, rendering kitchen gardening by no means an easy task. Those who had the means and took the precaution to carry out persistently mulching and shading, will be able to appreciate its beneficial influence upon their crops, as well as its value in saving labour in watering; in fact, watering now on the bare earth unless the land can be flooded is of little use. Many kinds of vegetables now come on so rapidly as to make it difficult to keep up the necessary succession; great care should, therefore, be used in gathering Peas and French Beans, never to allow any of the pods to get too old for use; this has an exhausting influence upon the plants, tends to restrict production, and to shorten the period of bearing; when gathering the crops, also avoid, as far as possible, injuring either leaves or stems. Late Broccoli and winter Greens may still be planted whenever a favourable opportunity occurs, and the sooner all such crops are in now, the better in order to get the growth firmly built up before winter. Globe Artichokes should be heavily mulched with manure, if not already done, and immediately afterwards should receive a good soaking of water, the production of good heads later in the season will be much assisted thereby, and also by the removal of all bare stems from which heads have been already cut. Successional sowings of Lettuce, Endive, Radishes, and small salads should still be made under a north-wall, and, in order to ensure a rapid and continuous growth, shading even in such a position during the continuance of the present hot weather is indispensable, at least in the hottest part of the day. Cabbages that have been cut, and the stems of which are pushing again, should have all old leaves removed, the surface of the ground deeply loosened with a hoe, and top-dressed with manure; Cabbages are often cut and the stalks immediately afterwards dressed up, this is not, however, good practice; the check on the plants is too great, and it has a deteriorating effect upon future production. In all cases when Cabbages are cut the bottom leaves should remain on the stems till the sprouts have shot an inch or so, when they may be carefully cut off. All vacant spots from which winter Onions and other crops have been removed, should be manured and dug over in readiness for late Turnips, Spinach, &c. A season like the present will probably interfere with our calculations in timing the sowing of various crops, especially such as are required for next year's supply; and as the land, after such a roasting, will probably retain its heat longer than usual in the autumn, late growth may reasonably be anticipated. I should, therefore, recommend later successional sowings of Cabbages, Winter Onions, Spinach, Turnips, &c., than is usually found desirable.—E. HOBDAV.

Cottagers' Gardens.

No time should be lost in finishing the planting of all kinds of Winter Greens and Broccoli, also Leeks and Celery. A small sowing of Cabbage seeds should be made at once for spring use, and about ten days hence, for the general crop. Keep the soil frequently stirred amongst growing crops. Attention must also be paid to mulching and watering Beans, Peas, Vegetable Marrows, &c., as, if they are left until nearly withered and the earliest bloom lost, there will be little to repay the labour. The earliest varieties of Potatoes, now fast approaching maturity, may be lifted and stored at once; those intended for seed should be fully exposed to the air for some time. This is the best season for propagating Geraniums, for, with but ordinary care, one can scarcely fail in striking them at this season, and in getting them well established before winter. Attend to the tying up of Dahlias and such plants as require support. Pot plants should receive some stimulant in the shape of diluted manure-water, in order to induce them to prolong their season of blooming.—J. GROOM.

OBITUARY.

WE have to announce, with much regret, the death of Mr. Robert Godfrey, late partner in the firm of Waterer & Godfrey, Knaphill. He had been at the Midland Counties flower and fruit show at Birmingham, and had returned to his residence near Ryde, Isle of Wight. On Sunday night last he retired to his bed complaining of slight indisposition, and at three o'clock on Monday morning he was found dead. He was supposed to have had a slight sunstroke, brought on by the fatigue of travelling and the late excessive heat. He had retired some years from the business, with which he was connected for over forty years; he was an ardent lover of his profession, and by his indefatigable assiduity and shrewd business qualities in conjunction with Mr. Anthony Waterer—the present sole proprietor of the establishment—he developed the resources of Knaphill nursery in such a manner as to make it one of the best, if not the best, hardy tree and shrub nursery in existence. He was about sixty-two years of age; frank and generous in disposition, and has left a wide circle of friends to lament his loss.

THE GARDEN.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

STRAWBERRY PLANTATIONS.

Of all our hardy fruits, none is so much influenced by soil as the Strawberry. Strawberry plantations may be made as soon as suitable runners can be obtained for the purpose: but where one sort will grow and fruit well, another will not only bear indifferently, but the plants absolutely die. All cultivators, however, agree as to Strawberries enjoying a strong heavy soil; such, undoubtedly, is the case, and it is rarely that growers for sale attempt their cultivation in large quantities where this condition of the land does not exist. There are, however, some thousands of gentlemen's gardeners who have often to deal with land of a totally different description; and who, nevertheless, are expected to furnish good Strawberries. In dealing with unsuitable soils, the usual method of planting in rows 3 feet apart, and something like 2 feet asunder in the row, is anything but conducive to success. In very light soils numbers of the plants get half thrown out of the ground in the winter during alternate frost and thaw, dying or making little progress in the spring; and by their being thinly planted they cannot be spared without serious blanks, the evil being much increased by the numbers that died off suddenly during the hot and dry summer weather. Again, the crop produced the first season from this thin system of planting, even if every plant bears, is very small as compared with closer planting. On naturally light dry soils, I put the plants in 4 feet beds, 1 foot asunder every way. If a few of these get thrown out by frost during the winter, they are not so much missed as if they had been planted far apart. The same holds good in respect to any that may go off in the heat of summer; but the leaves prevent the action of the sun on their roots to a much greater extent than the best mulchings that can be applied without the aid of the leaves. There is no better crop to precede Strawberries than early Potatoes, after which the ground will be much benefited by being deeply dug, working into the bottom a heavy dressing of cow or pig manure, which, being of a cold nature, is much better than stable dung. Before planting, tread the ground firmly, as is done in the case of Onions sown in spring. The plants should be got in as early as rooted runners can be obtained; and, if a crop is expected the ensuing season, they should not be planted later than the middle of August. Unless copious rains fall at the time of planting, they must be thoroughly soaked by means of the watering-pot, and not allowed to get dry until they are well rooted and growing freely. They will be greatly assisted if, as soon as planted, they are covered with Pea-sticks, over which should be thrown mats or some similar covering, during sunny weather, for a fortnight or so, after which time, if the weather is moist, or they have been supplied with sufficient water, they will be fairly established. Nothing more need be done through the autumn, except keeping all runners removed and the ground hand-weeded, all hoeing having a tendency to make the soil, naturally too light, still lighter. In the spring, give a moderate mulching with short littery dung; this requires to be carefully done by hand, the distance between the plants not admitting the use of the fork. The fruit the first season is usually the finest the plants produce, and, from the great number of plants that occupy the ground, they generally yield a good crop. After it is gathered, and a sufficient number of runners secured for planting, the centre row in each bed is cut clean out, and all remaining runners removed through the autumn. If this is properly attended to, the plants will bear a very great weight of fruit the second season. Unless there is a bad prospect of runners in time for planting sufficiently early, or the beds are more than ordinarily promising, as soon as the crop is gathered this second season they should be dug in with a dressing of manure, and the ground sown with Turnips. In soils unsuited to Strawberry culture two, or at most, three seasons is as long as they can be profitably kept, as, after that time, the plants begin to die off. On light land the plants must be well

watered, both during the time the fruit is swelling and also after it has been gathered. This last watering is of the greatest importance, for if, after the plants have ripened off the crop, they are too dry to commence growing until late in the summer, they will not have time to ripen the growth made, and the result will be large barren crowns in the spring. If the extent of ground to be planted is greater than the means at command for shading or properly attending to it with water until the plants have got established, still there should be no delay; as soon as the runners are ready they should be planted in a nursery bed, 4 or 5 inches asunder each way. In the limited space they will occupy here they can easily receive the necessary attention, and they can be removed a few weeks later, with good balls, to the beds where they are to fruit. As this system of culture is more calculated to excite growth in the plants than the treatment usually recommended for good Strawberry soils, owing to the heavy manuring and liberal use of water, such sorts should be selected as are free bearers, and not too prone to make an over-abundance of leaves. British Queen is generally too tender for such soils; and each grower will do well to ascertain the sorts that do the best in his immediate locality. In treating upon Strawberry culture, reference is usually made only to the nature of the surface-soil; little regard is paid to the sub-soil, a matter of no small importance. Heavy strong land, such as Strawberries like, is generally found resting on a sub-stratum of clay, and if at all wet, as such ground usually is, for successful Strawberry culture it requires more draining than is necessary for most crops. The land best suited for Strawberries is that where 15 or 18 inches of good strong retentive loam rests upon a gravelly sub-soil in a high situation. On land of this description they succeed in a way that has no equal. The crowns get thoroughly ripened in the autumn, and they escape frosts, even in such springs as the last, when those grown on lower land are in a great measure destroyed. Growers for Covent Garden Market, whose grounds are on the south of Enfield Chase, where the land is of such a nature as that just described, have had a wonderfully good season. The weight of crop has been excessive, and the individual fruit large, notwithstanding the extraordinarily dry season. A writer on Strawberry culture in a contemporary recently advocated their being grown in low-lying situations, forgetting that in such places, above all others, they suffer from two causes—insufficient ripening of the crowns in autumn, and through the bloom being cut off by frost in spring—conditions at once fatal to success, especially the latter, by which the earliest flowers, which produce the largest and highest-priced fruit, are so often destroyed. The sorts principally grown for market, in the neighbourhood just named, are President, Sir Harry, and British Queen, the same plants often standing and bearing well for eight or ten years. The land, previously pasture or meadow, is dug or trench-ploughed in the autumn, and allowed to lay through the winter. A crop of early Potatoes, or something similar that will be off the ground sufficiently early, is taken, after which the runners, as soon as they can be got and the weather moist, are planted in rows a yard apart, some 2 feet being allowed between the plants in the rows; but in dry seasons, and especially where the rainfall is usually below the average, it is often late in the season before there is sufficient rain to admit of permanent planting. In that case the plants have not time to get established before winter, and they bear little or nothing the following season. Strawberries in market gardens are well mulched in spring with the best fresh stable dung, litter, and droppings, used all together, the rains washing the manurial particles down to the roots, leaving the straw clean and in a fit state to preserve the fruit from being splashed with heavy showers. The ground is dug over between the rows in the autumn deeper than what would be considered by the generality of gardeners to be proper; but the nature of the land is such that it gets so excessively hard with being trampled upon in gathering, that no impression can afterwards be made upon it with the hoe until dug; and, although some of the roots must necessarily get destroyed by the digging, still, with Strawberries, as with other things, where the land is of a character well suited for their growth, they will bear, with impunity, treatment that would do serious injury in soils less favourable for their culture.

T. BAINES.

NOTES OF THE WEEK.

— WE have recently begun to experience a sort of vegetable famine in London, a dearth sure to come to us every season that brings with it a spell of hot weather in summer. Vegetables have been very scarce of late, and Cabbage, the most important of our green vegetables, dearer in Covent Garden than it has been for years; all this comes from having no provision for watering in our market gardens. The climate is supposed to be so moist that no artificial watering is necessary, and hence, when we have a dry season, London begins to starve for green food. No such state of things exists in any Continental capital. When our vegetables are inedible from drought, or perhaps not obtainable at all, the vegetables and saladings in Continental markets are as fresh and as tender as in the most genial month of May. Everything in the way of vegetables, except Potatoes, is getting dear; French Beans and Scarlet Runners, which last year at this time were obtainable at a penny a pound, were fetching eightpence a pound last week in Covent Garden Market.

— IN our recent article on shade-trees, we omitted to do justice to Catalpa syriacaefolia, which, as we write, is in great beauty in London gardens. There is a good specimen before Mr. Whyte's house in Devonshire Place North, and there are many specimens in and about London. The Catalpa has the prime qualities for a town shade-tree, viz., fine foliage, which does not drop off at the very season when it is required, but endures fresh on the tree as long as shade is wanted; beautiful flowers, freely produced, and a size and habit which suit exactly the town planter's wants.

— MR. J. P. QUIN, the well-known New Jersey fruit-grower, is now in England, and has brought to our notice some of those excellent Cranberries which are grown so extensively in the reclaimed swamp-lands of New Jersey. These berries are, as is well known, the fruit of *Vaccinium macrocarpum*, a plant which thrives perfectly in this country in peat soil, and one which has been grown in a few private gardens for its fruit. In New Jersey, however, it is the source of a very important trade, and now the fruits are beginning to be imported to this country. They travel well in barrels, and they are also sent over in capital condition preserved in cans. This is the form in which Mr. Quin has brought them to us, and they certainly seem to be a most agreeable preserve, free from excess of sugar, and having a peculiarly grateful slightly acidulated flavour.

— COVENT GARDEN MARKET is now well worth a visit from all interested in choice flowers and fruit. Imported Jargonelles, Bon Chretien, and other Pears are coming in rapidly from the South of France and the Channel Islands; as are also Reine Claude Plums, the best of the latter being tinted with purple on the sunny side after the manner of our Transparent Gage. These are packed tightly in neat boxes ornamented with lace or gold-edged paper. Large quantities of foreign Tomatoes continue to arrive from Lisbon packed in boxes of sawdust; these are, for the most part, poor both in colour and flavour, a circumstance, doubtless, attributable to their being cut and packed before they are fully ripe. Imported St. Michael Pines are now abundant and cheap, and, although scarcely fit for table, make a capital conserve, or, when candied, form a valuable addition to the winter dessert.

— FROM the reports of the fruit crops which we published last week and which we continue in our present issue, it will be seen that though early in the season the promise of abundant crops was great, the result in many places has not fulfilled our expectations. This is not to be wondered at when it is remembered that in May and in the early part of June we had hard and continuous frost, and bitter easterly winds. Everything, too, has suffered from want of water, and blight and insects have been usually abundant. Peaches and Nectarines on open walls have done well but in few places, and the same may be said of Apricots, which have done better on north walls this season than on any other aspect. As regards spring protection, Mr. Knight, of Floors Castle, prefers branches of Silver Fir to any other kind of covering, except indeed it be an evergreen coping of Ivy which he is leading from an east aspect, on which it grows, over a west one on which he has his Apricots. Ivy where it exists on outside walls might doubtless often be used with advantage in this way. The Apple crop is by no means good anywhere, and in some places it is quite a failure. In Scotland, however, it seems to be rather better than in England. Pears and Plums are nearly everywhere fair crops, except perhaps Damsons, which are variable. Rivers' Early Prolific appears to have succeeded in some places where other sorts have failed. Cherries are plentiful but small; Morellos grown in the form of dwarf bushes, are said to bear better, and to be less subject to insects than trees trained on north walls. What are termed bush fruits are abundant. Walnuts and other Nuts are in general scarce. Where heavy mulchings of dung have been applied the greatest possible benefit has been derived from them, keeping, as

they have done this roasting season, the ground cool, and, comparatively speaking, moist.

— WE regret to find the truth of our note, p. 20, Vol. VI., with regard to the disposal of the Drapers' Company's garden for building purposes, confirmed, and have this week, in another column, alluded more fully to the subject, with the view of directing public attention to it. The corporation of the City of London will, surely, not allow this fine open space to be built on.

— AMONG plants now to be seen on Messrs. Hooper's stand in Covent Garden, may be mentioned *Bravoa geminiflora*, a graceful Anaryllid from Mexico, which has long tuberous roots, fresh green linear lance-shaped leaves, and a slender spike of curved tubular orange-scarlet flowers, which remind one of the inflorescence of *Chelone barbata*. It evidently succeeds well treated as a half-hardy pot plant, and deserves to be more generally seen in cultivation than it is.

— WE learn from Mr. Noble that in the Sunningdale nursery there are four specimens of *Arundo conspicua*, the average heights of which are from 8 to 10 feet. They are bearing, respectively, thirty-two, forty-five, forty-nine, and sixty spikes of bloom, and the diameter of the plants is from 1 to 10 feet, while the spread of the flower-spikes is, on an average, from 1 to 14 feet. Three years ago, near the same spot, a plant of this beautiful hardy Reed might have been seen bearing no fewer than eighty feathery plumes.

— MR. HERBERT MILLINGTON writes from King Edward's School, Bromsgrove, that on the 24th ult., at 11 o'clock in the forenoon, a hailstorm of indescribable fury burst over a portion of that town. In a few minutes the ground was four or five inches deep in ice, much of which (twenty-four hours afterwards) was lying in thick white patches under north walls. Greenhouses were utterly wrecked; nearly fifty window-panes were broken in King Edward's School, and the garden was utterly destroyed. The strongest shrubs were materially damaged. Even Aloe had their thick leathery leaves pierced and shredded by the hail. The storm was confined to very narrow limits. Its area did not exceed 1,000 by 500 yards.

— MANY complaints have reached us as to the difficulty experienced this season in getting bedding plants established. This is a difficulty which Continental gardeners yearly experience, and which is overcome by them in a simple manner. After having been planted, the beds are mulched with well-rotted manure, leaf mould, tan, cocoa-nut fibre, or other material suitable for checking undue evaporation, and, in addition to this cool covering, *Selaginella hortensis*, *Tradescantia viridis*, and other dwarf carpeting plants, are freely used. Thus treated, and with liberal supplies of moisture, the plants make rapid progress, and we can confidently recommend the plan to those whom it may concern.

— THE destruction of Vineyards by Phylloxera, which has lately so much engaged the attention of entomologists and botanists, was recently, we learn from *Nature*, the subject of a bill in the French Assembly. Many prefects, on the plea of public welfare, have issued orders for the uprooting and burning of diseased plants, and opposing the introduction of foreign stocks; but to make this desperate course effectual, a special law putting the Phylloxera on a level with the rinderpest is necessary. M. Destreux has submitted a bill to make this possible and the Academy of Sciences gives it its support. Notwithstanding the investigations that have been made, no reliable specific against Phylloxera seems to have been yet discovered. The bill before the Assembly is received as "urgent."

— MR. BRAND's collection of Orchids and other plants was sold by Stevens the other day, and realised, as will be seen, fair prices, especially the splendid specimens of *Eucharis amazonica*, in the culture of which Mr. Howard is so famous. The following is a list of the prices realised by some of the finest specimens:—*Sobradia macrantha*, Woolley's variety, £3 3s.; *Phaltonopsis Schilleriana*, £5 15s.; a fine plant, do., £10 10s.; *Oncotoglossum pulchellum majus*, £10 10s.; *Cypripedium villosum*, £3 10s.; *Dendrobium densiflorum*, £1 5s.; *D. formosum giganteum*, £3 10s.; *Epidendrum vitellinum majus*, £5; *Dendrobium nobile caeruleum*, £9; *Aerides Fieldingii*, £5 10s.; *Vanda snavis*, Veitch's variety, £1 1s.; *Angraceum sesquipedale*, sixteen pairs of leaves, very fine variety, £18 18s.; *Coccyne cristata*, £3 15s.; *Anthurium Scherzerianum*, very fine plant, £15 15s.; *Adiantum Farleyense*, £1 15s.; *A. serotum*, £3 10s.; *Lapageria rosea*, a very fine plant, £7; *Camellia*, standard, double white, £1 15s.; *C. Princess Bacciochi*, £5; *C. imbricata*, £7 7s.; *C. Chandlerii elegans*, £3 10s.; *C. Valteraredo*, 10 feet high, one of the finest plants in the country, £13 13s.; *Dicksonia antarctica*, £9 9s.; pair of magnificent plants of *Seafortia elegans*, 10 feet high, £17 6s. 6d.; *Azalea indica alba*, £4; *Dracena Regina*, £5 5s.; *Eucharis amazonica*, splendid plants, from £5 to £16 16s.; *Bougainvillea glabra*, £3; *Cycas revoluta*, £5 10s.

NOTES FROM THE LEVANT.

(Continued from p. 72.)

I ARRIVED at Macri on March 24th, and, though the country had not suffered so much from snow as that about Smyrna, there had been a most unusual winter, all communication with the interior being still prevented by the deep snow on the mountain passes. The situation of Macri is very pretty, at the foot of the high range of mountains called Cragus in ancient times, but now Babadagh. Flat and marshy ground reaches for four or five miles to the north, where the valley is shut in by another range of mountains, the highest peaks of which exceed 7,000 feet. The first walk I took in the neighbourhood of the town showed me that the flora was very different from, and much richer than, that of Smyrna. A very tall-growing Spurge, *Euphorbia lycia*, with spikes of yellow flowers from 1 to 2 feet long, and *Asphodelus ramosus*, were the two most conspicuous plants. Anemones of many colours carpeted the ground, and many curious plants grow on the rocks which surround the harbour. Up a ravine, at the south end of the town, I found two very rare and beautiful plants, which I have succeeded in introducing to England, I believe for the first time. One, which has been named by Mr. Baker, *Fritillaria Forbesii*, resembles a good deal the *Tulipa* (*Fritillaria*) *Sibthorpiana* figured in the "Flora Græca," but has narrower leaves and a larger flower. Its pale yellow bells were peeping out from under the shade of bushes, among the roots of which, at a considerable depth, the small delicate bulb was growing in a light vegetable earth mixed with stones. The other plant was a most lovely Iris, of a pale but very bright blue, veined with white and yellow, and bearing its flowers singly on stems about 8 inches high, which are produced from tufts of narrow Grass-like leaves growing in large clumps. The tube of the flower in this plant is so long that the seed-pod, when formed, is close to the crown of the leaves. Notwithstanding this peculiarity and the distinctness of the foliage from that of all other Irises, the plant, though known previously to exist in Crete, Rhodes, Lycia, and Greece, has not been distinguished from *Iris stylosa*, of which it was considered by Boissier as a variety only. I found it abundant in many places in Lycia, especially near Macri, but never in the plains; elsewhere, it seems very indifferent to soil and situation, but grows finest in partially-shaded places, where some vegetable soil is mixed with the decomposed limestone of which the mountains are composed. Several pretty and curious Orchids were common near Macri, among them *Ophrys scolopax*, *Orchis papilionacea*, and *Peristylus densiflorus*; these, however, were not yet in full flower, and when I returned to Macri, three weeks later, I found them almost over. The common Pine of Lycia is *Pinus halpensis*, which is abundant on the mountains and grows in some places to a great size. Very little vegetation, however, is found under its shade, the soil and climate being too dry for any of the plants which usually grow in the Pine woods of more northern countries. The common Ferns about Macri were all of species which can endure great heat and drought, such as *Cheilanthes odora*, *Ceterach officinarum*, and *Nothochlæna lanuginosa*, the latter, which I only found on the rocks to the south-west of Macri, is a very curious Fern, covered with a dense woolly coating on the back of the fronds. It is found also in some parts of Italy, but is not, I think, in cultivation here. As I had some difficulty in getting horses at Macri, I was not able to leave till March 28th, when I started for Minara and Xanthus, at both of which places the remains of magnificent ancient cities exist. I found during my trip, what many others have no doubt experienced, that journeys of eight to ten hours a day on horseback do not give much opportunity for collecting plants, and as a good deal of my time was taken up with birds, and I was unable to carry more than a very limited supply of paper I did not preserve nearly so many plants as I ought to have done. As, however, Professor Forbes, who accompanied Admiral Spratt in his admirable survey of this country, made a large collection of plants, and has written an excellent chapter on the botany of Lycia in his work,* I will refer any who may wish to know more of them to that work. One of the most striking facts I observed, was that the herba-

ceous vegetation of this region, and of the Levant generally, is very much more in advance of the arboreal vegetation than in cooler climates. Here, in the month of April, spring flowers in the plains are almost over, and others, such as Poppies, Cistus, Veronicas, Orchids, Irises, are rapidly coming into bloom. The trees, however, are but little more advanced in leaf than they would be in Central Europe; Willows and Poplars were almost the only trees that had unfolded their leaves when I arrived, whilst Oaks had hardly begun to break their buds at the end of April. The reason of this, I believe, is that the spring, being much hotter and earlier than in Europe, rapidly brings forth all herbaceous plants; which are, by the time the more deeply-rooted trees are in leaf, already matured and beginning to die down. By the end of May, the heat and drought are so great that few herbaceous plants can resist it, and are completely burnt up by the sun. The trees, however, and such plants as *Salvias*, *Cistus*, and *Phlomis*, which grow on rocks and root very deeply into their crevices, find enough moisture to enable them to survive, whilst all kinds of bulbous plants are preserved by the strong soil, in which they mostly grow, until the autumn rain causes them to put forth new roots and begin to grow afresh. As far as I could learn, rain is almost unknown here during the months of June, July, and August, and the amount during March, April and May is very trifling. Cultivators of bulbous plants in England, and similar moist climates, should, therefore, remember that after the leaves of their plants have died down it is almost impossible to keep them too hot and dry, always provided the soil is strong enough to protect the bulbs from the air. I believe the great secret in growing such plants as *Iris susiana*, *iberica*, and some others from the same region which are reputed shy flowerers, is to put a light over them as soon as the leaves wither, and allow no rain to get to the roots. Experience, however, must be the best test of this, for though a good cultivator will always wish to know the natural conditions under which a plant grows he will not always attain the greatest success by imitating them. Large quantities of the Valonia Oak (*Quercus Agilops*) are found in the valley of the Xanthus, and many other parts of Asia Minor. The cup of its acorn forms one of the principal articles of trade, and is exported for tanning purposes to an enormous extent. Corn is also exported from Macri; but of fruit the country produces very little, though soil and climate are both all that can be desired. In no country that I have seen are agriculture and horticulture more neglected than in the south of Asia Minor. Except Onions, Garlic, and a few Lettuces, hardly any vegetables are grown, and though Tobacco, Cotton, and Vines, would be probably much more profitable than corn, I saw hardly anything but Wheat, Barley, and Maize. With a wooden plough of the most primitive description and a pair of undersized and half-starved bullocks, the Turk goes on scratching away at the surface of his splendid deep soil. He does not take the trouble to grub up any bushes which may be in his way, but hacks them down and ploughs round them. He then, careless of manure, and altogether ignoring the rotation of crops, crushes the clods by driving his cattle over the field attached to a beam on which he stands: casts his seed into the ground; wishes for rain, and trusts to "Kismet" for the result. When he has cut his crop he is not allowed to carry it until tithe has been taken by the authorities, who usually farm out this tax to corrupt and rapacious Greeks, and as the crop is generally mortgaged in advance, or sold at a low price to pay pressing claims, but little remains for the cultivator. The consequence of this is, that the peasants of Lycia, though apparently contented and comfortable, as far as their ideas of comfort go, are miserably poor. Hardly a village I entered had two-storied houses, and for the most part the only houses were one-roomed sheds, with a mud floor and earthen roof. Cattle are their chief source of wealth, but owing to the poverty of the pasture, the breed is a very inferior one; and the sheep, though perhaps well suited to the country, much more resemble goats in their shape than such sheep as we have in England. However, I am afraid that the agricultural condition of Asia Minor will not be of much interest to the readers of THE GARDEN, so I will continue my account of the plants. On ascending to about 3,000 feet in the Cragus Mountain, I found but little difference in the flora, except that the Pines

* "Travels in Lycia." Spratt and Forbes, 1852. Van Voorst, 2 vols.

were larger and the spring much more backward. Bulbous plants were more numerous, and Orchids much less so; but I did not find anything of much note in bloom, though a month later, I have no doubt, the hills would be covered with flowers. Both the *Fritillaria* and *Iris* I found at Macri ascend to an elevation of 3,000 feet or more, but other plants appear which do not grow lower down. The most beautiful were a *Cyclamen* with small bulbs, very much like, if not the same as *C. Coum*.* It was in full bloom and very beautiful. A fine large autumnal *Crocus* was in seed, and a *Tulip*, which, I think, is *T. Oculis solis* var. *lycia* (Baker), was appearing above ground. The excessively sharp and rugged nature of the rocks in these mountains made it very difficult to go off the paths which have been worn by the feet of goats and cattle during many centuries. Up to about 2,000 feet, I found another *Cyclamen* very abundant, which I take to be one of the numerous varieties of *hederifolium*, though leaves and bulb are very different. It has small and very brightly marked ivy-shaped leaves, produced on a stem sometimes several inches long, of which several are often borne by the same corm. The latter is irregular in shape and much rounder than that of the ordinary *hederifolium*, and never so large. These four sorts of *Cyclamen*, namely, *persicum*, *hederifolium* var. *græcum*, and the two above-mentioned, were all I saw in the Levant; but there is a species in the island of Cyprus which is said to be a very pretty thing; I believe that it is not known in cultivation at present, except in the celebrated garden of Herr Max Leichtlin, at Carlsruhe. Before crossing the Xanthus river we passed through a perfect jungle of *Oleander* and *Myrtle*, under the shade of which the pretty *Ophrys Speculum* and *O. fusca* were growing, and rode round the marshy plain to the hills on the other side. In three days riding, during which I crossed a pass of nearly 4,000 feet, I reached the valley of Cassabar, which is entirely shut in by high mountains, covered above 4,000 feet with a forest of *Pine*, *Cedar*, and *Juniper*. The most interesting plant I noticed during these days was *Linaria pilosa*, a charming little woolly-tufted plant, with bright golden flowers, which grows on the hot dry rocks near the coast. The valley of Cassabar is a perfect garden of Orchids, among which I found at least seven species and varieties of *Ophrys*, including *O. lutea*, *Speculum*, *insectifera*, *fusca*, *Tenoreana*; and as many more of *Orchis*, few of which, however, were yet in flower. The tubers of *Orchis longicornu* are collected by the natives for salep, a preparation which seems to have quite gone out of use in England. At Cassabar I also found the bright yellow *Romulea crocea* (Boiss.), which was just opening its *Crocus*-like flowers in wet places near the river. Leaving Cassabar, I passed by the gorge of Dembra to the coast, a route the beauties of which it is useless my attempting to describe. For eight or ten miles the river winds in a narrow gorge between cliffs of 3,000 feet or so in elevation; but, as, in its windings, it leaves no room for a road, it is necessary to ford it from thirty to forty times during the day's journey. By the sides of the stream many beautiful shrubs and trees grow—*Oleanders* forming a perfect thicket, and *Pines* of great size overhanging the water. Under their shade I found several plants which were not observed elsewhere, among them *Fritillaria lycia* (Boiss.), a fine tall species, something like *pyrenaica* in appearance, but having much more richly-marked flowers. *Ophrys ferrugineum* was also abundant—a species which excels in beauty all others I know, except, perhaps, some of the forms which are known as *Scelopax* or *Bertolonii*. It has a great swollen labellum of crimson velvet, reflexed at the edges, and marked in the centre with two dark blue shining specula, which resemble, in some measure, the shape of a horseshoe. I should recommend those who may wish to cultivate this or any of the *Ophrys* of the Mediterranean region, not to expose them to the wet and cold of our winters, for, even though they might stand the cold, their proper flowering season is so early in March and April that the beauty of their flowers would be destroyed by the cold winds and late frosts. I am informed by Mr. Needle, who grows these beautiful plants with great success, that they do far better if the tubers are placed against the side of the pot. In this gorge I also found the lovely *Thalictrum orientale*, with pure white delicate

flowers as large as a shilling; a fine plant called *Phaca botica*, and abundance of the same curious variety of *Cyclamen*, which grows on the Cragus Mountains. On arriving at Myra, on April 4th, I found summer really had come, the vegetation of the place being far in advance of any other I visited in Asia Minor. A great variety of curious and pretty plants covered the rocks and shore. Among them the most remarkable were *Passerina hirsuta*, which grew abundantly on the plain; *Phlomis fruticosa*, a Labiate plant, which though common in Lycia, here first showed its great yellow spikes of flower. *Aristolochia hirta* with its large gaping purple flowers; *Cynoglossum pictum*, and the pretty *Pisum fulvum*. Among the ruins of the ancient city and about its theatre, which remains in a very perfect state, were many rare plants, especially *Aloe vulgaris*, which I saw nowhere else, *Linaria pelissieriana* (?), *Ricinus communis*, and several kinds of *Onosma*, *Echium*, and *Borago*. At Myra, were several trees of a remarkable variety or monstrosity of *Fig*, which, instead of having a smooth bark as usual, had an immensely thick trunk covered with small branches and shoots from every part of the wood. In the ruins of a mosque was a fine old *Date Palm*, a tree which, though not often met with in Asia Minor, grows to a large size when planted in suitable situations.

The curious geological formation of the valley of Cassabar is very well observed on this route. The lower hills consist of a yellowish-white marl of tertiary formation, which probably once filled up the greater part of the valley, but being easily acted upon by the rain, has been washed down in a great measure, leaving a chaos of low sharp peaked and ridged hills, which run from the high mountain range, bounding the valley on the north-west. The soil of these hills is extremely barren, supporting only a scanty vegetation of stunted *Pines* and prickly shrubs, with *Cistus* and other herbs. At an elevation of 3,000 feet or so this marl disappears, and the mountains, like those of almost the whole of this part of Asia Minor, are composed of a hard white limestone or scaglia. As the road ascended, the trees became more numerous, until, at a height of about 5,000 feet, *Juniperus excelsa*, and *Cedrus libani*, were first observed, and though the snow had only been melted for a very few days and lay in patches on the shady places, a number of charming Alpine flowers were already in full beauty: *Cyclamen Coum*, or perhaps *cilicium*, was very numerous, and buried in flowers. Two species of *Crocus*, *C. biflorus* var. *nubigenus*, and another, possibly *Sieberi*, of the same section; *Scilla bifolia*, *Galanthus plicatus*, or some species resembling it, *Anemone appennina*, or *blanda*, in three varieties of colour—deep blue, pale blue, and pure white; *Colchicum bulbocodioides*, with eight or ten deep rose flowers, appearing together with the leaves; another species of *Colchicum*, and *Fumaria rutifolia*, all of which were found in great abundance and beauty, growing in the little openings of the forest. Many fine herbaceous plants, such as *Pæonies*, *Statice*, *Delphiniums*, *Astragalus*, &c., are, no doubt, to be found on these mountains in summer, but when I was there only the earliest spring flowers had appeared. The soil was a red loam, more or less mixed with vegetable soil and stones, and grows *Barley* well at an elevation of 4,000 feet. The natives of the country, at this time, were just beginning to come up to their summer quarters or yailahs, which, during the hot months, are much healthier and pleasanter than the plains. On my return to Macri I did not notice any new species of especial interest, except some Orchids which may be *Ophrys mammosa* and *iricolor*; but, owing to the changes which a fortnight had made in the vegetation of the trees, I was able to recognise several species which I had not seen in leaf before. The most characteristic trees of the low country are the *Valonia Oaks* (*Quercus Ballota*), *Ægilops*, and *Tinctoria*, and the *Pinus maritima* and *halipensis*. The *Oriental Plane* grows almost everywhere by water-courses and streams; and the *Wild Olive*, *Arbutus*, *Carob Tree*, and many shrubs, such as *Cistus*, *Judas Tree*, *Eleagnus*, *Daphne*, *Lentisk*, and *Christ's Thorn* (*Paliurus aculeatus*), cover the low hills to an elevation of 1,500 or 2,000 feet. On the higher mountains the trees are principally *Walnuts*, *Poplars*, *Apples*, *Willows*, *Apricots*, *Pines*, and *Oaks*; whilst the highest zone of forest is composed of *Junipers* and *Cedars*. H. J. ELWES.

(To be continued.)

* This may very likely be *Cyclamen cilicium*.

THE FLOWER GARDEN.

SOLANUM CRINITUM.

It is not generally known that this is one of the most precious of all the plants known as sub-tropical, when grown in warm sheltered spots in the southern counties. Mr. Fleming, of Cliveden, was one of the first to introduce this system to our gardens, and among his finest plants were large specimens of this *Solanum*, which, in the sheltered glades of Cliveden, attained huge proportions. With us, in favourable conditions, it reaches to 4 feet or more high, the leaves being not unfrequently more than a yard in length. According to the *Revue Horticole*, this plant was introduced to Paris gardens in the year 1862, and is a native of Guiana. It is, in addition to its fine size and dignified port, a plant of remarkable beauty owing to the texture of its leaves, which are covered with a deep rich velvet of tender green colour, with violet veinings set with

will suffice, or were those who have not acquired such extended use of the visual organs to see the plants arranged side by side, in neither case would there be the slightest difficulty in endorsing the appropriateness of the term miscellaneous as applicable in all its comprehensive fullness to the plants I am about to pass in review.

S. Cymbalaria of Linnaeus, though sometimes considered distinct from Jacquin's *S. orientalis*, is, I believe, no more than a synonym, at least in cultivation no tangible distinction presents itself. Haworth gave it, and one or two very closely allied species, generic distinction under the title of *Lobaria*. It is, however, a Saxifrage in all essential characters; an annual, or perhaps at times biennial, plant, whose whole structure is the very embodiment of tenderness and brittleness; its leaves are reniform, slightly cordate, and divided into from seven to nine lobes, and somewhat fleshy. In Nature its fragile stems are usually supported by the adjacent vegetation. The flowers are axillary, of a nice lively yellow colour, and produced in such abundance as, though individually small, to make the plant both striking and effective when in bloom. It appears to

Solanum crinitum.

spines. So very remarkable a plant deserves to be cultivated as an indoor plant where the climate will not permit of its being grown out of doors. Certainly there are many grown in stoves for their fine foliage, which are by no means so striking. It is multiplied by suckers from the root.

SAXIFRAGES.

By J. C. NIVEN, Botanic Gardens, Hall.

A Miscellaneous Group.

HAVING analysed the several divisions originally contemplated when commencing this series of articles, there still remains about a dozen or more species of Saxifrages that may, I think, be more happily allocated into a miscellaneous group than considered separately as representatives of a number of small sectional divisions. To those who are familiar with the appearance of the several species that I purpose introducing under this heading, a mental glance at the imaginary group

thrive best in a damp locality slightly sheltered from the direct sun; and, when once it is fairly established in a rockery, it is not readily lost, as it seeds freely, and never thrives better than when self-sown. The plant is of Eastern origin, growing abundantly in Asia Minor, Persia, and even the Western Himalayas.

S. Huetiana of Boissier is so closely allied that possibly it should be considered as only a variety; the chief characters, by which it is distinguished, are the smaller foliage, much less lobate, and the presence of a number of glandular hairs on the younger stems; it is also more purely annual in its duration than the former. The Caucasus and Tauria are recorded as its native habitats.

S. aizoides of Linnaeus, known as the yellow Mountain Saxifrage, is a plant of considerable beauty; its habit of growth is procumbent, its leafy stems trailing along the ground, and assuming an erect character as it comes into blossom; its leaves are narrow, linear-lanceolate in shape, and slightly ciliated, densely arranged along the trailing stems. The flowers, a brightish yellow, besprinkled in the interior with rich orange dots, are produced in small corymbose cymes during the months of July and August, or even later in

high bleak places, our plant being a native of Britain, and met with frequently along the margins of many of our northern mountain streams, where, under the influence of a continual exudation of water from below, in the form of cool springs, it is capable of bearing the direct rays of an unclouded mountain sun; nay, more, of growing with a luxuriance in all its parts, such as those who know it only as ordinarily grown in pots and artificial rockery would scarcely recognise or deem possible. I have myself seen it fully 12 inches in height, with a development of leaves and flowers proportionately large. Besides being a native of Britain, it is to be found nearly over the whole of Europe, Asia, and the northern part of the American continent, through which wide area it presents scarcely any appreciable variation, except in respect of size.

S. aizoides var. *atrorubens* of Bertolini, is more generally known as *S. autumnalis* of Vitmann; it is a more compact grower, somewhat later in blooming, and its leaves are a darker green than the original type; the flowers, also, as Bertolini's name indicates, are of a darker colour, owing to the petals being more densely suffused with the orange dots. The literal translation, however, of the name, as applied to the colour of this variation, is far from correct. Nevertheless, it is a desirable and very constant form, and well worthy a place in all collections of Saxifrages.

S. Hirculus of Linnaeus, the yellow Marsh Saxifrage, is synonymous with *S. lutea* of Gilbert and propinqua of Robert Brown. It is a dwarf caespitose or tufted grower, sending up its flowering stems to a height of about 3 to 5 inches, clothed with narrow linear-lanceolate leaves, ciliated towards the base, and terminated by a large bright yellow flower, or, in some instances, several flowers. The upper portion of the leafy peduncle is generally covered with short glutinous hairs, as are also the divisions of the calyx. Its time of blooming is towards the autumn, when its brilliant yellow flowers have a very attractive appearance, though not produced in such masses as in the previous species. To its successful cultivation, there are two essentials, viz., that it should be grown in peat soil, and have a continuous supply of root moisture, as well as full exposure to the sun. Though somewhat rare in Britain, it has an equally wide geographical range, through all the high mountain bogs in Europe, Asia, and North America, occurring even in a slightly modified form in Sikkim, as recorded by Drs. Hooker and Thompson.

S. Hirculus var. *major* is a distinct form with broader foliage, and flowers fully twice the size of the normal species; in fact, the term *major* is most appropriate to the development of the whole plant. I suspect this variety, although not recorded in the "Flora," is also British, as I have some dried specimens whose habitat is marked as having been found in Berwickshire.

S. flagellaris of Willdenow, though differing in foliage and habit from *Hirculus*, is closely identified with it as regards bloom, having flowers about the same size as the *major* variety of that species, and of an equally intense brilliant yellow. These are produced on the summit of a simple or unbranched stem, which rises to a height of about 4 inches, clothed with linear-lanceolate leaves from a dense rosulate arrangement of radical foliage, the whole of the leaves being beautifully ciliated with glandular hairs. From the axils of the lowermost leaves are developed on all sides a series of thread-like stolons about 3 inches in length, each terminated with a small bud, which ultimately develops into a separate and independent plantlet; hence, originating the popular name applied to it by the sailors in the Arctic regions of the Spider Plant, the parent representing the body of the insect, the radiating stolons the legs, and the terminal buds the feet, by no means an inapt comparison. This plant is, in my estimation, the very gem of the whole genus; it was introduced in the year 1851, in a living state to Britain—nay, more—in a flowering state; having been sent home by Dr. Sutherland, from Melville Island, he being connected with the Admiralty boats there in search of the unfortunate "Erebus" and "Terror." It was my good fortune to open the case, and never was there such an instance of "love at first sight" as this; and, singular enough, without knowing the name given by the sailors, I exclaimed, here is a veritable "Spider Saxifrage," so it has been twice christened. Its life was short, as it never recovered the dry atmosphere of the artist's studio. It is a native of the extreme Arctic regions, and also of the Caucasian and Altaic Alps, as well as the Himalayas, where, at great altitudes, it appears under various forms, to which as many distinct specific names are given, such as *macrocalata*, *spinulosa*, and *setigera*. I am in hopes of receiving a consignment of it from Nova Zembla some of these days.

S. stellaris of Linnaeus, or the Star-flowering Saxifrage; though it cannot be classed as a showy species, nor is it as readily amenable to cultivation as some of its congeners, it is by no means to be despised; its radical leaves are few in number and hairy; in shape they are broadly obovate and emarginate, narrowing down the sides of the short petiole, slightly and irregularly indented in the margin; the inflo-

rescence consists of a few-flowered panicle, 3 to 6 inches in height; the flowers are white, suffused with a pinkish tinge, and with two yellow spots near the base of each petal. It is essentially a bog plant, and generally met with growing near the margins of mountain rivulets, or scattered in an isolated manner over the surface of our mountain bogs, where, as a rule, the floral element is deficient; hence, its simple flowers are the more appreciated. It has a wide geographical range through Europe, Asia, and America, especially in the northern regions of the last two Continents, and appears to vary in form a good deal; two of these forms are met with in Great Britain, the entire-leaved one being confined to the very highest mountains in Scotland.

S. Clusii of Gouan includes that known as *Leucanthemifolia* of Lapeyrouse, but not the North American plant of Michaux known by that name, which is perfectly distinct. This species is very closely related to the preceding, but has larger leaves, the margin for the upper half more regularly dentate and supported on longer foot-stalks; the inflorescence is foliaceous, the flowers are more numerous, and the foot-stalk shorter than those of the Star-shaped Saxifrage. It is a native of the Pyrenees and some parts of the Tyrol, and affects similar upland bogs, as does our own more familiar species. My own impression is that both this and the foregoing species are little better than biennials; and, further, in cultivation my experience is that they are not very readily raised from seed; vegetating pretty freely, but dying off before the true rough leaves become developed.

S. nivalis of Linnaeus, familiarly known in our Alpine districts as the Mountain-clustered Saxifrage, is a dwarf-growing plant, with a tufted cluster of oblong-ovate leaves, downy in a young state, but glabrous when fully developed, slightly coriaceous, and acutely crenate at the margins, from the centre of which rises a dense compact inflorescence of small white flowers, rendered more attractive by the beautiful chocolate colour of the anthers. It is a native of the mountain districts in Wales, Scotland, and Ireland, but by no means plentiful. In cultivation it ought to have an abundance of root moisture, and with that may be freely exposed to the sun; but, failing that essential, it ought to be planted at the north side of a good block of stone. It is by no means a local plant, being met with through the entire northern region from Vancouver's Island to Kamtschatka; under slightly differing forms, *S. nigricans* of Fischer, as applicable to the dark anthers, and *S. primulefolia* of Willdenow are both synonyms of this species.

S. virginianensis of Michaux, or *S. virginica* of Nuttall, are synonymous terms applied to a plant very closely related to the preceding species; it is, however, of considerably greater stature, the leaves broader and more crimped or undulate at the margins, and suffused with a downy pubescence, both above and below; the inflorescence is more branched and devoid of any bracteate appendages. Beyond these distinctive characters the Virginian plant might be taken as nothing more than a *major* form of our Clustered Saxifrage, and to it the same cultural remarks will be equally applicable. It is a native of the Rocky Mountains, from Virginia northwards.

S. pennsylvanica of Linnaeus we take as the type upon which H. Worth established his genus *Micranthes*, given to this section on account of the exceedingly diminutive character of the flowers. Springing from a short fleshy underground stem, the leaves rise to a length of from 6 to 9 inches—oblong in shape, and spatulate at the base, clasping round the stem; the margin is sparsely toothed, and the whole surface above and below is covered with a dense pubescence; from the centre of the mass of leaves rises a naked flower-stem to a height of about 18 inches, branching at the summit, and covered with a dense arrangement of small flowers with narrow greenish-coloured petals, which, were it not for the orange anthers, would be almost wholly devoid of beauty, but the latter, when seen in a mass of bloom, have really a charming effect, requiring, of course, a moderately close inspection. Neither this, nor indeed any of the three species belonging to this group will ever become popular plants, but they are valuable where a collection is grown as adding one more indication of the wide diversity of appearance which a single genus is capable of assuming. As the specific title infers, this plant is a native of Pennsylvania and also of Virginia, Ohio, and Kentucky, occurring as well in Canada.

S. pennsylvanica var. *glabra*, is sometimes called by the specific title of *marylandica*, for which, however, there is no authority beyond that indefinite one known by the title of "Hornerum;" it is, unquestionably, no more than a glabrous form, and is referable to Sweet's variety, "*semipubescent*," as endorsed by Engler. It grows abundantly in Maryland.

S. erosa of Pursh, obtains its name from the singularly irregular dentate character of the leaves, giving them the appearance as though they had been eaten away at the margin by some predatory insect; besides this, the leaves are shorter and broader than in the preceding species; the flower-stem is not so tall and much more

fleshy; the petals broader and more expanded, and, I may add, a thoroughly inconspicuous, though, perhaps, none the less constant character, that the seeds of this species are covered with minute tubercular processes. It is a native of Virginia, North Carolina, and along the entire range of the Alleghenies. It is one of those I have not at present in cultivation; should any Saxifragacean friend possess a duplicate plant, it would be a very acceptable addition to our collection.

S. hieracifolia of Waldstein and Kitaibel, is the third and last species of the *Micranthes* section which comes under our consideration. It is synonymous with *S. plantaginifolia* of Hooker—a much more appropriate name by the way—but, seeing that the former was first in the field and has established a tolerably wide reputation, we will not disturb it; it is similar in appearance to both the preceding species, its leaves being larger, more densely hairy, entire, and slightly revolute at the margins; the inflorescence more branched and distinctly bracteate; indeed, in one variety, the bracts become actually foliaceous. The petals are ovate, not linear, and the seeds are smooth. This is the only species in this very distinct section that possesses a European as well as a Transatlantic habitat; in fact, until Richardson's expedition into the far northern regions of the Hudson Bay Territory, it was supposed to be altogether European and Asiatic. It occurs in the Carpathian Mountains, in Norway, Spitzbergen, and in the Altai chain, also in Siberia. When planted in rich damp soil it acquires an enormous development, both in foliage and height of flower-stem, but it is liable to rot off in the winter when thus stimulated.

S. peltata of Torrey stands as the sole representative of Engler's section, *Peltiphyllum*, and is, we believe, the only peltate Saxifrage we have. Its large leaves (by no means fleshy) rise from a somewhat thick rhizome, and are supported on longish petioles; the margin of the leaves is twice dentate. I have not yet had the pleasure of seeing it bloom, nor, indeed, have I seen the figure of it, so must content myself by saying that it is both an interesting and distinct addition to the genus, and one which, though of but recent introduction, will become a popular plant by and bye. It is a native of California, the original dried specimens from which Torrey described the species, having been sent home by Hartweg, when out as collector for the Royal Horticultural Society; the living plants are, however, of much more recent introduction.

S. aconitifolia of Fielding and Gardner has been, I think, very properly removed from the genus Saxifrage by Nuttall, and described by him under the distinct generic title of *Boykinia*; it is, perhaps, the only species, as endorsed by Engler, that I should like to see removed from the Saxifragaceae. The general habit of the plant, accompanied by the valvate aestivation of the calyx, which we do not meet with in any other species, appears to me to give it a good claim to generic distinction. For this reason I have selected it as the *type* of my descriptive list. It is a strong-growing plant, sending up leafy stems, terminated with paniced cymes of small white flowers, to a height of 18 inches or more; its leaves are cordate and palmately divided into seven lobes, having somewhat the appearance of the more entire forms of the *Aconitum* or Monk's-hood, from whence its specific title is derived; the flower-stems are covered with brown glandular hairs, and the ovary undergoes considerable development during the ripening process, by which a globose fruit, at least three times the size of the original adherent calyx is formed. This plant is very impatient of pot-culture, but grows well, and seeds freely planted out in one of our bog beds, where we have had it for years, and where a supply of self-sown plants is generally available. It is a native of North Carolina.

When I commenced the series of articles on Saxifrages, which I now bring to a close, I by no means contemplated anything like the lengthy and detailed analysis that I have endeavoured to give; possibly some of my readers will have had their stock of patience fully exhausted long before reaching this point; if such there be, I would add for their consolation that there are yet some sixty or seventy described species which I have not even named. Few, if any of these however, are in cultivation; at least it has not been my good fortune to come across them, except in herbaria, or as figured in rare botanical works. This, however, I can say that some of them are even more beautiful than any yet introduced. What gems are to be found on the lofty passes of the great Himalayan Chain, and also on the Cordilleras in South America, to all of which, culturally speaking, we are perfect strangers. Doubtless, besides these, there are many species not yet described that will at some future period reward the investigations of our Alpine tourists. Such men as our friend Mr. Maw, whose eye possesses that rare gift of being able to note at a glance, the distinctive characters of plants, rarely returns from one of his Continental trips without something new; yea, even amongst Saxifrages. If apology be necessary for introducing into my list species that are perhaps purely botanical, I can only say that in an extensive

correspondence that has resulted from my series of articles, I find that there is a thirst for information rather more on the botanical and rare than on the common and popular sorts; for this reason I have enlarged somewhat on what was my original intention. The correspondence I have just alluded to, while entailing considerable additional labour on my part, has been the means of giving me a large amount of information. At some future time, I may analyse the same and give your readers that are interested in Saxifrage lore a sort of postscript article, containing such items of information, thus acquired, as I may deem of general interest. I must not, however, conclude without bearing my testimony to the valuable assistance I have derived from Dr. Engler's exhaustive "Monograph," to which I have had frequent occasion to allude. I question much if any genus has ever been more thoroughly and perfectly analysed—exhaustive is the only correct word to apply thereto—extending, as the analysis does, over some 300 pages of closely printed matter. Its only defect—if defect it can be called—is in the fact that the popular descriptive part is in German, not in English, necessitating its translation before its valuable information can become available to non-Teutonic minds.

PLANTS FOR ALL WEATHERS.

If you have herbaceous plants on the brain, and live on a chalk rock with only 3 feet of soil, and have, into the bargain, continuous easterly winds in spring, and sharp nightly frosts, followed by a summer of intense heat, and no rain worth mentioning for five months, you will keep a keen look-out for those plants which bravely face cold, heat, and drought, and look fresh and bright under the most adverse circumstances. I am in the predicament just mentioned; and, for the last month or two, my desponding horticultural heart has been from time to time cheered by the irrepressible vivacity of a few plants whose names, I think, deserve to be made public. *Pyrethrum niveum*, for which I am indebted to the kindness of Mr. Maw, who brought it, I believe, from Morocco, has been for weeks a tall bush of bloom white as driven snow. I could see it standing out conspicuously among its floral brethren half a mile off. It comes very close to our British *P. Parthenium*; but is easily distinguished by its taller growth, larger flowers, and dense inflorescence. *Convolvulus althaeoides* is now, from 9 a.m. to 2 or 3 p.m., one of the prettiest things in the garden. I have got it thoroughly established in a bed of Roses on their own roots, over which I let it run and twine at will, and very lovely are its thickly-scattered delicate pink blooms. Its congeners, *C. linearifolius* and *mauritanicus*, are also very good plants for standing drought. *Michauxia campanuloides* has, contrary to my expectation, been wonderfully fine this season. Two or three plants, planted in a clump, make a grand show when all their great white Passion-flower-like blooms are expanded. *Salvia pratensis* and its varieties, bicolor and rosea, *S. limbata*, *sylvestris*, and *bracteata*, have all been wonderfully fresh and bright. A tall bushy species, with clear white flowers, which I had under the name of *S. candidissima*, has also been very ornamental; and the profuse pinkish-lilac blooms of *S. lanceolata* have often raised my drought-dashed spirits. *Æthionema saxatile* is a gem of gems for a dry season. No amount of dust, heat, or dryness seems to check the luxuriance of its growth, or pale the brightness of the rose-coloured sheet of blossoms with which it covers the rock-work. I have not tried *Æ. grandiflora*; but, if it is true to its name, and as good as its congener, it must be grand. *Aphyllanthes monspeliensis* is a plant with which I could never succeed till the present year, but a large plant on a bit of dry rock-work was for a fortnight a perfect mass of blue stars. It was well set off by its beautiful little neighbour, *Arenaria purpurascens*, whose delicate purple and white blossoms quite hide the leaves. Amongst the *Geraniums*, *G. arvense*, with its great magenta blooms, and *G. sylvaticum album* were singularly beautiful and fine, the latter almost rivalled *Pyrethrum niveum*. *Erodium petraeum* and *maeradenum* have also been finer than usual. Amongst the Saxifrages, *S. Mawiana*, *Willkommiana*, *purpurascens*, *Tazetta*, and *pyramidalis* stood their ground well. *Phlox divaricata*, which hitherto I have utterly failed to grow, was for weeks a picture of health and beauty. Amongst the *Campanulas*, *C. persicifolia*, *coronata*, and *maerorbiza* have stood well. *C. isophylla alba* and *soldanelliflora* fl. pl., which are just coming into bloom, also

look very fresh. The great yellow blossoms of *Scolymus grandiflorus* and *Coreopsis lanceolata* are now looking wonderfully gay. *Melittis grandiflora* and *Lunium Orvala* have been finer than ever I knew them. *Betonica grandiflora* has done well, and *Pentstemon speciosus*, *Dianthus neglectus*, and *Aster alpinus albus*, three plants with which hitherto I have been able to do nothing, have been as good almost as I could wish them to be. *Dianthus arenarius*, *Atkinsoni*, *caryophylloides*, *fimbriatus*, and *giganteus* have all been good. Much to my astonishment, a self-sown patch of *Mimulus cupreus*, which stood the winter, was a week or two most brilliantly gay. *Iberis Prunellae* and *ciliata*, *Gaillardia bicolor*, *Lilium Martagon*, and its vars. *album* and *Catanii*, *Onosma echinoides*, *Achillea Ptarmica* fl. pl., *Teucrium pyrenaicum*, *Nepeta grandiflora*, *Peltaria alliacea*, *Phlomis frutescens*, *Pentstemon glandulosus* and *Jaffrayanus*, *Gypsophila prostrata*, *Scabiosa parnassiae*, and *Helium autumnale* have borne out the heat and drought wonderfully well. *Dahlia Cervantesi* and *Exogonium purga* promise well, and last, but not least, *Asteriscus maritimus* is the pink of freshness and beauty. H. HARPER CREWE.

Drayton Beauchamp Rectory, July 21.

CLEMATISES FOR PILLARS.

THERE is scarcely a more effective way of growing some of the new hardy Clematises than as pillar plants. It is not always one can find space to plant them against walls, or they may be already covered with evergreen climbers; and the same may hold good as regards trellises. Where creepers are planted as screens or coverings they should be, for the most part, at least evergreen, for it must be remembered they are required for permanent decoration. It is, however, in the form of pillars placed here and there in shrubbery borders that I commend these Clematises. There is, in general, too much uniformity about such borders—dwarf plants in front, taller ones behind, and, as a background, *Fuchsias*, or it may be *Dahlias* and *Hollyhocks*. Now anything that varies this monotonous line ought to be welcomed; and these Clematises can be made to do this well. My plants, now perfect pillars of flower, are trained to some Hop poles, 8 feet in height. The plants were put into the ground three years ago, and are now well established. For two seasons I adopted the practice of cutting away to within 9 inches or a foot of the ground all the previous year's growth, but last season I varied the practice by not removing any of it; but, as usual, in November I forked in some good decayed manure about the roots, and in March last mulched well with cow-dung. The growth made last spring was tied in slightly to the poles as made, and it covered them from base to top; and, instead of having flowers only at the top of the poles, the plants present the appearance of perfect pillars. I shall now cease altogether to cut back hard to the ground, as is usually directed, and shall content myself with merely thinning out the oldest wood, leaving the growth of this summer to yield the flowering wood for next season. I have *Jackmanni*, *Rubella*, *Prince of Wales*, *Star of India*, *Magnifica*, *Lanuginosa*, *Lady Bovill*, *Lanuginosa nivea* (the finest pure white Clematis in cultivation), and *Rubro-violacea*, in grand condition. A few ties made round the poles, and a chief one to a nail driven in at the top, keep the plants from being driven about by wind. I obtained my Hop poles from Kent, at the cost of about eightpence each. Having been dipped in creosote, they will withstand several years' use, if drawn out of the ground in the autumn and stored away during the winter. When I remove the poles, I thin out the old wood and coil what remains round; it is then secured to a few short stakes, and in the case of *Lady Bovill*, *Lanuginosa*, and any of a tender character, some straw or Fern is securely placed about them to carry them safely through the winter. As soon as the buds begin to swell in spring, the poles are replaced, and the Clematises tied securely to them. Now that the plants are in full bloom, an abundance of water is absolutely necessary. The Clematis is a strong feeder; it throws out a great number of fleshy roots, which require ample nourishment. In addition to the mulching of manure, I apply some guano mixed with water, or some liquid manure from a stable diluted with water. The result is apparent in the size and brilliant colouring of the flowers.—*Field*.

Propagation of Hard-wooded Aralias from Cuttings.—The *Araliaceae* in general, with the exception of those hardy species which are easily propagated from portions of the stem, are difficult to increase from cuttings. Those taken from the end of the main stem or branches, notably the Mexican genus *Oreopanax*, are often a very long time before they take root. Hence, there is an unfortunate delay in the spread of these splendid plants. There is, however, an

excellent method certain to lead to success, and this is to select only the lateral or, as it were, adventitious shoots which are formed on the main stem. These should be taken off young and at once placed in heat, just as we should treat ordinary soft-wooded subjects. This simple system has been successfully employed by M. Cornelis, head gardener to Viscount Vigier, at Nice, in the propagation of *Oreopanax dactylifolia* and other difficult species.—*Illustration Horticole*.

VIOLETS FOR NEXT WINTER AND SPRING.

If you would wish to have the best Violets which the garden can grow—and why not?—then begin at once, as follows:—Heavily manure and deeply dig a sheltered piece of ground—a south or west border, unless the garden is specially hot or dry—either near a wall or in the open quarters, according to circumstances. Break the surface fine in the digging, or rake it smooth; and, if the earth is of a loose texture and dry, as most soils have been this year, then run a roller over it, and tread it almost as firm as you would an Onion bed. Then proceed to mark it out in rows, a foot, 18 inches, or 2 feet apart, according as your ground is plentiful or scarce. Then go to your Violet plants, trowel and basket in hand, take off each rooted runner or shoot, or each distinctly-showing roots, and proceed to plant them at distances of 6 or 9 inches, or even 1 foot apart, if you can afford that space. Insert the roots carefully, and bury roots, runners, and all right up to the tuft of leaves, and even, in the case of plants without roots, place the short stems into the earth, and press the soil firmly in all cases round the collars. Unless the weather is showery, water them into their new homes; and, should dry weather again set in, they must not be allowed to flag. In ordinary weather they are seldom much trouble, but strike root freely, and at once, in the new soil. After they have become established, keep the ground free from weeds by frequent hoeing; and, should the plants produce runners and flowers—and they sometimes do both—pick them off. During the autumn they will form dense heads, and may yield a hundred or more Violets. About the beginning of October they will begin to flower, and part of them may be potted for house work, part removed to the foot of south and west walls or frames to yield a constant supply of Violets through the winter and early spring. Those who once adopt this system must not try to flower the same plants two years running. The difference in the produce of young plants and two-year-olds is marvellous, and the older the Violet the poorer the bloom. When the young plants have become established, destroy all the old ones; or, what is better, plant them out in the woods and pleasure grounds. Another plan answers almost equally well. As soon as the Violets have finished flowering take them up and divide them, retaining as much root to each as possible, and plant as already directed, rejecting any of the stems and roots that are unhealthy or diseased. Little is gained, however, by this method, unless it be that plants so treated need less water in dry weather when first planted out than under the other plan. Others, again, advise raising plants of the single varieties from seeds, an operation in which I never could find any advantage; but, on the contrary, a great loss of time. As to varieties. The single Russian, *Czar*, and *Victoria Regina* are the best single blue varieties. The single white is also useful, and a single pink or red is liked by some for variety. The double blue Russian or tree Violet and the Neapolitan are assuredly the best of all the doubles. The double white is also useful for variety, and some say it is sweeter than any other. When all are so sweet it is difficult to determine; but, if there is a difference, the *Victoria Regina* has it assuredly.—*Country*.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Chelone barbata antwerpensis.—This fine old herbaceous plant is now seldom or never seen, but it is one that would give satisfaction everywhere. It is a summer-flowering plant of long duration, and has fine handsome spikes of scarlet flowers, which are produced in abundance in a good heavy soil. The plant requires dividing and replanting every other year in fresh soil, like most other hardy plants.—*Flora*.

The Double-blossomed Scarlet Lechnis.—I send for your inspection a few blooms of this *Lechnis*, which is now in full blossom in my garden. I have fifty fine plants of it, which are all extremely brilliant in colour. I am told that this *Lechnis* is rather a rare flower; is it so, or not?—M. MILLER, Upway, Dorchester. [The flower-heads of this *Lechnis*, sent by our correspondent, were as large and showy as those of the best of our double-flowered scarlet Geraniums. It is a very old and handsome border plant, but one not half so extensively grown as it ought to be.—Ed.]

Primula officinalis.—I met with this name lately in the catalogue of a German nurseryman, and have searched through a great many books to find out what it is, but all in vain. Can you tell me? I should, perhaps, have contented myself with the supposition that it must be the common *Primrose*, but for the only allusion to it which I can yet find; this is in "Hardy Flowers," where it is mentioned that "the common Oxlip is a hybrid from *Primula vulgaris* and *P. officinalis*," but the latter plant is not described.—W. T. P. [*Primula officinalis* is one of the names of the common *Primrose*—Jacquin's name.—Ed.]

A DWARF JAPANESE TREE.

WHEN in America, in 1870, we were much interested at the sight of various Japanese curiosities in the way of trees and plants brought from that wonderful country by Mr. Thomas Hogg, to whom we are indebted for the introduction of a good many valuable Japanese plants. It is most curious to observe that while the trees are dwarfed and aged beyond what one would conceive possible, they are in perfect health and character. Recently the Comte de Castillon has sent a sketch (from a photograph) to the *Revue Horticole*, which shows, almost as well as the living object could, the aspect of one of these trees, so much loved by the Japanese gardeners. It is a specimen of *Pinus densiflora* var. *albifolia*, supposed to be more than a hundred years of age, the stem almost filling the vase in which it has grown so long. Whatever may be thought of the wisdom of growing such productions (to us it seems very much less objectionable than clipping trees into strangely artificial shapes), every person with the least knowledge of pot-plant culture will admit that to keep these dwarfs in perfect health for so many years is a remarkably skilful performance.

THE PLANTING OF WEST HAM PARK.

SINCE West Ham Park, near Stratford-le-Bow, has become public property, and its eighty acres of well-wooded land devoted to the healthful and rational enjoyment of the people of that district, the following account of its first occupation may not be uninteresting to the readers of *THE GARDEN*:—Ham House was built and the park laid out by Dr. Fothergill, a member of the Society of Friends, and the most eminent physician in London from the year 1750 to his death in 1780. He was a scholarly man, of refined tastes, great benevolence, and an excellent botanist. He had travelled much in America, and observed with admiration the glory of her forests, especially the flowering trees that fill the woods with such extraordinary beauty. In the early part of the last century the forests were more dense and frequent than at the present time of increased population. One of Dr. Fothergill's voyages to and from America was made in the same ship and with the same captain, a man of much nobility of character and kindness of disposition. During the voyage home the doctor was taken ill, but recovered under the watchful and almost brotherly care of the good captain. While the ship lay in London, waiting for loading, the captain was attacked by fever. Dr. Fothergill was constant in his visits, and had the satisfaction to see his patient's health re-established. Convalescent, and ready to take charge of his ship again, the captain requested the doctor to name his fee. He replied: "Under divine favour thou saved my life on the sea, I thine on land; our obligations, therefore, are mutual." "Then tell me," said the captain, "is there no way by which I can serve you?" The answer was characteristic—a request for a hog'shead filled with mould from a certain locality which he named, and well known to them both. He had observed in his travels the profuse blooming and shedding of fruit and seeds in more open parts of the forests and by the river-sides, and had conceived the idea that a portion of the earth into which these seeds had fallen might be brought to England, and that, with careful management, a number of young plants might be secured. His friend entered heartily

into his project; and, in process of time, three hog's-heads reached Ham House containing the desired treasure. A space of ground was cleared and prepared for its reception, and the doctor had the pleasure of seeing a plentiful growth, consisting of *Catalpa syringifolia*, *Magnolias*, *Robinias*, *Tulip* and *Judas* trees, with *Oaks* and *Maples*. This abundance he imparted to his neighbours, for most of the older gardens about Plaistow and Upton possessed duplicates. During a short residence in the neighbourhood of West Ham, in the year 1856-7, I had an opportunity of seeing the spot where the trees had been raised, and heard the story I have now related. The space of ground occupied a few roods, and was dotted over by *Rhododendrons*, *Azaleas*, and *Kalmias*. West Ham House and Park were built and planned by a good and great man, and is now given to the people. May they use it as a gift of no ordinary value.

A. D. H.

New Plants found at the Antipodes.—During a recent trip to the Hume River, in New South Wales, Baron Mueller met with several plants that were either new or extremely rare. In a gully, probably 4,000 feet below the level of the surrounding country, he discovered a species of *Bertya* (specifically named in honour of Mr. J. Findlay). The genus has long been known to Australian botanists, but *B. Findlayi* differs from all the rest in point of size, being sometimes 25 feet high. He also discovered on Mount Kosciusko, 7,000 feet above the sea level, a small species of *Pladtago* (*P. Gunnii*). This minute plant seems to be peculiar to high mountains, and differs from those species hitherto known in New South Wales. Besides making several discoveries of this kind, the Baron ascertained from personal observation that the so-called "Tasmanian blue gum" is really indigenous in the southern part of this colony; and that, in the same locality, several species of aquatic plants, but little known to the scientific world, occur plentifully. To these interesting facts he adds the discovery of a new Orchid (*Bolbophyllum Taylori*) by Mr. Norman Taylor; and several new plants from Lord Howe Island (particularly an *Aster*, which rises to the height of a small tree), and also a Fern (*Lomaria Fullageri*), from the same island, with a long caudex, and numerous pinnatisect fronds. Mr. Norman Taylor has recently sent specimens of Ferns from the Endeavour River. They are not new to botanists, but the collection of

A Japanese dwarfed Pine.

them is very interesting, as illustrating the geographical distribution of these graceful plants. Amongst the most remarkable of those not found in the neighbourhood of Port Jackson, are three species of the climbing *Lygodium*, and the curious and variable Fern, *Ceratopteris thalictroides*, which grows in pools of salt water not far from the sea, and in marshy places. Sir William Hooker, in his "Species Filicum," has a long account of this strange plant, and he shows that the different forms of it, as existing in Asia, Africa, and America, really belong to one and the same species. In addition to these, Mr. Taylor collected two species of *Gleichenia*, one of *Davallia*, one of *Adiantum*, three of *Polypodium*, one of *Doodia*, two of *Asplenium*, two of *Aspidium*, and one of *Acrostichum*. Several of these will prove interesting to cultivators of Ferns.

The Indestructible Paint Company.—Paint, says the *Builder*, which will readily preserve stone, brick, and cement is a desideratum, and the Indestructible Paint Company, Cannon Street, claim that their material will do so: farther, they produce a paint which resists acids, alkalies, and heat. The fact that their stone-solution is the one selected for St. Paul's Cathedral is sufficient to give it a claim on our attention.

THE INDOOR GARDEN.

STOVE CLIMBERS.

ALLAMANDA CATHARTICA.—Where a good specimen of this is trained along a rafter in a sunny aspect, nothing can give greater satisfaction. When in flower, its beauty is undeniable; and, even when out of blossom, its fresh green foliage is by no means unattractive. Pot-culture suits it best; as, when planted in a border, the roots are inclined to ramble—a circumstance which causes the shoots to become gross, and the plant to make wood instead of producing flowers. All Allamandas require a season of rest, when they should be kept dry; and, when in pots, that can be more easily effected than when planted out. In summer, Allamandas may be readily struck from cuttings, each being put in a 2-inch pot, and they should then be plunged in a bed of tan, leaves, or sand, and covered with bell-glasses, in a temperature of 70°. When rooted, each may be transplanted to a 5-inch pot, in which it should remain until spring, when they may be shifted into 7-inch, and subsequently into 10-inch pots, in which they will bloom. I have seen them succeed well in soils of different kinds; but nothing suits them better than a good fibry loam, mixed with a quantity of half-inch bones, sand, and charcoal. No manure-water should be given until they show flowering laterals, when liberal quantities may be advantageously allowed them.

DIPLODENDRA AMABILIS.—Dipladenias being plants unsurpassed in beauty, no plant stove can be properly furnished without them. *D. amabilis* may either be grown as a roof plant, or on a balloon-shaped trellis, which sets it off to good advantage. Like the Allamandas, it does best in a pot, for either trellis or rafter. Being rather shy to start into growth after resting, judicious management during the autumn and spring months is absolutely necessary, especially as regards watering, if considered worth keeping for flowering a second year; but, as autumn-struck cuttings form good flowering plants by the following autumn, old plants may be dispensed with. As regards compost, equal proportions of loam and peat, with a free admixture of dry cow-dung, charcoal, and sand, answer admirably. It dislikes being cut or wounded in any way; even the leaves, if injured in the least, soon show signs of decay. *D. Bolivensis* and *D. splendens* are also equally beautiful, but *D. amabilis*, being a favourite with me, I prefer to all others.

JASMINUM SAMBAC.—This, although strictly speaking a stove plant, may be grown well in a warm greenhouse; but, as a rule, a stove suits it best, and it should be planted out in a warm rough loamy border. In greenhouses it does best in a pot, as borders in such houses are generally colder than those in stoves. The best plan is to train two leaders up the rafter, and to spur in the young shoots, as flowers are produced most plentifully on old spurs. The best plant I have ever seen of it was inarched on *Jasminum multiflorum*, the roots of which seemed better suited for comparatively cold soil than those of *J. Sambac*. It was planted in a cool greenhouse, and ran through a broken square of glass into a warm Fernery, where it flowered most abundantly, and made strong healthy wood. Two leaders are better than one, inasmuch as one can, at any time, be renewed by training up a young shoot from the bottom.

STEPHANOTIS FLORIBUNDA.—This fine old stove climber may either be grown to almost gigantic dimensions or confined to a comparatively limited space. It should, however, have plenty of room, as the more the shoots are allowed to develop themselves, the more and better are the bunches of bloom. The latter are all produced on the young wood; hence, a quantity of young shoots should be kept up from as near the base as possible. Attention must also be paid to the training of the young shoots when growing, as they increase very fast, and are apt to get twisted together in such a manner as to render it difficult to unravel them without breaking or splitting them. After the flowering is over a quantity of the old wood should be removed, selecting such branches as have got least young wood upon them. Brown scale is almost sure to attack this plant, but it is easily removed by sponging with soap and water, and then giving a good syringing with water at the

temperature of 120°. The best soil for the *Stephanotis* is equal quantities of leaf-mould, loam, and peat, to which may be added a good allowance of rough sand. When grown in pots, plenty of drainage should be given, and over it should be put a covering of half-inch bones, but planting-out in the border is preferable to pot-culture.

HOYA CARNOSA.—This old-fashioned but beautiful plant requires, when growing, a good deal of water; when at rest, little is needed; but it should never be allowed at any time to become altogether dry. It will be found to succeed best as a pot plant trained on a trellis, or it may be trained on a back wall of a stove, but is not a good plant for a roof. The soil best suited for it is a turfy sandy loam, mixed with brick bats, lime rubbish, and charcoal. It may be propagated by means of cuttings, layers, or leaves, the cuttings being best. The best plant I ever saw of it was trained on the back wall of a half-span-roofed stove, where it grew most luxuriantly, and flowered in perfection. The wall was kept rather damp by syringing it; numerous branch-roots got attached to it, which, although no improvement in point of appearance, seemed to greatly assist its growth.

CISSUS DISCOLOR.—This, on account of the beauty of its leaves, deserves a prominent place among stove climbers. Like most foliage plants it dislikes being syringed, but it requires a moist atmosphere to bring out the beauty of the leaves in perfection. Pot-culture suits it best, for when planted out, it can never be properly dried off, and after that happens, if it ever starts again, growth is comparatively late and slow. In a pot, on the contrary, when the leaves begin to lose colour, the plant can be removed, and a *Stephanotis* or other ever-green climber put in its place. The *Cissus* should then be carefully dried off and placed in some dry warm corner, until it shows signs of starting again into growth, when it may be shaken out and potted afresh, watering carefully until it is fairly set agoing. A compost consisting of fibry peat, brick-bats, broken freestone, and sand, is all that is required. To the foregoing may be added *Clerodendron Balfourii*, *Bignonia ornata*, *Bougainvillea speciosa*, *Echites rubra-venosa*, *Ficus repens*, *Ipomoea Horsfalliae*, *Kampteria Roscoeanae*, different kinds of Passion-flowers, Vanilla, and others.

JAMES MORRISON.

Aloe Bainesii.—This is now growing at Kew, and is a most remarkable plant. It has tufts of glaucous-green distantly-spiny leaves, a foot long, and 2 inches broad, crowded at the end of its branches, and was discovered by Mr. Baines, after whom it is named, in the northern part of Natal. From Mr. Baines's letter to Dr. Hooker, we learn that this arborescent Aloe was growing on the slope of a rugged hill, overlooking the sources of the Inada or Inanda Rivulet, a tributary of the Tugela River, and perhaps nineteen or twenty miles north-east of Greytown. Early in June, 1873, while proceeding to examine a hill near the Tugela, reported to be auriferous, Mr. Baines first met with these arborescent Aloes, and remarked their similarity to the great tree Aloe of Damaraland, but also noticed that they were different from that kind.—*Florist*.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Salvia gesneræflora.—This is one of the finest scarlet-flowered decorative plants for the conservatory during the winter and 1 spring months. It is allied to *S. fulgens*, but the latter is a summer-flowering species.—M.

The Double-flowering Pelargonium "Jewel."—This is one of the very best of the recently-sent out sorts. It is robust, free-flowering, and a very fine dwarf Tom Thumb kind. It opens kindly, and the individual flowers are of great substance.—K.

Nothoscordum fragrans.—This pretty bulbous plant has been flowering freely in the Heath-house at Kew. It is nearly allied to the Alliums, and bears clusters of white flowers on a slender scape about a foot high. The foliage is slender and glaucous, like that of *Milla uniflora*. It is a plant well worth growing on account of its flowers, which are most deliciously scented.—B.

Mesembryanthemums.—These are not only useful as window plants—a purpose for which many of them have been used for many years—but, as rock-work plants, in sunny positions in the conservatory or greenhouse, they have few equals. Many of the species luxuriate when planted outside in dry sandy soil during the summer months.—B.

Campanula Portenschlagiana.—This pretty bell-flower is now in flower in the greenhouse at Kew, and, in spite of its long name, it is well worth attention. It is prostrate or pendulous in habit, and bears large silver-shaped blue flowers an inch and a half across. Its leaves resemble those of *Veronica Halcama*, or a small-leaved form of the common Birch. As a plant for a bracket, or hanging-basket in the window, it well deserves a trial, being a most profuse bloomer.—B.

THE GARDEN IN THE HOUSE.

DINNER-TABLE DECORATION.

Forms of Stands.

NE of the principal things to be decided before entering farther into details, is the stands in which the flowers are to be arranged; of these there are so many varieties that it would be impossible to enumerate all; I shall, therefore, only select those which I have in use myself, and with which I have taken prizes. One of my favourites is the March form of stand, with a trumpet rising out of the top tazza. This I have always considered most effective; it is easily dressed, and not expensive to purchase; its greatest fault (and one which belongs to the true March stand) is, the bottom tazza is seldom or ever in keeping, as regards size, with the upper one; to remedy this it will be found a good plan to have zinc trays made of a size in keeping with the upper tazza; these trays should be about an inch and a half in depth, and painted green outside and white inside. The stand should then, after it has been screwed together, be placed in the tray, which, when packed with sand, will keep all perfectly firm; but should

March stand furnished with moveable top vase.

the stand, after being arranged, require to be moved from one table to another, it must be lifted by means of the zinc tray, and not the glass stem, which would be done were it not standing in such a tray. The next form which claims attention is the high single trumpet with three curved branches or trumpets arranged round the centre one. This stand is suitable for placing on a plateau of looking-glass, as it has no dish or tazza at the bottom; in my opinion, however, it is always improved by having some arrangement of flowers round the base, and, to effect this, it is a good plan to have a tray made similar in form to that just described, in which this description of stand can be quite as easily fixed as an ordinary March stand. My attention was first directed to this stand by Mr. W. Thomson, of Penge, whose taste in floral decorations is well-known, and I have since used it constantly at flower shows, and on our own dinner-table; it cannot, however, be arranged so quickly as the March stand, but a little practice will soon overcome that difficulty, and, when arranged, it forms a truly handsome centre-piece for the dinner-table. There is also a stand very similar to that just described, which has a tazza raised on a pedestal about 6 inches high, but, as this form is never made of as large a size as the first-mentioned, it is not so suitable for the decoration of a dinner-table,

but it nevertheless forms a very elegant drawing-room vase. A high slender trumpet, rising out of a flat tazza, is another form of vase which is well suited for the dinner-table. The next which I shall mention is the common March stand, perhaps the best known of any, and one which is to be found in almost every household where floral arrangements are attempted, though I must confess that I am not such an ardent admirer of this form of vase as most people; on the contrary, I much prefer, as I have stated, a March stand, with a trumpet rising out of the top tazza. Before concluding my

Compound trumpet-stand.

remarks on the forms of stands, &c., I must not forget to mention the trays for placing round the bases of plants which are brought through the dinner-table. These should be made of zinc, about 1½ inches in depth, painted green outside and white inside, and of the shape represented in the accompanying illustration. After having arranged the flowers in each half, they are placed round the base of the plant, and by a little adjustment of the foliage the points of junction can be quite concealed. In purchasing stands, the brightest and clearest looking should be selected. This is not, however, of so much

Tray for placing round the bases of plants.

importance in the case of the March form as in that of some others, inasmuch as the tazzas are filled with sand, but, where a trumpet or some such arrangement exists, transparency must be secured, as glass with flaws or marks on it would have a bad effect, and should be avoided. Another point worth remembrance, when purchasing stands, is to observe that those selected do not intercept the view across the table; for, no

matter how handsome the flowers may be, or how costly the vases in which they are arranged, if they interrupt the view, everybody seated at the table would, if they were consulted, have them removed.

Materials for Keeping Flowers Fresh.

As a rule these consist of clay, sand, Moss, and water. For flat tazzas or zinc trays, such as described for placing round the stems of plants brought through the table, sand or Moss should be selected; if the former, it should be Reigate or silver-sand, though any kind may be used; but, should any portion of it happen to be seen, yellow or common sand has an unsightly appearance. When the tazzas or trays have been filled with the sand, the latter should be wetted by means of a small watering pot, which should hold, say a pint or a quart of water, a fine rose being used for the purpose, and the sand should be watered until it is quite wet. The sand must not, however, be made too wet, as in that case the stems of the flowers will not stand upright or where placed. If Moss be selected, that sold by florists in bundles is the proper kind; but persons living in the country may obtain all they require in this way in the hedge-rows or woods. In the case of bought bundles, when opened out, all leaves or other rubbish should be removed and the Moss placed in a basket, and put under a water-tap, which should be allowed to run freely on it for some little time, so as to thoroughly clean it. When this has been done, the water should be pressed out of it, leaving just enough to keep the Moss damp and the stems of the flowers fresh. For filling the trumpets, spring water, if it can be obtained, is the best, but whatever kind of water is used, it should be perfectly clear, as any little floating impurities are unsightly. Were I asked "which is the best material in which to arrange flowers—sand or Moss?" I should reply, "one is about as good as the other. If the flowers are to last for any length of time, place their stems in Moss, but, if this is not important, then use sand in preference."

A. HASSARD.

THE MISTLETOE GROWING ON THE MISTLETOE.

SOME time last year we called at Old Conna, the residence of Mr. Phineas Riall, near Bray. Besides its situation and views there is always here something to be found to interest the lovers of trees and plants. On inspecting a fine specimen of Mistletoe growing on an old Apple tree in the garden, and laden with its translucent pearly berries, many bird-sown seeds of itself were observed to be attached to the parasite. Several of these had germinated, and had apparently firmly attached themselves by means of the sucker or rooting end to the branchlets of the mother plant; but in no case, then noticed, had the plumbeous or ascending portion taken a vertical direction or developed further growth.

Being much struck with the fact, then patent, of the young Mistletoe plants rooting (if one may so term the process) in the parent tissues, we determined to keep the matter in view, and at a future day see what further progress, if any, was made by these partially developed little embryos. We are free to confess, however, that we had but slender hope of finding them come to anything. With this object mainly in prospect, we called at Old Conna, in the early part of the present month, and almost our first steps were directed to our friend the Mistletoe. On examining it, the dream of double parasitism was at once dispelled. The germinating entities of last year had made no progress, and in almost every instance life was only manifest at the descending axis, the young plant having withered off at the opposite end. We had almost turned away inclined to smile at the idea we had for twelve months entertained when attention was directed to what appeared to be a sturdy young Mistletoe growing on one of the internodes of the parent plant. Closer inspection left no doubt about the fact. Here was a stout young plant firmly established, which counted two or more years since it raised its little head aloft, and was then about making its third set of leaves. After admiring this tiny, but to us at the time exceedingly interesting object, we proceeded to examine more closely the thicker or inner ramifications of the plant, and were rewarded by finding growing midway on one of the thickest and smoothest internodes a sturdy young plant three times the size of the preceding, full of health and vigour, with two principal bifurcations, four secondary branches, and five sets of its twin leaves, counting its age probably by some half dozen or more years. Here, then, we found, hitherto unnoticed, or, at all events, unrecorded fact of double parasitism.—*Irish Farmers' Gazette*.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

I THINK this institution receives more support from gardeners than, as at present constituted, it has a right to expect, and in a very few words I will tell you exactly what I mean. It is the gardener's first duty, as it is that of any other man, to make the best provision he can for his old age, and in subscribing to this institution I do not think he does so. For this reason I do not subscribe to its funds. I hold a tolerably good position, have fair wages, and could well afford to pay the annual subscription of a guinea, constituting membership. Supposing I become a member and pay my subscription for a number of years, I have no guarantee that I shall have any return for my investment. I may become old and unable to work, but it is quite a chance whether I shall obtain anything from the institution which in better days I had subscribed to annually. I do not think a man, in making provision for old age, is justified in investing his savings in anything of a speculative character, as is the case in subscribing to this institution. Supposing I subscribe, and on attaining the age of sixty I should be unable to earn a livelihood, I shall stand a chance of being elected; but it is just possible a period of several years may elapse between the time of my sending in an application and being elected, and in the meantime I may starve. I am well aware of the rule under which members of fifteen years' standing are placed on the pension list without election, but that affords but poor consolation, for as years roll on there is a likelihood of there being more subscribers applying for admission than there are vacancies. When this is the case, of what avail is it that you have subscribed fifteen years? You have to incur all the expense and anxiety of an election, and in the end, perhaps, be defeated by those who are no more deserving than yourself but are fortunate in having more influential friends. But, supposing I am selected without election, or in an election am placed at the head of the poll, what is the pension I receive? Why, a pittance of £16 per annum; and supposing my wife was to be left a widow, and to be placed on the pension list, she would receive the sum of £12. This is about 6s. 0½d. and 4s. 0½d. per week respectively. I would like to know what a man or woman who has been in tolerably comfortable circumstances can do with these pittances. We have been told that we ought to support the institution, and I would like you to tell us what a man can do with six shillings or a woman with four shillings a week. I have been trying my hand at it, and the only use I can see for it would be to pay the rent of a room or a small cottage in a rural district. Again, to be eligible for election, you must not have an income exceeding £30 per annum, and you must not be in receipt of parochial relief; so that in the latter case, if you have not a good reserve of friends able to support you when you make the first application, you must either renounce all claim upon the institution or go on the tramp and stand the chances of being committed as a rogue and a vagabond. This is the assistance afforded by the "noble institution" we gardeners are called upon to support, and it is for this we head gardeners are expected to subscribe our guineas and take the sixpences and the shillings from the men under us. The pensions are an insult to the craft, and you may depend upon it that, until the institution offers something more substantial than at present, it will not receive a very large amount of support from gardeners. We have to work too hard for our money to admit of its being invested in such an unremunerative manner. If the institution afforded substantial assistance, plenty of gardeners would soon become members, but at present it is not held in high favour in gardens and nurseries. Unless it does something better, I do not see that it is of much use; for a man can, by beginning at thirty, secure an annuity of 6s. per week, to commence when sixty, by paying £2 per annum into the post-office. An extra pound is thus paid every year. But in one case the annuity is certain, and belongs to the recipient as a right at the age specified, whether able to earn his livelihood or not. In the other case it is uncertain; and, to stand any chance of obtaining it, you must stir up your friends and make the unpleasant admission that you are in a destitute state. [This letter, signed by a "Head gardener," and published in the *Gardeners' Magazine*, points out some things which deserve consideration when gardeners are appealed to to support this institution, and the thoughts which it expresses in connection with it have often been our own. Independence is a sturdy hardy plant which we should like to see every gardener cultivating, as it is more likely to thrive to his satisfaction than such feeble reeds of charity and benevolence as are above referred to. We also hope that the institution may some day be modified in such a way as to afford gardeners sufficient encouragement to join it from the wholly independent point of view. It should aim at offering gardeners a sufficient support in old age, and that support should be the right of all those who had duly paid for it, without any kind of voting or pretence of pseudo-benevolence.—Ed.]

OLD LONDON GARDENS.

NOWHERE are gardens and shade-trees more welcome and enjoyable than in our large cities and open town spaces, and any diminution in their number, in order to give place to bricks and mortar, must be looked upon with regret. A garden an acre or more in extent, well planted and enlivened with sparkling water and brilliantly-tinted flowers, is a thing to be desired even in the most salubrious of neighbourhoods; but, when such a garden lies within a stone's throw of the Royal Exchange or Bank of England, in the very densest and most crowded part of London, it becomes so intimately associated with public welfare, that its loss would be a real calamity. In such a position is the Drapers' Company's garden at the present moment. Although it belongs to one of the wealthiest of all the ancient City guilds, it has been advertised as a site for building purposes; but whether this project will be ruthlessly carried out, and another of the historical landmarks and breathing-spaces of London be wrenched from us,

attractive features in the garden, if we except the shade trees, is the central piece of water just alluded to. In this the common white Water Lily grows and flowers as freely as if it had been set in a limpid stream, o'erhung by Willows far away in the country. Anacharis and Alisma plantago also grow freely here, and the former is just now bearing its singular pinkish-tinted flowers more profusely than we ever remember to have seen them elsewhere. Very little is done here in the way of cultivation; the garden, therefore, owes its charm principally to such shrubs, trees, and old-fashioned flowers as can take care of themselves. Among other open spaces in the City is the garden of the Mercer's Company, also close to the Bank. In this there are some fine old trees, and there is a little garden, gay with flowers and shrubs in the quadrangle court of the Bank itself. Nearly three centuries ago Lord Bacon penned his celebrated essay on "Gardens," in his chamber in Gray's Inn, where even now an avenue of Elms represents those which afforded shade to the witty philosopher

View in the Drapers' Company's Garden.

remains to be seen. The subject is now engrossing great attention, the space in question having been a garden as long ago as the reign of Henry the Eighth. Our illustration gives an excellent idea of the present appearance of this time-honoured breathing space, which only the other day was honoured by the presence of Royalty at a distribution of prizes given for the encouragement of one of the most pleasing of all decorative arts—window gardening in towns. The garden itself is oblong in shape, and comprises rather more than an acre of green turf, surrounded by shady walks. In the centre is a large pond well furnished with water-plants. Poplars, Maples, and other trees and shrubs, grow well here; and there are some fine old Pollard Mulberries just now remarkably fresh and green, and bearing abundance of fruit. This is one of the best of all comparatively dwarf trees for city gardens, and one which deserves to be more generally used by town planters than it is. Here these trees look as if they had stood for centuries. One of the most

who could appreciate a town garden even in those days, when fresh fields and villages were within half an hour's walk of St. Paul's. Many of the old City churchyards contain some fine trees; but we would also like to see them contain better flowers than Golden Rods and Sunflowers. These gloomy-looking old burial grounds might easily, we should think, be converted into beautiful gardens, full of flowering shrubs and sweet-scented blossoms, thus adding considerably to the beauty of such open City spaces. Finsbury Circus, Tower Hill, and the Temple represent good city gardens; and within the walls of the Charterhouse there is also a large open space, which, however, we fear will soon be built on, though invested with so many old memories and lasting associations. As for the difficulties of gardening in the City they are purely imaginary. Hitherto, no pains have been taken in the planting of trees, or no good preparation made, and yet we could enumerate a whole arboretum of trees and shrubs that are now in perfect health in City gardens.

GARDEN DESTROYERS.

SNAKE MILLIPEDS AND CENTIPEDES.

THE myriapoda, to which the above insects belong, are divided into two great sections, the most important character of which, so far as the horticulturist is concerned, is, that the one (with a curious exception, where the mandibles are converted into a sucking apparatus) has its jaws or mandibles formed on the ordinary plan adopted in insects that chew their food, while the other has them formed out of its fore-legs into something half-leg, half-jaw, after the fashion of the nippers of spiders, with a sharp point and a hollow duct up their core, which is connected with a poison gland, as is the case with, at least, some of the spiders also. The former of these sections compose the Chilognaths (meaning jaw-jawed insects) or Julidae, the latter the Chilopods (meaning foot-jawed insects) or Scolopendridæ. This difference in the character of their jaws is a very important one for the horticulturist, because by it he is ought to be able to distinguish between his friends and his enemies. The Julidae have their jaws perfectly adapted for chewing vegetables as well as any other matter. The Scolopendridæ have not; and the same principle that enabled Cuvier to determine the nature of his fossil vertebrates, whether carnivorous or herbivorous, equally applies to the organs of feeding in these insects. Both, to be sure, are equally under the ban of horticulturists, because both are found by them in injured roots of plants, and they credit both alike with the damage done, although the one actually did it or helped to do it, and the other only came there to prey upon the insects that were busy doing it. Curtis, although himself regarding the Scolopendras as carnivorous, mentions that the late Mr. Hope "attributed the Potato disease to the attacks of the wire-worm, and also to a small Scolopendra which he had found in myriads infesting diseased Potatoes at Southend," and Curtis adds that he himself "observed them in rotten Potatoes in August 1845; and in September 1848 *Geophalus electricus* was running about in every direction when the Potatoes were forked out." But an examination of the structure of their mouth and jaws, at once shows that the Scolopendridæ could never be vegetable feeders. There are two principles which it is safe to say Nature never deviates from. She never does anything without a purpose (although we may not always see it), and she never wastes her labour. If she endows an animal with any special structure or apparatus, it is for some end, and with the intention and for the purpose that the animal shall use it to attain that end. Now it is obvious that if the centipedes feed on the roots of plants, they must sin against both of the above principles in Nature's code. A poison bag and a poison tooth can be of no possible use to a herbivorous animal, therefore, as it would be a useless waste of apparatus to give it something which was of no use to it, the animal possessing these tools cannot have been intended to be herbivorous. The structure of the poison apparatus has been perfectly well ascertained, and the poisonous character of the secretion sufficiently proved by experience. As to the latter, De Geer, who was more practically acquainted with the habits of insects than almost any other naturalist of the last century, watched the proceedings of one species common in this country (*Lithobius forficatus*), and says of it, "I have seen a fly after being bitten by one of the Scolopendras die almost instantaneously, which would seem to indicate that their bite is venomous," and Latreille drew similar conclusions from his observations on another which is common in France and the South of Europe (*Scutigera araneoides*). The larger the species naturally the more powerful should the poison be expected to be, and the bite from one of them causes pain and suffering, even to man himself. Brown, in his "History of Jamaica," says of one of the larger species (*S. morsitans*)—"This insect is reckoned very venomous; the prongs of the forceps are very strong, bending and pointed, which enable them to bite very hard, and they probably emit some venomous juice also, as some who have been bit by them informed me that the part bitten is very painful for two or three hours, and turns frequently of a livid colour. I have seen them often kill a cockroach with a single nip." We also may cite an actual example of the severity of the bite related to us by the sufferer. He was the manager of a sugar plantation in

Jamaica in the bygone days, when slaves were still slaves, and Jamaica still Jamaica, and in the "boiling season," when the juice of the cane is boiled to produce the sugar, it was his duty or practice to visit the boilers during the night to see that the fires were kept up and no intermission allowed in the process. On these occasions he merely threw on a dressing gown and thrust his naked feet into slippers while he took a hasty round through the works. While thus engaged he was once bitten on the leg a little above the ankle by one of these large centipedes. They are nocturnal animals, and of course most lively and alert at night. He described the pain as so excruciating that he almost fainted on the spot, and had to be assisted into the house, and some time elapsed before he got the better of the bite. As to the structure of the apparatus for poisoning the wound made by the bite, that was satisfactorily made out by Mr. Newport, the eminent entomologist, whose loss is still deplored by our older naturalists. Until he worked it out, the gland by which the poison of the centipede is secreted had not been shown. Leewenhock discovered at the apex of the mandibles an orifice that communicated internally with an elongated cavity, and he also saw a drop of fluid exude from the orifice, but he did not discover the true secreting gland—which, however, Newport did. He not only confirmed Leewenhock's observation in regard to the existence of a longitudinal opening at the inner margin of the apex of the mandible, but also traced backwards a sac with which it communicates, and discovered the gland of which it is the reservoir. It is to be observed, that the effect of the bite of a centipede in warm climates is very various; sometimes excessively virulent and painful, at others causing little inconvenience. It is, no doubt, in a great measure due to the state of health and constitution of the individual sufferer and his consequent susceptibility to disease; but, moreover, from experiments on venomous snakes, we now well know that the virulence of the poison and the degree of injury inflicted by it, may depend much on the circumstance, whether or not the animal has recently bitten and expended its venom on some other object; in which case, the injury occasioned is less severe; and, the reason is obvious, not only may the reservoir of venom be exhausted, but it may also be satisfactorily accounted for by what we now know of the manner in which the secretions of all glands are elaborated by the growth, bursting, and diffuence of successive series of epithelial cells that line the interior of these organs, the fluid contained within, and into which these cells and their nucleoli are resolved being the proper secretion. When this is expended too frequently, and the organ in consequence is excited by what may be called the stimulus of want, the secreting epithelial cells are hastened in their development, and the fluid into which they are resolved is imperfectly elaborated and its properties are doubtless less active.

Another curious secretion, which is produced by one at least, if not more, of the Scolopendridæ is a sort of phosphorescent light, which seems to exude from the body, and is left like a shining trail on the spots over which the insect has passed. It soon fades and disappears, seldom being seen for a longer space than a couple of feet behind the insect. *Geophilus longicornis* is the species whose luminosity has been most frequently observed in Britain, but there are reasons for believing that the property is common to all the section of centipedes known as Geophilidæ, and that it is evolved only at the breeding season. Mr. Newport mentions having found two individuals of this species on the ground in contact with each other at midnight, on the 25th of September, which shone almost as brightly as the glow-worm, for which, at the instant, he mistook them. On taking them into his hand the luminous matter was exuded and adhered to his fingers, and continued to shine for some time, like phosphorus. The individuals appeared to be able to give it forth at pleasure. This property appears to be common to some tropical, as well as European, Geophilidæ. Oviedo, the friend and companion of Columbus, as quoted by Newport, mentions it in his account of the island of St. Domingo:—"There are in this island (St. Domingo) many kinds of Scolopendra or hundred legs; some are slender, and as long as one's finger, and like to those of Spain, and these bite and cause considerable pain. There are others of these worms about half the length of the finger and slender,

with many feet, and these shine much by night, and leave a light where they go, and may be seen 50 or even 100 feet off. Yet the whole animal does not shine, but only the joints where the legs spring from the body, and the light is very bright."

The horticulturist must regard all these centipedes as friends, but not so with the snake millipeds or Juli. These are general feeders, consuming both living and dead, and decaying animal and vegetable substances. The living animal matter on which they prey is slugs, small snails, earthworms, insects, and their larvæ and pupæ, and so far as that goes they may be regarded as friendly to the cultivator; but, on the other hand, they also feed on living plants, and many of them, such as Potatoes, Carrots, &c., are often seriously injured by their attacking their roots. It is a question, however, whether they are not sometimes unjustly blamed. They are, undoubtedly, often found in holes in our root crops, but it may be that the holes were already there before they came, and that they have only come to feed on the soft parts of a diseased or decaying root. A sound healthy tuber has, perhaps, too tough a coat for them to penetrate, but when they get into the juicy interior of soft pulpy roots, such as bulbs, the case is different; they can have no difficulty in making their way into them or in consuming the tender fibres of the roots of herbaceous plants.

It is very doubtful whether any means have been found of getting rid of these insects. Sprinkling soot and nitrate of soda over the land and watering it with lime water have been recommended, but apparently without much success. It is difficult to damage the insect without damaging the plant it is attacking too. So far as greenhouses, hothouses, and out-houses are concerned, they may be kept tolerably free from them by care, cleanliness, and the adoption of such traps as have been already referred to in Mr. Baines' and other papers in this journal; but the open fields are less under control. The commonest species are the *Julus terrestris*, a leaden-coloured species, something like a thickish wire, and *Julus guttatus*, a small long thread-like species, too minute and slender to allow anything to be done by direct manipulation. When viewed under a magnifying-glass this last species will be seen to be a very pretty little animal, like a pale thread about the thickness of a pin, with a double row of bright crimson spots on it, and when put in spirits it stains the liquid of a purple hue, to which it itself turns after death. It has no eyes, which has led to its being regarded as belonging to another genus. This is the species which most frequently forces itself upon the attention of horticulturists, and Lilies seem especially the object of its attacks. I, sometime since, received from Mr. George F. Wilson, F.R.S. (and placed in the collection of economic entomology now at Bethnal Green), preserved in glycerine, the scales of the bulb of one of his Lilies which was disintegrated by these little creatures, and a correspondent of this journal, not long ago, stated that on turning out some pots of *Eucharis amazonica* and *Vallota*, which were not thriving, he found, besides acari, a quantity of this species of snake milliped busy about the roots. Further investigation showed that the roots of some of the sickly plants had been perforated by these insects, which had also eaten their way into the body of the bulbs themselves. Curtis, from his own knowledge, specifies the roots of the Scarlet Runner, the roots of the Cabbage tribe generally, and the roots of young Wheat, as having been attacked, and Mr. Wilson Saunders, who, we all know, is not a man likely to be deceived in any point relating to horticulture or entomology, notes that he had observed that the young roots of his Heart's-ease were injured by this species.

There are several other British species of *Julus*, viz., *J. Londinensis*, *J. latestriatus*, *J. punctatus*, and *J. pilosus*, and along with them should be reckoned the little flat *Polydesmus complanatus*, which seems to be not far behind *J. guttatus* in its mischievous propensities.

A. M.

Mealy Bug on Stephanotis.—I should esteem it a favour if you could inform me how I can effectually remove mealy bug from a house devoted to Stephanotis. The house is 12 feet square, and covered with Stephanotis.—ROBT. JAMES. [Reply by Mr. Baines:—It is difficult to completely eradicate mealy bug when once it has got established, but, with perseverance, it can, nevertheless, be accomplished; and it is more easily destroyed on Stephanotis than on

most other plants, owing to its being able to bear, without injury, an application of "insecticide" sufficiently strong to kill the insects. Remove the plant from the wires, and immerse its head in Stevenson's "Abyssinian mixture," 8 ounces to the gallon; repeat this two or three times in the course of a fortnight. Paint the house thoroughly; limewash the walls; remove the surface soil from the beds, if any; also tan, or other plunging material; in short, leave no lurking places in which the insects or their eggs can find a lodgment. Dip and wash all plants in the "insecticide" repeatedly, as advised in the article devoted to this insect (see the last volume of THE GARDEN, page 141). This, if carried out, will effect its complete destruction.]

Rainfall in North Leicestershire.—In horticultural, as well as in other affairs, there is always a degree of consolation experienced when great cultural misfortunes are shared by the whole community. Individual and exceptional troubles from ungenial weather are rare, but when they do occur they seem to press with particular force on the unlucky sufferer. In the matter of rainfall I am made painfully conscious of being in a peculiarly unfortunate and exceptional position, without having enjoyed the advantages of a shower, in quantity more than enough to lay the dust, for nearly three months past. I read in the papers that refreshing rains have fallen in the north; your correspondent, Mr. Barnes, reports heavy showers in the south. West of this place thunder-storms and copious rains have filled the brooks and replenished reservoirs; and lastly, news comes from the dry east that rain has fallen in sufficient quantity to re-invigorate the languishing Roses. Above the river system of the country, uninfluenced by the east or west coast evaporation, near the very centre of the island, I find that at Belvoir, climatic circumstances exist, which, though sometimes satisfactory, are, in a season like this, painfully trying. The rainfall for 1873 for this district was $4\frac{1}{2}$ inches below its average amount, and every month of the present year has exhibited a deficiency. We registered in January 1.58, February 1.59, March 1.05, April 1.11, May 0.97, June 0.35, July 0.07; up to the 17th the total registered amount is 6.75 for a period of six and a half months. The above figures will at once tell rainfall observers the state of dryness to which we have been subjected. The temperature of the earth has increased considerably; a wine merchant at Grantham informed me that his cellar, which for twenty years had never exceeded 53°, had this year increased to 62°. Large and deeply-rooted fruit trees are so far affected as to lose a portion of their fruit. Hay has been cut one day and carried the next. There exists no present chance of securing a Turnip crop; late planted Potatoes have dwindled and failed; succession Pea crops languish for moisture; and watering alone keeps vegetable crops from dying up. The catalogue of troubles and trials to which we, in this little central portion in North Leicestershire, are subjected by the prolonged drought might be indefinitely extended, but quite enough has been told to establish my position—that we are in a dry and stormless region.—WILLIAM INGRAM.

The Heat and Drought.—These have been indeed serious, but let us hope that the worst is over. On July the 20th the thermometer stood at 90° in the shade; Apples were roasting on the trees, as were also Plums and Apricots, and Strawberries and Raspberries were being burnt up. Cauliflowers were drained of sweetness, and Lettuces were driven into seed-bearing by the fierceness of the sun's heat. St. Swithin, as Mr. Ingram, of Belvoir, humourously put it, has done nothing for us, and we ought to have appealed to St. Phœbe to have prevented our gardens being converted into herbariums. Such a deficiency of rain and excess of heat coming together have been most disastrous. Two lessons have, however, been taught us: One is the importance of deep cultivation; and the other is a better and larger means of storing water—or, in other words, to prepare for the drought. Store more water in the earth and out of it—the former by deep tith, the latter by larger tanks and deeper cisterns or wells. The expense of carting water on many estates now is one of the heaviest. The water is also often bad and dirty, and farmers and gardeners are haunted with the fear of the pond and well becoming dry. All this trouble might be averted by a larger storage of rain and other water. Deep tith, again, carries the crops through even such seasons as these, whereas, on shallow ground, the crops droop, and fail, and absolutely die by wholesale, for lack of water. Peas, on shallow land, this year are an absolute failure, seldom returning the labour, to say nothing of paying back the seed sown. On deeper tith they stand, and will yield half a crop. To carry on gardening without abundance of water is impossible. Water is the chief constituent of fruit and vegetables, the basis of sweetness of flavour, and tenderness of flesh in both; and everywhere the parched plants and trees are now pleading, with bended stems and flagging leaves, for water.—D. T. FISK.

THE KITCHEN GARDEN.

CUCUMBER CULTURE ROUND LONDON.

THIS is one of the most extensively grown indoor crops in market gardens, some growers devoting immense ranges of glass houses to its cultivation, while others grow it very largely in frames on sunk hot-beds. Some idea of the extent of its culture may be obtained from the fact that Mr. George Steel, of Fulham, has, annually, a field of frame-ground containing many ranges of frames with from 800 to 1,000 ordinary sashes; other market gardeners grow in proportion. From this field Mr. Steel sends to market weekly, during the summer, from 180 to 220 dozen of fruits. At one time Cucumbers were extensively grown out-of-doors in the market gardens round London: but for the last thirty years this practice has been abandoned. In the neighbourhood of Sandy, in Bedfordshire, however, they are yet grown on a large scale out-of-doors on ridges. Mr. Wm. Bagley, of Fulham Fields, has still the same variety of Cucumber growing in frames that his father used to grow out-of-doors forty years ago. The Telegraph, and varieties of it, are much grown in frames; so is the Syon House, Pettie's, and a few other sorts. These kind, together with the Rabley, Duke of Edinburgh (some excellent gardeners say that the Duke of Edinburgh is a good variety of the Rabley), the Hedsor (Mr. Murray, of Frogmore, informs me that the Hedsor is a tried and select form of the Telegraph), Sutton's Perfection, and a few others, are chiefly used for growing in span-roofed and lean-to pits or houses. For framework, the first sowing is made in little punnets or flower-pots, which are placed in hot-dung frames. When they germinate and are fit for potting-off, two plants are potted into a 6-inch pot, and the whole replaced again in the frames, keeping them near the glass. About the middle of February or in March, just as soon as some of the frames can be emptied of the Cauliflower or Lettuce plants that were wintered in them, the frames are moved aside, and trenches cast out 5 feet wide and 2 feet deep, and firmly filled with once or twice-turned stable litter. Over this some soil is placed, and the frames set on again. The earth that was cast out of the trenches almost levels up the space between the frames. When the heat subsides enough to permit of planting, a little more soil is introduced to the frames, and one potful (containing two plants) is planted under each sash, and one of the plants is trained towards the front of the frame, and the other towards the back. The sashes are then put on, and all is kept close for a few days, and, if need be, a little shading is also given by strewing some litter over the glass. Afterwards, until the plants have fairly begun to grow, no more ventilation is given than is necessary to prevent scorching in the case of bright sunshine. Another sowing is generally made to succeed the first one; but, as a rule, there are seldom more than two sowings made, and the second is only sown because all the frames would not be empty at one time, to be filled by the first sowing. Where great pains is taken the earliest plants retain their good bearing qualities as long as the latest sown ones. For several weeks after having been planted, they are protected at night by covering the sashes with litter, removing it next morning; indeed, this covering is not discontinued until the month of June.

When the plants have grown sufficiently to come into bloom, they are most attentively looked after in the way of regulating the growths, pegging down the vines, stopping the shoots at the joint beyond the embryo fruit, and in preventing an accumulation of superfluous growths. Throughout the day they are allowed to have plenty of air during the summer, but it is all taken off at night. As soon as the men come in the morning they tilt up the sashes a little, and if the heat of the day greatly increases, the sashes are tilted up a little higher still, usually about 3 inches. Watering is performed in the morning, and is given abundantly to those requiring it, whilst those that are not dry have simply a sprinkling overhead. In watering, one or more men are employed in carrying the water to one who pours it on. It is cold water from the tap that is entirely used, and I think that this is the greatest drawback to Cucumber growing that the market gardener has to contend with, as where one or several acres are covered with frames for this fruit, it would be next to impossible to make

tepid all the water required. Large hogsheads, however, are sunk here and there about the frame ground, and brick or cement tanks are frequently used for containing water, with which they are filled for the next day's use. Manure-water, made from guano, is sometimes given during the summer time, being applied through a fine rose overhead. This application is not only useful as a stimulant, but Mr. Hubbard, foreman to Mr. Bagley, of Turnham Green, assures me that he has found this manure-watering, when given overhead, to be of material benefit in destroying or preventing red spider as well as invigorating old plants. In reference to woodlice, Mr. Hubbard also informed me that he gives considerable sums for toads to people who fetch them chiefly from the neighbourhood of Wimbledon and Kingston. A couple of men are commonly kept at work in the frame ground, and on three days of the week (Monday, Wednesday, and Friday) they are employed in cutting fruits for market, and on the other three week days they are busy stopping and regulating the Vines. Should any young fruits exhibit a tendency to become crooked, they are put into cylindrical glasses open at both ends. These glasses are about a foot or fifteen inches long, and one and a half or two inches in diameter, and several thousands of them are employed in one large frame-ground, as one good and straight fruit is worth nearly a dozen small and deformed ones. The best of the crooked ones do for pickling. Cucumbers require sunny weather to set well, and in dull wet seasons they do not do much good, especially in the earlier part of the year. Should the summer be hot and bright, the sashes must be shaded a little, and this is done by strewing some rank litter over the glass; but many market gardeners, by way of economy of labour, paint the sashes with whiting, as in the case of glass houses.

By the 1st of August the plants will be getting exhausted; therefore careful attention is paid to thinning out old and bare vines, and encouraging young wood by means of stimulants, in the way of manure-water and coverings from cold; and in this way they will last good till September. In August some fruits are saved for seed, for if left sooner they would materially weaken the crop of marketable fruit. Should any "nosed" fruits be detected, these are sure to be taken care of, tied round with a string, and left till ripe, as they are certain to contain good seed. When the seed fruits become yellow and are cut, they are placed under sashes or on boards before the sun, so as to get thoroughly ripe and hard before being separated from the pulp. F.

TURNIPS FOR WINTER.

THE winter crop of Turnips is the most important of the year. Cooks prefer their Turnips off the ground, and not from the store heap, and it is necessary to sow a good breadth for the winter supply. Chirk Castle is the best variety with which I am acquainted for winter use, as it is very hardy, and as regards flavour and appearance among the best, being white and tender, though almost black outside. The date at which it should be sown for the winter crop must depend entirely on locality. Large Turnips are not wanted for culinary purposes; they should, therefore, be sown just soon enough to ensure their forming nice useable roots, about 4 or 5 inches in diameter. In the north, or in late districts, such a crop should be sown between the middle and end of June, but, in the south, sowing may be delayed till the beginning or middle of July. It is a good plan, however, to sow twice, or to sow also on a north border at the same time that a sowing is made in the open quarter. Turnips may follow early Peas, or any other crop not belonging to the tap-rooted section, for which the ground has been previously well manured. It is needless almost to say that the ground must be deeply and well broken up, and the Turnips should be sown as soon as the ground is ready, in rows 2 feet apart. When they have made their rough leaves they should be thinned out from 20 to 24 inches apart at least. This is wider than would be necessary for early Turnips, but, in winter, room between the plants is half the secret of success. When crowded, the leaves are soft and incapable of resisting frost; on the contrary they perish as soon as severe weather sets in, leaving the roots exposed, and as the latter are soft and watery, in consequence of the crowded state of the leaves preventing a free admission of air about them, the alternate frosts and rains of winter soon destroy them. When thus thinned, both roots and leaves attain a degree of hardness that enables them to withstand winters of a very severe character.

J. W. S.

THE ARBORETUM.

THE TULIP TREE.

(LIRIODENDRON TULIPEFERUM.)

THIS noble North American tree deserves a place on every lawn, as it seldom fails to develop itself into a stately specimen in any good, deep, well-drained soil. In habit of growth it closely resembles the common Maple, but its conspicuous orange-tinted blossoms and scaly fruits at once suggest its near affinity to Magnoliads, to which it belongs. The flowers are not unlike those of a Tulip, and hence the name by which it is most generally known. The broadly-expanded leaves, instead of being palmate as in the Plane, are irregularly four-lobed, and somewhat resemble a saddle in conformation; in the United States, indeed, the vernacular name Saddle tree is derived from this peculiarity, just as we derive our popular name from its Tulip-like flowers. Our illustration gives an excellent idea of the flowers, foliage, and fruit. The flowers are profusely borne during the summer months; and, although not strikingly ornamental on the tree on account of their being somewhat hidden amid the ample foliage, when cut, and arranged in a vase with the foliage that naturally belongs to them, they have a distinct and striking appearance. In America this tree is said to form specimens from 100 to 150 feet in height, but in this country it rarely exceeds 70 or 80 feet. There are some fine specimens at Fulham Palace, in the Royal Gardens, Kew, and in other places, although well-grown trees of it are by no means common. In the old arboretum at Chiswick, there used to be two specimens of this fine tree, one having much larger and brighter coloured flowers than the other; and, doubtless, other varieties of it exist where plants are raised from seeds. All through the summer the foliage is of a fresh pale green; and, in the autumn, it dies off a brilliant golden-yellow. Striking effects might, therefore, be obtained by grouping it with *Quercus coccinea* or the purple-leaved Beech. In addition to its ornamental properties, it is valuable as a timber tree, the wood being firm in texture and capable of taking a fine polish. It is, however, most valuable in this country as an ornamental tree, and, for that purpose, its distinct and noble port commends it at once to the notice of intending planters. In London gardens, where the tree flowers very well and grows fairly, the foliage dying off in autumn affords very striking effects. Its value is more apparent where stately specimens are found.

ON PRUNING FOREST TREES.

By ROBERT PHILIP, Forester to John I. Chalmers, Esq., of Aldbar.

I BELIEVE there is not a branch of the forester's work on which more diversity of opinion exists than on pruning forest trees; nor is there any one operation in the cultivation of timber which foresters seem so determined to conduct on the old principle as pruning. It is lamentable to see fine healthy trees, young and old, spoiled in their timber and retarded in their growth, by the way in which they are treated in too many instances. The great diversity of opinion on pruning which exists among practical men, has had a most prejudicial effect on the minds of proprietors of plantations; for those who have

taken an interest in the management of their woods have been bewildered by these opinions, when they turned their minds to the improvement of them. One writer advises to prune none, designating it as an unnatural operation; another holds pruning to be everything in the management of wood; while a third would prune so long as he can do so by merely pinching off the terminal buds with his finger and thumb. One writer recommends close pruning; another foreshortening; while a third recommends foreshortening, thinning out, and cutting close off from the bole all the branches which appear to be robbing the main stem of its due nourishment. It is little wonder that gentlemen have turned away from the subject in bewilderment, some leaving the matter in the hands of their forester; while others, afraid to risk the spoiling of their trees under such unsettled principles, have refused to have them pruned at all. This is how the matter stands with some of those who have turned their attention to the subject; but I fear too many have taken no interest in the matter at all; and until gentlemen do take an interest in all the branches of the forester's operations, arboriculture will never reach to that elevated position which it ought deservedly to hold among the economic sciences. Books, essays, reports, &c., have been written and published on pruning; but seeing that so much diversity of opinion exists, which has produced a baneful effect, instead of

Flowers, foliage, and fruit of the Tulip tree (*Liriodendron tulipifera*).

realising the object aimed at, we must look in some other direction for improvement. I should say, seeing that we cannot agree in theory and practice on pruning, let the plantations under the charge of the writer be examined, and if he has had full scope to carry out the theory or practice which he recommends in his writings, then it could be possible to judge of its merits; and let it be reported on by the judges, who ought themselves to be intelligent, practical men of experience. By this, or some such method, a knowledge of the system of pruning which will produce the cleanest and soundest timber, may be attained at once, and prevent that delay which must necessarily be submitted to before it can be tried and the result ascertained, to say nothing of the risk of destroying good trees by pruning on a wrong principle. Until some such plan of ascertaining the best system be adopted, I fear all the

essays and books which can be written on the subject will tend little more to settle the matter than what has been already produced. I shall now proceed to give my own method of pruning, and its results.

Nearly thirteen years ago I was sent to prune a quantity of young Oaks and other trees, which were from 3 to 4 feet high, and had been planted a number of years. These trees were very unhealthy, from some cause unknown to me; for they were planted in good soil and situation, but they were literal bushes without any leader, and covered over with dead spray. I looked at the plants, going through them and examining them, and was fairly at a loss to know what to do with them. However, I commenced to cut off all the dead spray, and select the shoot most suitable for a leader to the plant; I then cut in or foreshortened all the rest of the contending branches. In this way I went over the plants and left them; and the first year after being so treated, they pushed out fine healthy young shoots, and formed good leaders. They have been two or three times pruned since, but slightly, as they were intended to keep thin on the ground. The ground on which part of them grows was afterwards enclosed as a poultry-yard, and this has been in their favour no doubt; but independently of the ground being kept clean by the poultry, the first pruning had a most beneficial effect upon them, for the ground was not enclosed for some time after it took place, and now they are as healthy trees as could be wished, but will never make clean timber, from not being regularly pruned, which was the wish of the proprietor. Almost the whole Oak and other hardwood trees on this estate have been very much neglected, both as regards pruning and thinning, when young; for many years, and, until the time I have mentioned, no pruning or anything like rational principles had been performed.

I have found, on cutting up hardwood of from eighty to a hundred years of age, that it had been close pruned at one period of its growth; and the Beech trees, in particular, have been very much damaged by the way in which the work had been performed. They had been pruned close to the stem, and a large number of branches taken away at once; for I have seen a plank with a large number of black decayed marks in it, not more than half an inch to 1½ inch in diameter; and the same thing is to be found in every other species of hardwood tree when cut up. But there is one exception, in the case of the Scotch Fir which had been served in the same manner; not one of them which had been pruned have left decayed holes in the tree, but the reverse; the wound has healed over, and fine clean wood has formed, leaving the knot fast in the plank when sawn up for use. Much has been written in favour of and against the pruning of Scotch Fir, but from what effects of it I have seen, I am satisfied that it preserves clean sound timber, nor could I detect any injury done to the growth of the tree; the concentric rings or annual growths were as large after the pruning as they had been previous to it, taking the slower growths of the tree naturally, as it becomes older, into account. I am of opinion that all dead wood ought to be pruned off trees wherever it occurs. In the case of some acres of Larch trees which had a large quantity of dead branches on the lower part of the trees, I knocked them all off as high up as a man could reach with the handle of his axe, and this has proved of great benefit to the health of the trees. I by no means recommend cutting off close to the tree green branches of any of the Pine tribe; but, if it were not for the expense of the process, I would prune off every dead branch as soon as I observed it dead. I have shortened branches on Fir, Spruce, &c., and have seen no bad effects follow: this is absolutely necessary in the case of nurses to hardwood. Pruning hardwood trees is an operation which I consider indispensable, if we would have sound clean timber. It too frequently happens that we have to deal with neglected trees, and there is a stage at which trees may have arrived, when pruning to any extent would be useless. The time which I consider trees ought to have their first pruning, after being planted where they are to remain, is, when they show proof that they have established themselves in the soil, and not till then, for I have never found any benefit to the plant arising from pruning before this time. Trees pruned when they have not established themselves are apt to push out young wood; but it rarely happens, in this quarter at least, that the young wood ripens properly; and the frost and cutting winds in winter kill back a great portion of it, and when young wood is killed back, it is, in my opinion, a means of rendering the plant unhealthy for a time, which retards rather than facilitates its growth. I never cut any of the branches close for a considerable time, and never cut any close but those next the bottom of the tree. I have ample proof of the bad effects of thinning out branches on a tree, for those left just grow the faster from having more light, air, and nourishment. I shorten all contending branches, or those that appear to be appropriating too much of the substance which ought to be deposited on the main stem, but keep all those which keep within proper bounds,

and by this method the strong branches are checked; for shortening, if not carried too far, will check the strong branches, as I have ample proof. If I find a strong branch with lateral shoots or spray upon it, I cut back the branch to some of the smaller branches, and endeavour to leave as little appearance of pruning as possible. When the trees are large and neglected, it is impossible to do this; but I prune very little off trees after they arrive at this stage; all I consider necessary to be done to them is to balance their tops, and preserve one leading shoot if the tree is not at the height required; and this is done on the foreshortening principle, but by cutting the branches at a greater distance from the bole, and only such of them as are straggling, and liable to be broken by storms. Many fine trees are destroyed for want of a few of these straggling branches being shortened. I make no difference in my mode of operations when pruning for timber, my aim being to produce as much sound clean timber in each tree as the nature of the soil, situation, and climate, will permit; and this applies equally to all kinds of hardwood. I do not find it necessary to prune oftener than once in two years, except the young trees—that is, till they are beyond reach of the pocket-knife—these I endeavour to have pruned every year; but pruning, if too frequently or too severely applied, will prove hurtful to the tree. It is not uncommon for healthy trees, the first year after pruning, to push up 3 to 5 feet of a leading shoot, and when so much growth is produced in one year, the tree makes little or no progress to height the following season, but furnishes the previous year's shoot with side branches. Some pruners evidently believe that a tree will produce timber as fast with few branches as with many, from the way they treat their trees, some thinning out the branches, others cutting away a large number of them close to the stem at one operation; but I always endeavour, by shortening, to keep the branches as small in circumference as I can, and have plenty of them; and if I thin any, it is for the purpose of checking the strong branches, and may cut them further back than the ordinary outline of the tree, and by this means the wounds are in a great measure hid. By this system of pruning I have Oaks 30 feet and upwards in height, and no branches on them more than 2½ inches in diameter at their base, and few of them so thick. These trees have not been so regularly pruned as I could have wished, but they show what a little assistance will do for them. I have no particular proportion of head to the stem, but find that trees increase in thickness fastest when they have about two-thirds of their whole height covered with branches during the whole period that they are increasing in height, but ought to diminish to between one-half and one-third of the height for a top, according to the sheltered or exposed situation they may be in, care being taken not to draw them up too fast, and then allow them to get top-heavy, as this would bring on too much strain both on root and stem; and this in soft soils is very injurious to the tree. Every tree has its own habit; and the pruner must, in a great measure, adapt himself to the habit of the tree he has to deal with, and not force them into any shape which may please the fancy of the operator. We can only assist Nature in her operations, and if we would study her operations more closely than we do, there is no doubt but we would arrive sooner at practical conclusions. One tree, such as the Poplar, has a natural tendency to keep to one leading shoot, and to keep its branches within a comparatively narrow space; while the Oak has the opposite tendency if left to Nature; its habit is to have a short stem with a wide-spreading top, which may be a beautiful object in certain situations, but certainly not profitable as a timber tree. Pruning is so closely connected with, and dependent on, judicious thinning, that attention to it is of great consequence; for to thin the trees to wide distances will cause them to throw out strong side-branches, and creates additional work to the pruner; but by keeping the trees pretty thick on the ground, the branches are confined within reasonable limits, and consequently kept from increasing to a large size. The method which I adopt is, by thinning and pruning, to keep the trees standing quite clear of each other, to allow free circulation of air, and admit the light all round them, both of which are essential agents in the growth of trees; and by this means I manage to keep the trees in a healthy growing state, and prevent the branches from becoming large, which always detracts from the value of timber, except where bends and "knees" are formed fit for shipbuilding; and I fear there are too many of these gnarled, ugly trees in this country at the present day, which, if left alone, as they are past much assistance from the pruner, will keep plenty of them in the country, without allowing the young trees to be lost in the same way for a considerable time to come. The tools which I use in the operation of pruning are a strong pocket-knife, handsaw, a saw with the teeth reversed, and the pruning-shears; the last two are fixed on long poles, and they save much loss of time in climbing; for trees farther advanced a ladder 14 to 18 feet will be found necessary.—*Transactions of the Scottish Arboricultural Society.*

FRUIT CROPS IN SCOTLAND.

Roxburghshire.—Floors Castle, Kelso.—The fruit crop in this neighbourhood is, on the whole, a fair one, notwithstanding the very unpropitious weather which we had in the early part of the year. The only exception is the Apple (in some districts, and with me), which is very poor. Some of the trees, however, such as Atkins's No. 1 and Ecklinville, are producing a fair crop. Apricots on south walls are laden with fruit, which promise to be fine in quality; the Breda is approaching maturity, but is small, a fault made up by its earliness. Our Apricot trees were only protected with Silver Fir branches; as the growth advanced, the leaves of the Fir dropped off, giving light and air gradually; this is, I think, the best of all kinds of protection of a temporary character. I have tried all other schemes of covering, but none beats this as regards simplicity and effectiveness; and, at the same time, it is cheap and procurable in most places. Spruce Fir is nearly as good, but the branches do not lie so closely and snugly on the trees. Plums were protected in the same way on south walls; but on north walls, where we have our Golden Drop, and from which we get a supply till the end of November, we do not protect at all, as the trees flower sufficiently late to be out of the reach of frost; hence, I think walls of this aspect should be planted with other fruits besides Morello Cherries. Plums on walls are an excellent crop, and standards of Victoria are laden with fruit. Damsons, again, are fruitless, owing, no doubt, to their early flowering and the frozen ordeal which they underwent. Strawberries have been very plentiful and fine; but, as I think, wanting in flavour. The kinds which suit us best are Keen's Seedling, President, Prince of Wales, and La Constante, and these form our indoor supply as well. New plantations are made from those fruited indoors every year; the year after they yield large crops, and frequently a sprinkling the current year in autumn. Currants and Gooseberries are only a middling crop, fully half of the crop having dropped in consequence of frost. We are very much exposed to north-west winds, which, however, we are endeavouring to shut out by means of young wood plantations. I attribute the loss of our crop of Apricots on a west wall to this exposure. The east side of this wall is covered with Ivy, and I am training the Ivy over the top, and am in hopes of forming a natural coping for the trees on the west by simply stretching a wire along to support the ends of the Ivy, allowing it to hang down here and there along the front. The good old dwarf Raspberry called Northumberland Fillbasket is a never-failing crop. Morello Cherries are abundant, as they always are; but table kinds are scanty and not good. We have no outdoor Peaches or Nectarines, but those indoors are, and have been, plentiful and fine, especially Nectarines, which are really more useful in every way than Peaches, as they carry better and keep longer after being ripe. Had we more Apples, our supply of fruit would have been, on the whole, satisfactory.—HENRY KNIGHT.

Midlothian, Dalkeith Park.—Apples here are a moderate crop; the cold easterly winds which prevailed while they were in flower considerably thinned them; the trees are clean and healthy, and such fruit as they are bearing of good size and quality; Pears, an average crop, both on walls and standards, and the fruit being free from spot and of a fair size has a fine appearance; Peaches and Nectarines on the open walls are hardly an average crop, and the leaves are suffering from blister and aphides; Apricots are fully an average crop; Plums and Morello Cherries, a moderate crop, but the trees suffered much from aphides during the dry weather in June; Strawberries, Raspberries, and Currants, a good average crop; Gooseberries, a partial crop and very much infested with aphides; Filberts and other Nuts a light crop. On the whole, this may be considered to be a fair average fruit season in this locality. We almost entirely escaped the severe spring frosts that played such havoc amongst the fruit in other districts.—M. DUNN.

Oxenford Castle, Dalkeith.—Apples here are a good average crop—Lord Suffield, Ecklinville, and Oslin, being heavily laden, but in the case of some kinds the fruit is dropping a good deal; Apricots are a heavy crop, though three-fourths were thinned off; the fruit is swelling off satisfactory, the borders having been mulched all the season; sweet Cherries are under the average, best on west aspects; Morello kinds are very heavy, the fruit is, however, ripening prematurely, and is, in many cases, dropping off; Currants, red, an average crop; white, good; black, medium, fruit not so large as usual; Gooseberries are so heavy a crop that the bushes have required propping up, and the fruit is large and fine; Plums (Green-gage section) under average; Victoria, heavy, both on walls and standards; Damson (Scotch), very heavy; Pears are a fine crop, healthy, and swelling well on walls, the borders of which have been mulched, Hessel and Croft Castle also good as standards; Raspberries, rather under the average, foliage browned as if burned, and fruit under the usual size; although the ground was mulched, I

presume last year's wood was unripe; Strawberries here on heavy soil, a very heavy crop, but where the soil is light a poor crop; and the plants are suffering from drought; the varieties grown here consist chiefly of Keen's Seedling, Prince of Wales (Ingram's), La Constante, Viscountesse Hericart de Thury, British Queen, and Duke of Edinburgh (Moffats). Some things are suffering a good deal from want of rain, but, in general, our fruit crops are satisfactory. Our soil being a strong heavy loam, or nearly clay, resting on 40 feet of blue clay, does best under a roasting season. Our practice is to mulch extensively and never to dig amongst our fruit trees, bushes, or Strawberries. Some growers for market, in this neighbourhood, on lightish land, have very poor crops, especially Strawberries, which are rather a speciality in this locality.—A. ANDERSON.

Renfrewshire.—Blythswood.—Round this neighbourhood, Apples and Pears, though a fair crop, are nothing compared with what was expected from them when in bloom. The withering winds in May so checked the trees, that three-fourths of the blossoms failed to set, and in many cases half of those which did set, have since dropped. Strawberry crops are plentiful and fine—indeed, all small fruits are abundant; the Gooseberry caterpillar, however, has caused more annoyance in some places than has been the case for the last year or two. Outdoor Peaches are nearly a failure, though they flowered profusely; Apricots are better than usual; Plums, with the exception of Victoria, are very scarce; and Cherries, with the exception of Morellos, are also a thin crop. Among Apples, Lord Suffield and Stirling Castle, are bearing exceptionally heavy crops; Strawberries are fine, and Gooseberries abundant; Currants are plentiful and clean, which was far from being the case here these last two years; Raspberries are also fine, having been much benefited by the late rains. I may add, that Apricots are never a satisfactory crop out of doors in this neighbourhood, owing, I believe, to the atmosphere being so damp; but Peaches, until the last two seasons, have been abundant, and have ripened admirably.—JOHN METHVEN.

Dumfriesshire.—Drumlanrig.—The fruit crops in this district may be set down as follows:—Apples, Plums, and Cherries, plentiful; Pears, average crop; Peaches, moderate; Gooseberries, Currants, Raspberries, and Strawberries, heavy crops and fine in quality. This season is considered to be the driest and warmest which we have had since 1826.—DAVID THOMSON.

Perthshire.—Drummond Castle, Crieff.—Peaches on the open walls here are half a crop, and the same may be said of Apples and Pears; Plums are a good crop; Gooseberries, Currants, and Raspberries, first rate.—RODERICK McDONALD.

—Scone Palace.—In the gardens here, Apples are a failure; Pears, partial; Plums, variable—some trees none, others require thinning; Morello Cherries and Apricots, a full crop; Gooseberries, Red and White Currants, below average; Black kinds, nearly a failure; Filberts, a full crop on some trees, on others few. In this neighbourhood the general outdoor crop of fruits is partial; Gooseberries, in some localities, very scarce, in others, here and there, a full crop; and the same may be said of Currants; Apples and Pears, partial, here and there good, in other places scarce; Apricots and outdoor Peaches, good; Strawberries, which are here a field crop, are reported to yield at the rate of a pound to the yard, a money value of from £60 to £121 an acre. Some cultivators only take two good crops from them, then trench 3 feet deep, and re-plant the same crop again and again, harvesting, on an average, from 2 to 3 tons an acre.—JOHN HALLIDAY.

—Dupplin Castle.—The bloom on fruit-trees of all kinds was very abundant; but late spring frosts not only destroyed much of it, but also the fruit that was set. Apricots are a splendid crop here, although many in the neighbourhood have been damaged by frosts. Plums are a very scarce crop, Denyer's Victoria being the only variety that is bearing what may be called a crop. Apples are also very scarce here; but, in some places, these are good crops. Pears, too, are not half a crop. Strawberries are abundant, and extra good in quality. Cherries, with the exception of Morellos, which are excellent, are very thin. Filberts are an average crop. Small fruits of all kinds very plentiful here; but, in some other places, very few. Peaches, in the open air, none; in houses not heated, a good crop.—JOHN BROWNING.

—Taymouth Castle.—Small fruits, Plums, and Cherries are abundant hereabouts; but Apples and Pears are below the average.—ROBERT MONTGOMERY.

East Lothian.—Whittingham, Prestonkirk.—Apricots, extra large crop and looking well; Apples, average crop; Cherries, very large crop and well flavoured; Currants, of all kinds large crop and good in quality; Pears, a moderate crop; Peaches, none grown out of doors here, but where they are grown they are an average crop; Plums, of all kinds are an extra large crop, except Green Gage, and even of that there is a fair crop; Gooseberries, a large crop and well flavoured; Raspberries, average crop; Strawberries,

plentiful, but owing to want of rain when the fruits were swelling, they are not so large as they might have been, but their flavour is good.—JOHN GARRETT.

Yorkshire.—Culzean.—The fruit crop here this season is pretty good, especially Currants, Gooseberries, Raspberries, and Apples. Strawberries have been poor here; but, in some gardens in this district, they have proved a good crop. Wall fruit, especially Pears, is very scarce; dessert Plums, except Victoria, not more than half a crop; Cherries and Apricots an ordinary crop; standard fruit is more abundant, especially Apples and Pears. All small fruits have suffered very much this season from blackbirds and thrushes.—DAVID MURRAY.

SUPPLEMENTARY ENGLISH REPORTS.

Sussex.—Petworth.—Apples are abundant hereabouts on high ground, but scarce on low lying districts; Pears are very plentiful; and of Plums there are wonderful crops; as regards Damsons, every old stump of a tree has some fruit on it. I have had to thin most of my wall trees and all my pyramids. Both Plum and Cherry trees are much blighted, although on the latter there are heavy crops. Strawberries are plentiful and the fruit fine; Raspberries, good; Gooseberries and Currants of all kinds abundant, but the fruit is smaller than usual; Apricots are plentiful, especially on some old trees that were removed last autumn; Peaches and Nectarines, good; Filberts and Cob Nuts, fair crops; Walnuts, plentiful; Figs, a fair crop; Mulberries, plentiful; Cranberries, Quinces, and Medlars, good crops; outdoor Grapes are plentiful, and the Vines in most places are looking strong and vigorous. I never saw so many aphides, both black and green, as this season; almost all trees are affected by them more or less.—GEO. BRESE.

Hereford.—Shobden Court, Leominster.—Apples are scarce with us here, except in a few favoured places; Pears are fair crops; Nuts, very few; Apricots, in general, fair crops, though, in some instances, the earlier varieties suffered from frost on the 9th of March, when the trees were in full bloom; Plums are good; Cherries have borne fair crops, but, in some cases, they have been so much blighted as to make them useless; Figs are thin and have dropped considerably; Strawberries have been abundant, and good in flavour, but the late kinds have suffered from the continued drought. We have had very little rain here since March; on the 23rd of May we had a few hours' nice rain, but only a small shower or so since. Raspberries, Currants, and Gooseberries have borne large crops. This season we have been fully three weeks earlier than usual, owing, doubtless, to the unusually warm weather which we had in April. Strawberries are nearly over, except a few Elton Pines, as are also bush fruits, except such as are netted for dessert.—J. MATTHEWS.

Surrey.—Deepdene, Dorking.—Apples here are a failure; Apricots are a fair crop; Peaches and Nectarines, moderate; Pears, plentiful; small fruits—Gooseberries, Currants, and Raspberries, fine crops; Strawberries, scarcely an average crop; Figs, moderate; Nuts, scarce.—J. BURNETT.

Portnall Park, Staines.—All fruit crops in this neighbourhood suffered considerably from frost, and the gardens here, being very low, suffered severely from the same cause. Fruits on walls are but thinly distributed, with the exception of Cherries, of which we have an excellent crop, but rather small in size; on espaliers we had a splendid "set," but scarcely a fruit is now to be seen, all having suffered so severely from frost; crops of Gooseberries and Currants are very thin; Strawberries and Raspberries have been abundant and good, both in size and quality; on standards, with few exceptions, the crop has failed.—THOS. MAY.

Worcestershire.—Madresfield Court, Great Malvern.—Owing to the sharp frosts which occurred on May 9 and following nights, hardy fruits, at that time most promising, suffered severely; and, in many cases in low or damp situations, in addition to the loss of the crop, the young growth was cut back. Blight and disease have, consequently, been prevalent among the stone fruits generally, many of the Plum orchards being very short, both in point of fruit and foliage. Wall fruits are better, the fine summer-like weather which we had in the latter part of April having caused the foliage to expand sufficiently to materially shelter both the flower and young fruit. Apricots are, perhaps, more abundant than any other fruit, and are now ripening fast; but, in consequence of the extreme drought, they will not be so large as in more genial seasons. Apples, though partial, are good in sheltered situations; Apricots, a good crop, bright and clean; Cherries, on standards, thin; Morellos, very good; Figs, light, injured by frost; Nectarines, good, and trees clean; Peaches, a good crop; Pears, on standards, partial, on walls a heavy crop; Plums, very few on standards, on

walls a heavy crop; Strawberries, early kinds injured by frost, late crops good; Gooseberries, good; Currants, clean, but crop short; Walnuts, entirely destroyed by frost; Coppice Nuts, a light crop; Filberts, none.—W. COX.

Middlesex.—Syon House, Brentford.—Fruit crops here are, on the whole, barely an average; except, perhaps, Cherries, which have been abundant. Of Apricots we have a fair crop; and the same may be said of Peaches, Nectarines, Pears, and Plums. We have a good quantity of Apples, both on standards and on dwarfs. Strawberries have been plentiful; but rather small, owing to the first fruit having been cut off by frost, and the occurrence of dry weather when they were swelling. Of Raspberries we have had but half a crop, and about the same of Gooseberries and Red and Black Currants. Walnuts here are an average crop; but, in some places in this neighbourhood, they were much injured by spring frosts.—JOHN WOODBRIDGE.

THE WILD PLUMS OF KANSAS.

[Some time ago, it was stated that a traveller in Central America, while passing over the sandy plains of Kansas, met with dense thickets of small Plum trees, not larger than our Gooseberry bushes, bearing fruit of immense size and fine flavour. Several inquiries for further information respecting these Plums not having met with any response, our occasional contributor, Mr. Jackson Gillbanks, who takes so active a part in all branches of natural history, wrote to America to ascertain whether or not such Plums existed, as small bushes bearing large and delicious fruit would be a grand acquisition to both our gardens and orchard houses. This has produced the following interesting letter on the subject from Mr. Ed. Thompson, of Kansas.]

"Lawrence, Kansas, U.S.A., July 3, 1874.

"Dear Sir,—Your letter, relating to the wild Plums of the plains of Kansas, has again directed my attention to them. The head waters of the Kansas River and many streams emptying into the Platte, abound in wild Plums of many varieties and colours; where the soil is fertile and water plentiful, the trees grow to the height of from 6 to 10 feet, and the fruit of many kinds is large and pleasant to the taste. There is one variety of white Plum quite as large and of as good flavour as Bolman's Washington, a kind generally cultivated and much valued in the Eastern States. Another kind resembles the St. Catherine in size and colour. Among the sand hills of the Arkansas, the trees do not reach the size that they do further north, being, in fact, mere bushes 3 and 4 feet high, growing in dense clumps or thickets. The fruit, however, appears to be equally large and luscious, and during the early fall my men have frequently brought baskets into camp, which were exceedingly palatable, either raw or cooked. In the fall of 1872, after we had experienced severe frosts upon the head waters of the Republican, on our way into settlements, upon the north ford of the Solomon, we found a deep arroyo, with a spring, whose sides were filled with Plum trees in full bearing, their sheltered position having apparently delayed the fruitage and protected them from frost. I shall be this year south of the Arkansas river, in the extreme south-western part of this State, and if the Indian's untutored mind does not suggest his raising my hair, I will make further observations upon this subject, the result of which I shall be happy to communicate. (Signed) "EDWARD D. THOMPSON."

POMOLOGICAL INSTITUTE, AT REUTLINGEN, NEAR STUTTGART, WURTEMBERG.

THIS establishment, under the able superintendence of Dr. Edward Lucas, undoubtedly takes a prominent position among horticultural schools on the Continent. Having been a year at the Institute, I will try to give some account of it. It was founded by Dr. Lucas in 1860, and now extends over 21 acres of land. Since its commencement, 696 pupils from various countries have been received. During the winter of 1872 and summer of 1873, there were 71 scholars from the following states:—Baden, 3; Bavaria, 11; Palatinate, 6; Hesse, 1; Pomerania, 2; Brandenburg, 6; Silesia, 3; Province of Saxony, 3; Westphalia, 1; Rhine Province, 1; Hanover, 1; Holstein, 1; Hesse, Nassau, 3; Reims, 2; Saxony, 4; Wurtemberg, 7; Moravia, 2; Tyrol, 1; Transylvania, 1; Switzerland, 6; Denmark, 1; Sweden, 2; America, 2; Africa, 1. As indicated by the title of the institution, pomology is one of its leading features, but instruction in every branch of horticulture is given—Vine-culture, drawing, physics, and chemistry, being taught by competent professors. In the arrangement of the garden, a main walk, 110 yards in length, is planted on each side with a great variety of fruit trees in the form of cordons, palmets, &c., and on the right and left of this walk are the model gardens, where the best sorts of fruits are to be found in the shape of

great pyramids. Farther on is the nursery, properly so called, where, every year, large numbers of fruit trees are trained. Not only is the theoretical instruction at Reutlingen excellent, but, also as regards the practical part, it would be difficult to find a better establishment. From the large number of fruit trees grown, everyone has the best opportunity of practically perfecting himself in fruit-culture. There is also a good geological collection, tools of different countries, an excellent library, artificial fruits, &c. The flora of Reutlingen and environs is a rich one, as the town is situated among high mountains. The botanical excursions which are often made, either with Dr. Lucas or his foreman, are exceedingly interesting, and an excellent herbarium can be formed by those who are desirous of doing so. Not only for its horticultural instruction is Reutlingen recommended, but, owing to the great number of scholars from different countries, the best opportunities are afforded for learning other languages. It is a pity such institutions are so rare!

A. M. C. JONGKIND CONINCK.

Tottenham Nurseries, Dedensvaart, near Zwolle, Netherlands.

THE LARGE VINE AT THE VICEREGAL LODGE.

It is now some years since we first noticed and detailed the history of what is now widely and familiarly known as "The Large Vine at the Viceroyal Lodge." The life story of this very remarkable Vine was then a short one; for, be it remembered, that though a wonderful Vine, it is very far from being an old one. In fact, a decade had not then nearly passed from the time Mr. Smith took it—a poor sapling, struggling for life—in hand. Even then it was a horticultural wonder, filling a curvilinear lean-to house, some 70 feet in length and 15 feet wide, and carrying a magnificent crop of Grapes, quite a picture to look at. Since that time the house has been made a half-span, and has had its breadth thereby considerably increased. Large increase of space was thus afforded for further extension, and so skilfully was the Vine induced to avail itself of it that it soon entirely occupied it; and the long lines of luscious clusters hung as thickly there as in the older portion of the house. It may be as well to mention here, for the information of those who have not seen this Vine, or remember the particulars previously given, that the stem enters at one end of the house, and from this seven main rods are conducted horizontally and equi-distant from one another, in perfectly straight lines, till further progress is arrested where they reach the opposite end of the house. The wood of these main rods is about the thickness of a ship's cable, and the spurs on either side disposed with the utmost regularity, each rod forming a perfectly straight and strongly-defined line fringed with a double row of beautiful stout green foliage from among which depend on either side, as if strung with almost mathematical accuracy, the long lines of sable pendants which are the crowning glory of the Vine. It is now just about eighteen years since Mr. Smith undertook the management of what was then a weakly plant, and is now a giant in its way; and we are inclined to think it, taking all in all, one of the finest examples of successful Vine culture, and perhaps the very best example of what is called the extension system to be met with anywhere. Year after year, without a single blank, it has borne splendid crops of highly finished fruit, and the present year's crop forms no exception, save in one respect, and that is—that as regards size of bunch, berry, and aggregate weight, it will be the finest which this noble Black Hamburgh has yet ripened. The bunches number probably 400 or thereabouts; many of them, we calculate, will weigh 3 pounds or so, and the average is 2 pounds or over; the aggregate weight of crop, we suspect, little short of 7 cwt. The bunches are just now colouring, and by-and-bye, when they put on their full sable habiliments and rich bloom, the big Vine will be a sight worth looking at—a triumph of cultural skill, upon seeing which he would be cold and phlegmatic, indeed, who would withhold from Mr. Smith his warm appreciation of his skill, and the remarkable results of it before him.—*Irish Farmers' Gazette.*

A large Crab Tree.—When lately visiting (said Sir R. Christison, at a late meeting of the Edinburgh Botanical Society) a friend at Kelloe House, in the parish of Endrum, a few miles eastward from Dunse, I was shown a Crab tree, which appears to me to deserve being added to Mr. McNab's memoranda of large trees in Scotland. Crab Apple trees are more frequently met with in hedge-rows in Berwickshire than anywhere else in Scotland where I have been; possibly, because nowhere else in Scotland do hedge-rows abound as fences. The tree in question, according to the information supplied by an old man upon the estate, stood with several others in a hedge-row, but the hedge-row was cut down to improve the highway. This particular tree was, however, so large, even at that time, very many years ago, that it was left standing in a convenient triangular space, in front of

Kelloe Gate, where it does not interfere with the roadway. It has now a trunk of 8 feet in girth, is 50 feet in height, branches freely, and was covered with leaves when I saw it. The fruit was clustered, as in the Cherry. In the spring the whole tree was one sheet of white flowers; but little fruit formed on it, in consequence of the sharp frosts in May. It is well known in the surrounding country, whose inhabitants visit it from a considerable distance when it is in flower. It continues to be perfectly healthy in every part.

GARDENING FOR THE WEEK, AND AMATEUR'S CALENDAR.

The Flower Garden and Pleasure Grounds.

THE time has now arrived when it is generally considered advisable to commence the propagation of the various species of plants used for the purpose of bedding out in the flower garden, &c.; but in this part of the country, and no doubt in many other parts, there will this season be found a difficulty in obtaining material wherewith to form cuttings, more particularly as regards the different kinds of Pelargonium, which, generally, play so conspicuous a part in the ornamentation of the parterre, and it may, in some instances, be necessary to delay for a time the propagation of this family of plants. But there are several other varieties of bedding plants, of each of which it is only necessary to have a few store pots to preserve during winter, in order to produce cuttings for the purpose of increase during spring, such as the Verbena, Petunia, Fuchsia, Lobelia, Coleus, Iresine, Heliotrope, Ageratum, Alternanthera, &c.; therefore, if cuttings of these can be obtained now they should be inserted without delay in pots some 6 or 8 inches in diameter, which should be well drained, using a soil composed of about equal parts of river or silver sand and finely-sifted leaf soil, putting in each pot an inch or two of somewhat rough soil upon the Moss which covers the drainage. The pots should then be filled with the prepared soil, and the cuttings inserted, watered, and placed upon cinder ashes in a frame or pit, which should be kept quite close and moist for a few days, and shaded from bright sunshine. When the cuttings are fairly rooted, they should be at once exposed to the open air night and day, when they will become well-hardened and robust; and may so remain until there is danger from frost, when they should be placed in a greenhouse or pit during winter, and if introduced into genial warmth in spring, say early during the month of March, they will then produce abundance of cuttings which will root freely, and are much to be preferred to autumn-struck plants for planting in the flower beds. It may, however, be necessary to observe, that such plants as the Alternanthera, Iresine, Coleus, Heliotrope, and the dwarf variety of the Ageratum, being somewhat tender, will require to be wintered in a stove temperature. It is also quite unnecessary to pot off singly any of the varieties of bedding-plants which have just been named, as all of them will succeed equally well, if not better, if they are merely shaken from the store or cutting pots and planted at once in the flower-beds. The case, however, is somewhat different as regards the various sorts of bedding Pelargoniums, as they should all, if possible be struck early in the autumn, placing four cuttings in a 4-inch pot, and these should be potted off singly in spring. This should, if possible, be done with all the zonal varieties, and it is more particularly necessary to do so with the variegated zonal or tricolor sorts, which should, if possible, be strong well-established plants when turned out, as their development in the flower beds is not so rapid as that of the green-leaved zonals, and the various Ivy-leaved sorts, which will generally succeed well if struck as cuttings in 4 or 5-inch pots, and separated when planted in the flower-beds. The various varieties of this section of the Pelargonium family, form excellent bedding plants, and do not, as yet, appear to be appreciated according to their worth or adaptability for this purpose. They, however, form exceedingly effective bedding plants, and are very suitable where the soil is light and dry, and will be found to succeed well during seasons and in situations in which the Petunia and Verbena, &c., would entirely fail. Among the best bedding varieties in this section of plants, are the old Crimson Ivy-leaved, the pink-flowering variegated variety, Duke of Edinburgh, Bridal Wreath, the last-named forming one of the most beautiful and effective white beds which can be imagined, together with some other varieties which are hybrids between P. lateripes and zonal species, such as Willsii, Willsii roseum, Lady Edith, and Dolly Varden; the last is a variety with beautifully zoned bronzy foliage and pretty pink-magenta coloured flowers. Cuttings should also be struck, as soon as they can be obtained, of the more free-growing sorts, such as Peltatum elegans and L'Elegante, which are useful for training upon the handles of rustic baskets or drooping from the sides of vases, &c. Continue to regulate the develop-

ment of climbing plants of all sorts, such as Roses, Honeysuckles, Clematises, Tropæolums, and similar plants, which are so useful and ornamental when trained in the form of standards and pyramids, &c. On account of the drought which has so long prevailed, comparatively little mowing has been of late required, but lawns should, nevertheless, have constant attention in that way, as well as in extracting weeds and sweeping off the decayed leaves which are already falling rapidly from the trees and evergreen shrubs; this is, of course, to be ascribed more to the prevailing dry weather than to the—as yet—but slightly advanced season. Let all recently-transplanted trees and shrubs have every necessary attention, and carefully avoid allowing them to become too dry; as this, if allowed, will be sure to have an injurious effect upon recent root formation and will considerably retard the recovery or re-establishment of the plants. The mulching around the stems of such trees should also be covered with large stones or flints, in order to improve its appearance, and prevent birds from disturbing it.—P. GRIEVE, *Culford, Burg St. Edmunds.*

Roses.

All who wish to keep up a continual supply of cut Roses throughout the autumn, should lose no time in removing all old flower-stakes, which should be cut back to the first leaf bud. Thin out all weak shoots, and keep the trees clear of mildew by means of occasional dustings of sulphur whenever it shows itself. Give plenty of water, in order to encourage second growth. Remove all suckers, and tie up all shoots of strong-growing varieties, in order that heavy rains in autumn, should we get any, may not break them down. When Roses are properly attended to, as to removing all faded flowers, a good supply of fresh blooms may be obtained out-of-doors from June until November. On no account cut away strong growths of climbing kinds or of Tea Roses, as on that growth much depends as regards a good supply of bloom the following season. Those who have only a limited space for Roses, and who wish to make the most of their autumn flowers when cut, may effect this as follows:—Get some small phials, place the stalks of a single Rose and one leaf in the bottle, and plug them in with a small piece of sponge. By selecting one bloom only, and placing it in a phial, as just directed, the side buds are saved for succession, and double the quantity of bloom is left for furnishing that otherwise would be available for that purpose. Such small bottles (1½ inch long) may be used in almost any kind of flower stand, and Roses last well cut and put into water in this way.—H. G.

Hardy Flowers.

During the last few years a race of very charming bedding Violas has been introduced, remarkable for varieties having pretty tints of blue and violet, some flowering early enough for the spring display, others being later, and coming in with the summer bedding plants. The immediate progenitor of this race was *Viola cornuta* Perfection, so named because reputed to have been a seedling from the well-known *Viola cornuta*. This *Viola* Perfection has pale violet-blue flowers borne on stiff erect stalks; the habit of growth is dwarf and free-branching; but, as it does not flower till May, it is only adapted for summer beds. It supplies a tint of blue of great value in the flower garden—better than any other bedding plant can furnish it. One of the most useful of the varieties that have sprung from this is *Viola* Bluebell. This is a very early and free-flowering form, producing a large number of violet-blue flowers, commencing in the month of March and continuing onwards till November. This is equally well adapted for spring as for summer bedding, and, in fact, comes into bloom as early, if not earlier, than any other bedding Pansy or *Viola* in cultivation. It is comparatively new, and, therefore, not in general cultivation; when it becomes better known it will be as commonly employed in the decoration of our gardens as the blue *Lobelia*. *Violas* *Euchantress*, *Magnificent*, and *Sensation*, are all derived from Perfection, but, like their progenitor, bloom only during the summer, not the spring months. These are also darker than the parent, and are very useful for massing, for ribbon lines, and also for mingling with silvery-leaved foliaged plants. This is a charming combination, as, for instance, a bed of the old *Mangles* variegated *Geranium*, or one of the new variegated Ivy-leaved varieties, mingled with a blue *Viola*; for here there is foliage and flowers in pleasant contrast. Another charming *Viola* is *Princess Teck*. This has pale greyish-lilac flowers, which are produced in abundance, and it affords a colour perhaps only obtained in the *Verbena*, and then only imperfectly so. Those who plant their beds in the autumn or early winter, to have a spring display, should use for the purpose the divided plants that have flowered the previous summer, as the old wood will flower earlier than the young growth, and plenty of young wood will be furnished to keep up a succession of bloom. For summer work, cuttings struck during early spring should be used, as they make fine young flowering plants during the summer, and also do well when divided for the spring garden. All *Violas* throw up a

large number of young shoots from the roots, and are thus constantly forming a dense growth; and they should be encouraged to do this as much as possible for the sake of a succession of bloom.—*Quo.*

Indoor Plant Department.

Fuchsias and Lilies now constitute the principal flowering plants in conservatories and greenhouses. Gladioli in pots are also very ornamental indoors, as are also different kinds of Bell-flowers. *Humea elegans* is likewise a useful plant in conservatories. Annuals, such as *Schizanthus*, *Zinnias*, *Celosias*, *Balsams*, *Gomphrena globosa*, and several kinds of *Amarantus*, also contribute considerably to the decoration of cool houses. Where *Amarantuses* are wanted for succession they should be kept in frames, and re-potted as they require that attention, taking care, however, not to over-pot them. *Trachelium ceruleum* is one of the most useful of flowering plants. In order to keep up a succession of Balsams a reserve stock of them should be kept in cool pits or frames; from these the blooms should be picked off as they appear, until within a week or two of their being wanted for use. Hard-wooded plants put outside to ripen their wood and to make room for gayer subjects indoors, should receive any little attention they require in the way of supplying them with water. Show and fancy *Pelargoniums* cut over, some of them pretty well into the old wood, and such as are the most shapely, to a joint beyond that to which they were cut back last year, should be placed on a shelf and kept dry, or laid on their sides out-of-doors. In stoves wood-ripening must be encouraged; no more shading should, therefore, be used than is absolutely necessary. Among the gayest plants at present in stoves are *Allamandas*, which, in all cases, blossom best when their roots are allowed to ramble in some bed or border of good soil, and when their shoots are trained along the roof. Thus circumstanced they give more satisfaction than when tied around pot trellises. Of *Achimenes*, *Gloxinias*, and other *Gesneraceous* plants, several are still in bloom, but such as have done flowering should be laid on their sides to prevent their roots becoming injured by drip; such *Gesneras* as *exoniensis*, *zebrina*, and others of that section, should be encouraged to come in succession, being admirable plants for indoor decoration. In re-potting these the soil should not be shaken from the roots, only the crocks should be removed. As some of the earlier-started *Caladiums* show symptoms of decay they should be removed to some out-of-the-way place and gradually dried off. Some venture to keep them in a green or growing state throughout the winter, but that is not good practice, though occasionally it may succeed. Plants of *Clerodendron* *Kaempferi* that have done blooming should be set aside and gradually dried off, whilst those coming into bloom should be supplied occasionally with manure-water. This *Clerodendron* strikes freely from cuttings of mature wood inserted in spring in a brisk heat. Those put in last spring should now be strong enough to be re-potted in 6-inch pots, and may be kept in a stove temperature. Rotten manure, yellow turfy loam, a little peat, and a good admixture of sharp sand suit them admirably. Pits and frames will now be becoming filled with cuttings of *Heliotropes*, *Verbenas*, and some of the finer kinds of *Geraniums*. For *Ageratum*, *Gazanias*, and *Calceolarias*, there is yet time enough; indeed, they are seldom put in until the others are rooted, lifted, and potted, or put thickly into boxes. *Chrysanthemums* should, for the most part, be placed in sheltered positions on a bed of ashes, out of doors; still, however, a few should be kept in frames, especially young plants, to which plenty of air should be given. Many of the most forward *Cinerarias* will now need a shift from small pots into 4 or 6-inch ones, using a good deal of well-seasoned rotten manure in the compost. Seedlings should be re-potted as they require it. A sowing of herbaceous *Calceolarias* may now be made; some prefer to sow late and to encourage the seedlings for a while with heat, while others sow earlier and treat them more hardily. *Anrinculas* should be re-potted and placed in frames that face the north. *Cyclamens* should also be re-potted and placed near the glass in frames or pits, and syringed every day. A gradual increase of moisture may be given at the root. Pansies should be propagated by means of cuttings inserted in sandy soil in frames, and well shaded for a time.

Orchids.

Dendrobiums, *Cattleyas*, *Lalias*, *Oncidiums*, and other plants which have completed their season's growth, will now be benefited by being removed to a dry airy atmosphere, and may be more fully exposed to the sun, so as to thoroughly ripen their pseudo-bulbs. This treatment does much towards inducing a free flowering disposition the following year. It is a good plan to utilise sunny Vineries for ripening off the growth of *Dendrobiums* and other Orchids on blocks or baskets. Thorough ventilation is one of the most important aids to good cultivation at this season, and in fine weather the ventilators may be opened early in the morning and closed as soon after mid-day as the temperature will admit. The cool houses should

have a free circulation of air night and day, and at this season, when nearly all the species are making a vigorous growth, it is nearly impossible to keep the atmosphere too moist and cool. Potting may still be proceeded with in the case of strong-growing plants, and copious supplies of water will be needed where plants are making a vigorous growth. Phalenopsis may be gently dewed with a fine syringe daily, early enough to allow the foliage to become dry before the evening. Keep all pots, pans, benches, and floors scrupulously clean, and repeated spongings with clean tepid water will also greatly assist in giving a healthy appearance to the plants. It often happens that where much aerial moisture is maintained, some plants of succulent habit show a tendency to spot. This is especially the case with Phalenopsis, and, as soon as this is discovered, the part infected should be removed with a sharp knife, and the wounded part dusted with a mixture of sulphur and powdered charcoal, to which a little quick-lime may be added. A pinch of the latter alone is one of the best application in the case of putrid spot, as it seldom fails to burn out the fungoid disease and stay its ravages.—F. W. BURBIDGE.

Indoor Fruit Department.

Pine Apples, just shifted, should be plunged in a bottom-heat of about 85°, and no water should be given them until they begin to form fresh roots. Plants setting, or such as have just set their fruit, should have some good fibrous loam placed around the necks of the stems so as to encourage the emission of new roots. Muscat Grapes require a brisk temperature to ripen them well, and afterwards a proper means should be taken to thoroughly ripen the wood. Second crops of Figs promise to be good; abundance of water should be given them, and syringing should be still continued. To Melons, a high temperature should be maintained and a little air kept on night and day; those ripening require the border and atmosphere to be kept rather dry. Cucumber frames should have their linings renewed. Where crops of Peaches and Nectarines have been gathered, such trees as are in pots should be set outside on a well-sheltered border. Some, however, do not turn out their pot-trees, but keep them always indoors, giving them as much air as they possibly can. Tomatoes in pots should be kept as near the light as possible, and should be supplied occasionally with weak manure water. Chillies in fruit-houses and frames should also be kept near the glass. To these, green-fly is a great enemy; they therefore now and then need a dip into a mixture of diluted tobacco-water in which a little soft-soap has been dissolved.

Hardy Fruit.

Figs in the open air should not have their side shoots stopped. The most profitable mode of culture is to allow a free growth. Back the trees up against a house or wall; tie in the leading shoots until the space is covered, and allow the side shoots to grow freely, so as to form half standards. By this method a great many shoots of medium strength will be produced, well adapted for fruit bearing. The best mode of preventing excess of growth is a poor border, or no border, and a good crop. Out of doors, I prefer no border for the roots of Fig trees. Plant them on a gravel walk, under a paved yard, in the poorest, commonest soil in the garden, and leave the tops almost to Nature, and you are sure of a crop. Prepare a rich border; apply the knife vigorously to the top; thin and display the shoots in an artistic manner, and you will reap wood fit for faggots, and leaves fit for sun-shades, but little or no fruit. Reverse all this as above directed, and the growth will be weakly, the leaves of small size, and the fruit plentiful. Neither do I approve of protecting the tops of Fig trees in winter. On an average of seasons fruit will be much more abundant on the trees left to shift for themselves. Protection weakens the hold of the fruit on the trees so much, that, when it is removed, the fruit is apt to drop, and even the tender leaves and shoots to suffer. But the non-stopping of the shoots, and their non-protection in winter, are, to some extent, linked together; for, by not stopping the wood, the embryo fruit left at the base will continue so small that it resists the winter frosts; whereas, were the shoots stopped, the second crop of Figs would be developed so far that the winter or spring frosts would kill them. It is obvious that only one crop of ripe Figs can be gathered in a season from open air trees; and that crop is the Figlets that cling to the branches throughout the winter and spring, and grow into size and lusciousness, through June, July, August, and September. While the crop of one year is growing that of the next is being formed at the axils of the leaves and the growing shoots in front of them, and in order to keep these small enough to pass safely through the winter, the shoot itself must not be stopped. If there is any deficiency of fruit-bearing wood, that may easily be increased by beheading the side-shoots as they start into growth next year. The stopping will then make little difference to the earliness of the fruit, while it will furnish several fruit-bearing shoots set with Figlets for

another year instead of one only. All weak shoots that have little or no fruit on them may now, also, be cut back, quite home to the main branches; this will ensure a supply of fruit-bearing shoots nearer to the main limbs of the tree than they otherwise would be, and provide a supply of wood against a necessity that may sometimes arise under this system of free and easy Fig culture, viz., that of cutting back to get nearer to the wall—the source of protection and cause of superior warmth; for, of course, it would be possible to travel so far from the wall by this mode of culture as to make the trees share the climate of standards, instead of half standards only as intended. The same mode of training, and little or no pruning, answers well for the growth of Figs on roofs. For the latter, separate trees should be planted, and for this reason, that, if the head of a tree covering a wall is once allowed to run at will over a roof, the chances are that it will become headstrong. The top will run away with the strength and fertility of all the other parts of the tree. The roof becomes productive at the expense of the walls. To avoid this, plant rider Figs, that is, those with a long clean stem to reach up to the roof, and then let them break, and train and cover as you would a wall. There is no other safe mode of covering a roof with Fig trees, for, if trained thinly over tiles or slates, the fruit will be burned before it is ripe. The long clear stem is also an aid to fertility, whether from the distance between root and top and the length of sap vessels traversed by the sap, or from some other cause, it is not easy to say.—D. T. FISH.

Kitchen Garden.

Now that rain has fallen copiously, finish planting late Broccoli and all kinds of Winter Greens. Walcheren and Veitch's Autumn Giant Cauliflowers, should also be planted for late autumn use on well-manured land, in an open position. Sow a good breadth of Prickly Spinach for standing the winter; also, the Giant Rocca and White Tripoli Onions. Parsley may yet be sown for late spring picking; it will not run to seed quite so soon as that sown earlier. Make a good sowing of Endive, of both the green curled and Batavian varieties for winter. The earliest sown crop will now be full grown, and portions of it should be tied up and blanched in succession; the blanching may easily be effected at this season by covering each plant with an inverted flower pot, with a bit of Moss twisted into the hole to keep out wet, air, and light. Plants from the successional sowings, now that rain has come, should be planted out on well-prepared land, 1 foot apart, at intervals of two or three weeks. This is a good time to sow a good breadth of Red Stone and Orange Jelly Turnips for winter use; they may be sown on land from which early Potatoes have been lifted, without any further preparation of the soil, beyond levelling, raking, and working up a fine tilth. It will be best to sow in drills; and it will be a great advantage to the crop if about three or four pounds per rod of super-phosphate, mixed with about twice its bulk of wood ashes or burnt earth, are sown in the drills with the seeds. The season has hitherto been too dry for artificial manures to have much effect; but we shall now probably have a period of cooler, moister weather. Chervil is always in request; therefore, make a sowing for winter; and, when the plants are large enough to prick out, fill a box or two with the thinnings to place in a frame for use in bad weather. Provision should also be made to have a supply of Sweet Marjoram in a green state through the winter. This is best done by filling a box or two with the young plants in May, and keeping them pinched back; but plants may be lifted now from the border, shortened back, and planted in boxes. It bears forcing well for the production of young green shoots in winter; and, as it strikes freely from cuttings in heat, if desired, a stock of young plants may be worked up in spring for planting out. Early Horn Carrots may yet be sown to supply small young roots in autumn and winter. Tomatoes will now require a good deal of attention as regards the removal of all superfluous growth from the main stems, and stopping all leading shoots one leaf beyond the clusters of fruit. This must be carried out persistently, if good-sized well-ripened fruit is desired. The blanching of early Celery usually requires about four or five weeks; and, as there is not much chance of watering it effectually after earthing up has commenced, it is better to delay this process till the Celery is nearly fully grown, or till within a month or so of its being required for use—then earth it up the full height at one operation. Ridge Cucumbers will now require a good deal of attention as regards the proper regulation of their growth and pinching out the points of the longest shoots; in all cases mulching should have been resorted to during the late dry weather. The season during which Cucumbers can be successfully grown in the open air in this country is usually a short one; therefore, every expedient that has a tendency to make the growth healthy, regular, and continuous, should be adopted. Box edgings may still be cut, and advantage should be taken of this change in the weather to have all gravel paths firmly rolled down.—E. HOEDAY.

THE HOUSEHOLD.

A CHAPTER ON TOMATOES.

I SEND you my ways of disposing of the Tomato, which I call the vegetable of vegetables. If any of your housekeepers can add to, or improve this list, I trust they will do so. I am by no means prejudiced in my own mode of doing things; and, if I can aid any one in using the Tomato in many ways to advantage, I shall be content.

Stewed Tomatoes.—I shall say nothing about stewed Tomatoes, as it is presumed everybody knows how to stew them. One thing, however, should be remembered—that nothing should be mixed with the pure article, which should pass through a sieve or colander before being sent to the table, though some mix with it a little chipped Onion well boiled.

Tomatoes au Plat.—Butter a warmed metal or earthenware plate that will stand the fire, add pepper and salt, and cut, in the flat direction, as many Tomatoes as, when placed with the cut sides downward, will cover the plate. Cook before the fire, placing a tin reflector behind. When slightly browned, they are ready. Three or four eggs may be broken into a cap and placed in the Tomatoes three or four minutes before they are removed from the fire.

Tomato Catsup.—Take ripe Tomatoes, and scald them just sufficient to allow you to take off the skin; then let them stand for a day covered with salt; strain them thoroughly to remove the seeds. Then to every two quarts add three ounces of cloves, two of black pepper, two nutmegs, and a very little Cayenne pepper, with a little salt. Boil the liquor for half an hour, and then let it cool and settle. Add a pint of the best cider vinegar, after which bottle it, corking and sealing it tightly. Keep it always in a cool place. *Another Way.*—Take one bushel of Tomatoes, and boil them until they are soft. Squeeze them through a fine wire sieve, and add half a gallon of vinegar, one pint and a half of salt, two ounces of cloves, quarter of a pound of allspice, two ounces of Cayenne pepper, three table-spoonfuls of black pepper, five heads of Garlic, skinned and separated. Mix together, and boil about three hours, or until reduced to about one-half. Then bottle without straining.

Tomato Omelets.—Beat six eggs, mix two tablespoonfuls of flour in a little water, and add same salt and pepper; peel and chop very fine four Tomatoes, stir this altogether. Put a bit of butter half the size of an egg into a frying-pan, heat it hot, turn on the mixture, stirring it all the time until it begins to thicken; then let it stand to brown three minutes, lap it half over, slip it on a dish, and send it to table very hot.

Pickled Tomatoes.—Always use those which are thoroughly ripe. The small round ones are decidedly the best. Do not prick them, as most receipt-books direct. Let them lie in strong brine three or four days, then put them down in your jars, mixing with them small Onions and pieces of Horseradish; then pour on the vinegar (cold), which should be first spiced; as for peppers, let there be a spice-bag to throw into every pot. Cover them carefully, and set them by in the cellar for a full month before using. *Another Way.*—Take small, smooth Tomatoes, not very ripe; scald them until the skin will slip off easily, and sprinkle salt over them. After they have stood twenty-four hours, drain off the juice, and pour on a boiling hot pickle, composed of one pound of sugar to every quart of vinegar, and two teaspoonfuls each of cinnamon and cloves. Drain off the liquid, scald it, and pour it on them again, every two days for a week, and they will require no farther care.

Tomatoes in a New Fashion.—The following method of preparing Tomatoes for the table, we are assured by one who has made the experiment, is superior to anything yet discovered for the preparation of that excellent article: Take good ripe Tomatoes, cut them in slices, and sprinkle over them finely pulverised white sugar, then add claret sufficient to cover them.

How to Make Tomato Figs.—Pour boiling water over the Tomatoes in order to remove the skins; then weigh them and place them in a stone jar, with as much sugar as you have Tomatoes, and let them stand two days, then pour off the syrup, and boil and skim it until no scum rises. Then pour it over the Tomatoes, and let them stand two days, as before, then boil and skim again. After a third time they are fit to dry, if the weather is good; if not, let them stand in the syrup until drying weather. Then place on large earthen plates or dishes, and put them in the sun to dry, which will take about a week, after which pack them down in small wooden boxes, with fine white sugar between each layer. Tomatoes prepared in this manner will keep for years.

Tomato Preserves.—Take the round yellow variety as soon as ripe, scald and peel; then to 7 lbs. of Tomatoes add 7 lbs. of white sugar, and let them stand over night. Take the Tomatoes out of the

sugar and boil the syrup, removing the scum. Put in the Tomatoes and boil gently fifteen or twenty minutes, remove the fruit again and boil until the syrup thickens. On cooling put the fruit into jars and pour the syrup over it, and add a few slices of Lemon to each jar, and you will have something to please the taste of the most fastidious. BETTY.

A Successful Mode of Drying Fruit.—I have several times noticed that successful and deserving process of fruit and vegetable drying—the Alden—now in full operation at San Lorenzo and five or six other places in California. This process is now fast becoming generally known. It removes the water from animal and vegetable substances in a few hours, by pneumatic evaporation. The conditions of the natural or common method of drying are such, that decay commences before evaporation begins, and continues through every stage of the process, until all the essential flavours, which constitute the charm of freshness, are lost. The most delicate fruits and berries, and the ordinary products of the farm and garden, are, when subjected to this plan, in from two to four hours deprived of water, and become also greatly reduced in bulk (for instance, three ounces of Pears dried by this process would, by the ordinary method of preserving, have weighed two pounds—a great item in the expense of transportation), and can, at any time, by simply soaking in cold water, be restored to their original flavour, form, and substance.—W. E. HOOPER.

THE WAIL OF SMELFUNGUS.

It was an old Mycophagist
Who sadly did complain
He had his favourite Toadstools missed
From lengthened want of rain.
His brow, with discontent o'ercast,
A rueful aspect wore;
Said he, "There has no Fungus passed
These lips this month and more!"

"Saint George's Mushroom, one or two,
I found in early Spring;
Agaricus gambosus, due
With swallows on the wing.
Lycoperdon, too, *giganteum*,
Two light repasts supplied;
And then, alas! no more would come
From pastures too soon dried.
"*Marasmius Oreades*,
Which wet in season brings,
The buff Champignon, that one sees
In verdant elin rings,
When seared were all those circles green,
No seeker's eye could see.
What disappointment that has been
To fairies and to me!"

"The *Amanita* changing hue,
Rubescens, blushed me none;
The *Russula heterophylla*, blue,
And puce, I found not one.
And as for the *Boletus edulis*, so plump and fat,
A Fungus which I love to see,
I found no more of that.

"The *Fistulina hepatica*
Grows out of the Oak tree,
Like liver to behold, but, ah,
Has not yet grown for me!
Coprinus, eke, *comatus*, fails;
Atramentarius, too;
For ketchup neither aught avails,
So what am I to do?"

"I can but sigh for heavy rains,
And thunderstorms implore,
With *Agarics* to make all the lanes
And meadows teem, galore.
The farmers might wet weather weep,
But I hot summer mean,
Forbidden by the drought to reap
A harvest of my own."—Punch.

OBITUARY.

WE regret to announce the death of Mr. John McMorran, many years superintendent of Messrs. Backhouses' nurseries, at York, and an accomplished horticulturist, and amiable man both in business and in private life.

THE GARDEN.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

ARCHITECTURE AND FOLIAGE.

What to do with Temple Bar.

It appears that the entrance to Victoria Park from the station on the North London Railway consists only of an insignificant wicket gate; a most suitable site, therefore, presents itself at that point for the re-erection of the old barrier whose history is so intimately bound up with many stirring events connected with the metropolis. The removal of the Marble Arch from the Mall, in St. James's Park, where it was a patchy obstruction, to its present situation, in which it forms a handsome and suitable decoration to one of the principal entrances to Hyde Park, is a wholesome precedent. It illustrates the hint just thrown out, and seems to point to the propriety of a somewhat similar change. In its present state, Temple Bar cannot be allowed to remain where it is. Whether in consequence of the deep foundations dug in its close vicinity in preparation for the new Law Courts, or from the continuous jarring of the continuous traffic, it is unnecessary to inquire, but certain it is, that the structure has, within the last week, shown unmistakable signs of menacing disintegration. To re-erect the materials upon the same spot, upon a new foundation, will certainly never be permitted, after all that has been urged concerning the impediment which it has so long proved to the traffic of the Strand and Fleet Street. Such a course appears entirely out of the question—while, to destroy the old monument, by simply carting away the materials as used-up rubbish, would certainly be an act of vandalism. The first claim to the relic has been urged in favour of Victoria Park; and, therefore, if any competition for the old City gate should arise, the east-end park should, as it seems, have the preference, unless sound reasons can be urged to the contrary. The park in question already possesses architectural relics of a somewhat analogous character in the massive stone alcoves that once formed part of old London Bridge. These structures are of solid and fairly good design, and contrast pleasingly with the foliage with which they are now surrounded. They are, in fact, in their present locality, far more agreeable objects than they were in their bleak and unsupported position on London Bridge; and the old archway that has so long formed the highly inconvenient western entrance to the City, will, in like manner, if removed as proposed, be seen to far greater advantage in the midst of green turf and noble foliage. It has considerable merit in point of design; indeed, in that respect is undoubtedly superior to the wretchedly meagre and slavish copy of Greek art exhibited by the Marble Arch, which owes all its beauty to the material of which it is composed, and all its interest to being the first attempt to erect a structure entirely of marble in our unfavourable climate. This view will be rendered manifest when the old Bar is placed in a better situation; not jammed tightly in by dingy houses, but well supported on either side by the living green and grandly irregular forms of fine trees. From a gardening point of view the particular placing of the structure in Victoria Park becomes a point of considerable interest; the kind of foliage, and its extent, by which it ought to be supported would form a very interesting study to an accomplished landscape gardener, as well as the solution of the question whether its façade should be placed flush with the roadway surrounding the park, or at a certain short distance within the boundary, and approached between plantations of well selected trees, which might be planted so as to expand by degrees, and form masses of supporting foliage on either side. These considerations may be premature, inasmuch as the Corporation of the City of London may, in its wisdom, determine to strengthen, or even re-erect Temple Bar, where it now stands tottering, but suggestions are better made too soon than too late. It is, perhaps, needless to add that many positions in our west end parks would be equally suitable for this structure or any similar one.

THE SHAKESPEAREAN GARDEN.

GARDENERS usually love flowers purely and solely because of their beauty; artists love them (though in their inmost hearts they love trees far better) because they afford subjects in the imitation of which they have scope for their charming powers; the poets, the true and genuine poets, as distinguished from versifiers, rhymesters, and paper-stainers, love them, as the gardeners do, for the sake of their sweet complexion, but, at the same time, because of the pictures they supply to the mind. And this, perhaps, is the noblest purpose for which flowers were created. The gratification of the simple sense of seeing is a very inferior enjoyment compared with the delights of which the intellect is capable; and these last, in many of their richest forms, are derived from plants and flowers. The eye must needs be pleased in the first instance; it is the living instrument by means of which the mind talks with Nature. The error, too common among mankind, is to rest content with what it says as to prettiness of forms and colours, and to inquire no further. It is quite a mistake to suppose that seeing a thing, or even owning a thing, is exhausting it; that we have done, for instance, with the Rose, when we have learned its botanical structure, the conditions of its most excellent blooming, and the chances it may have of winning at some grand competitive flower-show. Such knowledge is very pleasant, very proper, useful, and creditable; but, if we go no further, we are only playing on the outside, and are like little children on the shore, who pick up the shells and erimson weeds left in the brown wrinkles of the sand by the retiring water, uncouscious of what is found by those who sail afar in ships. The poet teaches us how to see beyond the surface. Every man, therefore, who would get the full value out of his trees and flowers, should try to cultivate a poetical spirit. Some few of our fellow-creatures are rich in this respect, just as some are rich in mechanical ingenuity, others in aptitude for mathematics, or for legislation, or some other valuable but not superior art; and these rich ones are the poets, properly and legitimately so called. Whether skilful or not in rhyme and metre does not matter; they are poets in the fact that they see farther than the other people do; they make common things glorious; they show us that the little and the unpretentious is no less worthy than the large and imposing; they let us into the inner life and the sweet and loveable meaning and purpose of trees and flowers.

Shakespeare, with whose plants and flowers I am about to deal, is pre-eminently the poet of Nature; for that matter so is he pre-eminently the poet of the heart, no man ever having sounded the depths of the affections so thoroughly and so accurately as he has done. At present it is enough to consider him in his capacity of lover of the woods and fields; as the man who has made more frequent and more truthful mention of the elements of vegetable nature than any other whose writings the world possesses; and who, in matters of correct teaching, is far before many a learned lecturer or college graduate. That a gardener can do without him, of course, is quite true; so can he do without Linnaeus and De Candolle. That he can dispense with that critical knowledge of his works, which is conventionally called "understanding Shakespeare," I have no objection to concede. This, however, is a very different thing from dispensing with Shakespeare as a tutor, which no intelligent gardener will ever do. In the little articles I propose to write on the flowers and plants of which he makes mention, I shall constantly regard him, accordingly, as the gardeners' friend. If Shakespeare be not the gardeners' friend, depend upon it he is friend to no one else.

On going through his plays, I find that of our English wild flowers Shakespeare mentions about fifteen, alluding to some only once or twice, to others a dozen times. Of exotic flowers, or such as were cultivated in the scanty gardens of his period, more than 300 years ago, he mentions nine or ten. Of trees and shrubs, exotics included, there are notices of about twenty-five. Of fruits, whether ripened in England, or imported from foreign countries, I find the names—sometimes often recurrent—of about thirty. Vegetables are spoken of in about equal proportion. Products of the nature of spices and medicines are mentioned to the extent of about a score; and the same is about the number of what are contemptuously called "weeds." The total is thus

about 150, or very considerably higher—I think considerably more than double that of the total to be found in Milton—and considerably exceeding that of the plants mentioned by the next who is most copious in allusion to plants, the ancient Roman poet in whose *Georgics* and *Æneid* the references are so frequent and diversified. Shakespeare, we must remember, did not set out with a view to talking of trees and plants. His designs were very different, and the allusions are only casual and incidental, a circumstance which renders the total of 150 truly remarkable. In reference to this total we must remember, again, that three centuries ago botany had scarcely found its feet, and that few of our English wild flowers had been discriminated. Shakespeare had no “*floras*” to consult; it is doubtful if he could have found even a botanical teacher. The only books upon plants then in existence were the writings, in Greek, of Theophrastus and Dioscorides, and, in Latin, of Pliny and Columella, with such “*herbals*” and “*histories*” as had been produced in his own age; those, for example, of Fuchs and Wm. Balley. Shakespeare’s library was Nature; his vocabulary was little more than the vernacular; and glorious is the use he has made of these. It seems to me that we ought to be thankful that he lived in an age when science was not yet fledged; when there were neither Eschscholtzias, nor Odontoglossums. Having only simple plants to deal with, he has shown us how all comes right to a master, that the Cowslip is every bit as good an illustration, and comes charged with as much beauty as the proudest *Lælia*, or any other floral aristocrat that fetches ten guineas a root. G.

THE KITCHEN GARDEN.

CELERY CULTURE ROUND LONDON.

THIS is one of the principal crops grown in the valley of the Thames, both on the west and the east side of London, and in other districts where the soil is good, deep, rich, and moist. In market gardens, this vegetable is grown in bulk much better than we generally find it in private gardens. The crop is universally large, crisp, and solid, and neither care nor labour are spared to bring it to perfection; indeed, this is the only outdoor crop in market gardens that is persistently watered. The Red and White Solid are the only two kinds cultivated; they have sometimes the prefix Manchester added to their names, but that signifies nothing, considering that the Celery known as Manchester is only the Red Solid, or a variety of the same that is scarcely distinguishable from the original. The Celery seeds for the first crop are generally sown in February, broadcast, on a slight hotbed, and thinned out a little after they appear. A large or main sowing is made in March, and another for a late crop in April. All these sowings are commonly made in frames in gentle hotbeds, but Mr. Geo. Steel, of Fulham, sows his main crop on an open-air bed as follows:—About the 20th, or some time in the last week of February, he casts out a trench some 15 or 18 inches deep, 6 feet wide, and any length (say 20 yards), and this he fills firmly with fermenting manure, over which a layer of a few inches deep of common soil is placed. All being levelled and well rolled, the seeds are sown broadcast over the whole surface, and slightly covered by sifting some light soil over them. These beds are then covered with rank litter until the seeds germinate, when the litter is removed in favourable weather during the day, but replaced at night until the weather is sufficiently genial for the plants to stand without any covering whatever. The seedlings, either in frames or in beds, are freely exposed, by uncovering, by day and night in favourable weather, and in the case of frames, by tilting up the sashes when the weather does not permit of their removal. When the seedlings in either case become thick, they are thinned a little, but are not pricked out into other frames, except in the case of very early sowings. When they have attained a fair size, however, they are pricked out (in May) in beds in sheltered positions in the open air, in lines 9 inches apart, and 2 or 3 inches asunder in the rows; or they are pricked out in beds 6 feet wide, with

an 18 inch alley between them, nine lines of Celery in each bed. Here they are allowed to remain until time and convenience permit them to be permanently planted out. A great point observed by all growers is to have the ground to be planted cleared of its crop as soon as possible in autumn or early winter, then heavily manured all over, and trenched and ridged, permitting it to remain in this condition until it is required for Radishes or spring Cauliflowers. Generally the Celery is planted in the alleys between the beds of Radishes, thus leaving the rows 5 feet apart, or between alternate lines of Cauliflower in May and June, in which case the Celery will have taken to the soil and begun to grow before the Cauliflowers are all removed. If this sort of interplanting, however, is practised, provision must be made for such at manuring time by marking off the ground in 5-foot breadths, and giving a quadruple quantity of manure under each line, and into this the Celery is eventually planted, thus saving the labour of re-manuring, which would cause a disturbance as regards the spring crop. If the Celery, however, is planted in an open field after the entire removal of a spring crop of vegetables, the ground is cleared of all refuse, dug over, and marked off; and, if it has not been previously prepared by giving the extra quantity of manure in winter, that must now be applied. For the first crop and the main crop the rows are usually 5 feet apart; for the late main crop $4\frac{1}{2}$ feet, and for the latest or winter crop 4 feet apart. No ridges are formed, as is the case in private gardens; but a furrow is merely drawn, with a hoe, as for sowing Beans or Peas, but a little deeper and wider; and into these furrows the plants are inserted by means of a dibber. When a clean field is lined off and ready for planting out with Celery, it is precisely like a field of seed beds, with the beds all 4 feet wide, and the alleys 1 foot wide and about 6 or 4 inches deep. Market gardeners never plant more than one row of Celery in each line, and the plants are about 8 or 9 inches asunder; the strongest are planted out first, and the remainder form successions. Experience has taught growers for market that deep planting is not advisable, more especially in the case of late crops, because when planted deeply the Celery is apt to suffer from damp at the root, and is consequently liable to rot. They therefore plant in such a way that, when finally earthed up, the roots shall be above the level of the trenches. The space between the rows is planted with Lettuces, French Beans, Cauliflowers, Coleworts, or Endive.

Soon after the plants begin to grow strongly, a little earth is drawn to them with a hoe; but earthing-up, properly so called, is generally performed at three different times. In the first operation, which is done when the plants have made large leaves and gained good strength, the soil is placed about the plants from the intervening space, taking care not to rob any of the plants growing on it; and at the next earthing-up the same precaution is observed. By this time, however, most of the catch-crop vegetables will be removed for market. At the two first earthings-up a hollow is left along by the necks of the plants, so as to conveniently retain a good supply of water. At the third and final earthing-up, the ridge is well closed at the top by pressing in the soil against the plants by means of the back of a wooden rake; a man with a rake going on either side of the ridge, and both pressing at the same time, fill up the furrow effectually. Celery ridges are, however, most liberally watered during the growing season, either in the ordinary way, or by means of hydrants, to which 1-inch metal pipes are attached, or common gutta percha hoses where hydrants do not exist; hogsheds placed at intervals in the fields supply water for the purpose. Where watering is not done by cans, the hose is employed; this mode is reckoned to be eventually as cheap as any. One man carries the end of the hose along the ridges, directing the stream of water, whilst another keeps the hose free from twisting; and if the length be great, a third must be employed to help, and to attend to the turning off and on of the water. Towards the end of August the early produce comes into use, and from that time until February a regular supply is kept up. Before lifting the crop, part of the leaves is switched off with a sickle, then, in lifting, a trench is thrown out at the end of a ridge, which is partially levelled, and the crop is removed at the same time; a set of people being employed in lifting,

another in wheeling or carting to the packing shed, and a third in washing, bunching, and packing. Sometimes a very late crop of Celery is grown for use in soups and other dishes. For this purpose the seeds are sown in June, pricked out as usual, and finally transplanted into rows 2 feet apart. As they never grow much, this distance is sufficient for them, for they are seldom earthed up more than once, and if kept until the warm weather sets in, they will certainly "bolt" and become useless. Slugs, especially in moist weather, are sometimes very destructive to Celery leaves; but their progress is arrested by dredging along the tops of the ridges with air-slaked lime, and operating similarly on the banks or hedge-rows surrounding the field where it is grown. Highly cultivated ground, if inland, is seldom infested by this pest; but where there are neighbouring hedges or banks, these slugs are sure to be found, and, no matter how well tilled the soil may be, their ravages will become apparent unless liming is resorted to.—*Child.*

LONDON MARKET PEAS.

THESE are grown in the immediate neighbourhood of London much more plentifully than Broad Beans; nevertheless, ninety-five per cent. of the Peas that comes to Covent Garden Market in summer and autumn are grown in Bedfordshire, distant parts of Surrey, Kent, Essex, Hertfordshire, West Middlesex, Bucks, Berks, and other neighbouring and distant counties. The favourite sorts are difficult to name, on account of the partiality that different growers have for different kinds; certain it is, however, that the early dwarf kinds are universally the most desired, on account of their quick returns, the small space they occupy compared with tall Marrows, and because they require no stakes. Mr. Myatt, of Deptford, prefers Beck's Little Gem to all others for an early crop, on account of its excellence, great bearing property, dwarf habit, and easy management. He sows it in open quarters or fields in rows 2 feet apart, on a dryish soil, in the end of January, and reaps the produce in June. To succeed Little Gem he grows Alpha (Laxton's), which he sows a fortnight later than the other, and in rows 2½ feet apart, and this Pea he considers better in quality than any other sort which he has grown, and the one for which, in preference to all others, his customers inquire. One year he grew all his Peas for seed purposes, because he found it almost impossible to get people to come "Pea-podding;" therefore he had to devote all his labour strength to more pressing work. He did not lose, however, by this, for he realised a very high price for his spare seeds, as when the kinds are good and true, they always demand a ready and high market price. Many hundreds of acres of ground, too, throughout the above-named counties, and on purely agricultural farms, are devoted to the growing of White Peas for seed; and as this crop is got off the ground in good time—about the 1st of August—the ground is at once ploughed over and sown with White Turnips for Covent Garden, where the tops as well as the roots are disposed of. Other sorts that I have found highly esteemed with market gardeners are Early Frame, Croom's Dwarf, and Bishop's Dwarf. As a rule they are sown for a first crop in January, and invariably on a dryish soil, and in as sheltered a place as possible, other sowings being made fortnightly in succession till April, or even till the 1st of July. The demand for Green Peas, however, ceases after the 1st of September; therefore other crops more profitable might be grown on the space they occupy at that time. In many instances the first sowing of Peas is made in December on a warm border; but, considering that they must thus be sown a little deeper than in January, and the risks to which the seeds are liable from mice, birds, insects, and damp, it is a much-disputed point amongst good growers whether the December sowing has any advantage over that made in January; whilst many contend that the produce of the latter is quite as early as that of the former, and the crop is less subject to risks. In making early sowings, it is a practice with market gardeners to choose a fine day to break down the ridges (the ground being previously manured and trenched), measure off the lines and draw the drills in the forenoon, and to leave them open till the afternoon, so that the soil in them may dry a little, and become thereby warmer; then to sow the seeds and cover all up before the evening. The drills vary from 2 feet to 3½ feet apart, according to the rankness or dwarfness of the sorts grown, and the object which the cultivator has in view. In the close lines, Lettuces or Spinach are used as inter-crops, but in the more distant ones Cauliflower is the crop usually planted. Picking is often resorted to, and the more attention paid to this, the longer will the Peas continue to bear. For seeding purposes the Peas in the rows are shifted once or twice from one side to the other, so as to preserve

the pods from rotting with the damp and from being destroyed by snails, and to cause all to ripen alike and well. When the Green Peas arrive in the market, which they do in half bushel baskets, covered with Rhubarb leaves fixed on the surface by means of Willows, and are disposed of to various salesmen, these employ women to shell them in large quantities. All the Peas then, little and big, are sifted; the largest being thus kept separate and freed from all spotted or worm-eaten seeds, are kept in basins by themselves, and sold at a higher rate than the others, which are in their turn re-sifted and picked, until three kinds of Peas are the result. Covent Garden Market is supplied with Green Peas from Algiers as early as March, and from that source, Spain, and Portugal in April and May, and from France in May and June. It would hardly pay the French growers to send us green Peas during the summer time, when our own market gardens and farms glut the market; therefore, what they do not dispose of at home they preserve in small tins for exportation to England during the succeeding winter, and thus it is we see at that season in the salesmen's shops "green Peas at 1s. per tin." Many people are led to imagine that these are freshly picked Peas, but that is a mistake. F.

OUR POTATO CROPS.

MR. BARNES is correct in stating that the Potato disease generally makes its appearance about the beginning of July. I have noticed that it appears about the 9th of July, and always when we have had "thunderstorms followed by cloudy drizzling rain and fog." A thunderstorm occurred this season on the 29th of June, but it was sharp and short, and left no drizzling rain or fog behind it; on the contrary, it cleared away rapidly, and was succeeded by bright sunshine and a nice drying wind, which dried up all the damp from vegetation, and left it in a healthy and growing state. Therefore, in only a few small ill-ventilated gardens, overshadowed by trees, did disease put in an appearance. At least, I have not yet heard of any material damage having been done by it, and I have examined and paid great attention to the Potato crop in numbers of localities, but luckily without finding any disease. I may say, indeed, that as far as the south-west is concerned, there is none at present. And as we still have brilliant sunshine and drying healthy winds, I think we shall escape. I have always been inclined to think that if we could get safe through July, we could keep free from disease; July is pre-eminently the month in which most of our heaviest thunderstorms occur, a fact which goes far to prove that electricity is the cause of the disease. It has been found by passing a strong electrical current through some portions or branches of Willow cuttings, and then planting them, that the electrified portions withered and died, whilst those portions not acted upon grew strong and healthy. It has been stated, moreover, that even small shocks sent through the stem of a Balsam killed it in a few minutes, although no disruption of its parts was visible. The tissues were, however, doubtless acted upon by a too strong current, in such a way that the sap could no longer continue its course, and hence death was the result. This is not, however, always the case when Potato leaves are struck; on the contrary, they often show disruption too plainly and are thus left in a condition favourable for the attacks of insects or Fungi. I have often tried the effect of cutting off the discoloured spot in order to see if the rest of the Potato would remain good; but no, it always decayed. Be the cause of disease, however, what it may, I am heartily glad that our Potato crops are likely to escape this season. I am now writing at the same table at which I sat last year on the 24th of July, the morning after which we had one of the most terrific thunderstorms with which this county has been visited, and on the 25th I visited the Potato fields in this neighbourhood and found them a mass of disease, although one week before they were luxuriant and healthy. I have observed the Potato disease for these forty years past and have, every season, been more and more convinced that the cause of it is electricity. J. SCOTT.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Cattell's Reliance Cabbage.—We have received specimens of this Cabbage cut from a bed in which heads were fit for use in the end of April. It is one of the best early Cabbages we have seen this season.

Onions Splitting.—Having planted a fine bed of Giant Rocca Onions, sown in August last, they grew strong and healthy. I watered them well and regular, frequently giving them a supply of liquid manure. About the first week in July the largest began to split in the centre, forming two bulbs; and now the whole of them are in the same condition. Previous to splitting they averaged sixteen inches in circumference. I likewise sowed some of the same seed in March last, when the Onions grew very large, but, strange to say, they are now dividing, forming two distinct Onions. Can any of your readers inform me whether this is usual? If not, what is the cause?—*GEO. DAVIES, Haverfordwest.*

NOTES OF THE WEEK.

— MR. PEARSON, of Chilwell, is somewhat jubilant in a contemporary on the sufferings of hardy flowers during the present year, and seems gratified that "the advocates of the mixed border have been silent of late." Considering the unusually miserable aspect presented by bedding plants throughout the London district this year we should have thought it the least likely of all seasons to give rise to remarks of this kind. The fact is, that though hardy plants suffered greatly from winter and spring drought and May frosts, the main beauty of our gardens has been afforded by them. The *Yuccas*, now so effective in many gardens, the *Gladioli*, *Arundo conspicua*, *Lilies*, *Irises*, *Daffodils*, *Paeonies*, *Larkspurs*, *Anemones*, *Columbines*, *Harebells*, *Hemerocallis*, *Everlasting Peas*, *Enocheras*, *Phloxes*, *Primroses*, *Ranunculi*, *Rudbeckias*, the *Forget-me-not* family, the *Globe-flowers*, *Speedwells*, *Violets*, *Tritomas*, hardy *Crinums*, *Snowflakes*, *Grape-hyacinths*, not to name a few dozen other charming families of hardy flowers, have afforded us, even in 1874, a feast of beauty compared with which the vast display struggling over the mid-edgings in our London Parks for the last eight weeks is poor indeed. It cannot, moreover, be too often said that the mixed border is but one of many ways in which these and other hardy flowers may be grown.

— WE have received splendid spikes of one or two distinct varieties of *Disa grandiflora* from Sir Wm. Marriott, and grown in his garden at Down House, Dorset. The flowers individually were very large and richly coloured, two or three on a spike, which at a distance looked as if it bore brilliantly coloured *Lilies* of various hues. The foliage accompanying the spikes also resembled that of vigorously-growing *Lilies*. This is one of the most striking of all terrestrial *Orchids*, and rarely seen in anything like perfection.

— LONDON is now, we fear, making preparation for a new danger in the wood and pitch streets now being laid down. At a period when whole cities are laid waste by fire it is, surely, unwise to make the street itself combustible, and, whatever other points a good street paving should possess, non-combustibility should be considered essential. It is frequently supposed that the buildings in Chicago and Boston, burnt by the great fires of the past few years, were built of more combustible materials than ours, but to a very large extent this was not the case. They were often of stone as massive as any in London, and fires of much less intensity would of course, set fire to wood and pitch roadways.

— OUR attention has just been directed to some useful horticultural implements, principally the inventions of Mr. Alfred E. Peirce, of Oxford Street, a well-known exhibitor at most of our leading exhibitions. These consist of tubular iron ladders, which may also be used, if required, as a pair of steps; and some remarkably useful improvements in the way of library, office, and conservatory chairs, which may also be utilised as steps if desired; a new hose-reel, too, deserves general adoption, as, by a simple contrivance it picks up the hose and winds it on the reel or drum at the same time instead of rapidly wearing it out by dragging over the surface of the gravel walks or lawns in the usual way. Mr. Peirce has also introduced the vegetable slicers and Pea-shelling machines, now found so universally useful in America.

— THE large American *Aloe* at Kew, to which we have already alluded, is now in flower. The flower-stem is nearly 20 feet in height and the candelabra-like branches are produced in a lax tapering cone nearly half that length. The lower branches are about 2 feet in length. Large quantities of nectar, attractive to bees and flies, are secreted by the pale wax-like flowers. The plant is supposed to be nearly a century old, and Mr. Croucher informs us that it is a peculiar variety sometimes known in collections as *A. mexicana*, and one which differs from the common American *Aloe*, in the length and disposition of its great fleshy arched leaves. A fine pair of ordinary American *Aloes* is bearing tall spikes just now in the Royal Horticultural Society's conservatory at South Kensington. Of these plants there is a little grove in the great conservatory at Chatsworth where they grow in great luxuriance, and form a characteristic feature in that noble structure.

— THE current number of the *Botanical Magazine* contains coloured plates of *Crinum Moorei*, a stately Amaryllidaceous plant from South Africa which bears great rosy flowers from four to six on a scape; *Brachysema undulatum*, a native of Western Australia, a pretty greenhouse shrub with oblong leaves and deep purple pea-shaped flowers; *Decabelona elegans*, a striking succulent plant from Southern Africa nearly related to *Stapelia*, having branched, spinose, *Euphorbia*-like stems and large drooping tubular or bell-shaped flowers of a yellowish-green colour densely mottled with reddish-brown; *Kniphofia Rooperi*, a charming addition to this genus (*Tritoma*), and one which has flower heads closely resembling those of *T. Uvaria* with much broader bright green foliage. It is a native of South Africa. *Achillea ageritifolia*, a native of Greece, is a dwarf

tufted Composite with linear serrate glaucous foliage and conspicuous creamy-white flowers measuring about an inch across.

— THE *Tigridias*, brilliant but neglected old flowers, are now in fine bloom in Mr. Ware's nurseries at Tottenham. They should find a welcome place in all gardens with warm sandy soil, as in such they frequently survive the winter.

— MR. JOHN GRIGOR, nurseryman, Forres, has given the handsome sum of £1,000 to the funds of Gray's Hospital, Elgin. The Forres Nurseries, of which Mr. Grigor is proprietor, are almost wholly devoted to forest trees and shrubs.

— MR. JOHN WILLS has just now a magnificent display of *Tuberoses* in his nursery in the Annerley Road. About 150 strong potfuls, bearing from four to six spikes each, are arranged on each side of the central path of a span-roofed forcing-house. The flower-spikes, which vary from 4 to 6 feet in height, form an avenue of white fragrant flowers.

— WE understand that a new journal is to be started, in which the interests of horticulture will be partially represented, after the fashion of some existing journals. It is to bear the happy and comprehensive title of the *Handglass and Hencoop Gazette and Daffodil and Duckling Journal*. We wish the new aspirant a brilliant career.

— WE notice in a contemporary some remarks on *Ixora Fraserii*, which fail to do the plant full justice. It is distinct from *I. Williamsii*, and is most decidedly one of the hardiest of the whole group, bearing splendid trusses of rich orange-scarlet flowers amid stout fresh green foliage. It has a vigorous habit of growth, and was raised by Mr. Fraser, who was also the raiser of *I. Williamsii*.

— MESSRS. RIVERS'S orchard-houses at Sawbridgeworth (described by us at length last year), are now in fine condition, and full of interest to all interested in fruit culture and in the raising of new fruits. There are also some fine examples of well and economically-built fruit houses recently erected in those old and well-known nurseries, and all well filled with admirably-grown young Vines and fruit trees of various kinds.

— IT may interest some of our readers to know that the large-berried Liberian Coffee, to which we have previously alluded (see p. 250, Vol. IV.), is now in cultivation at Kew, and Mr. Kennedy, of Covent Garden, has shown us plants of it, growing well in his shop, under glass shades. Mr. W. Bull obtained both seeds and plants of it from Africa, some months ago, and shipped some of his stock to Ceylon, for experimental purposes in that island. It appears to be hardier than *C. arabica*, and the berries, which are twice the size of those of *arabica*, are said to be of a better flavour.

— THE last portion of the Meadowbank collection of plants was disposed of on Wednesday, Thursday, Friday, last and realised good prices. The following are some of the most notable: *Cattleya Dowiana*, £5 5s.; *Anthurium Scherzerianum igneum*, £9 19s. 6d.; *A. S. grandiflorum*, £11 11s.; *Odontoglossum Alexandro niveum*, £6; *O. hystrix superbum*, £6 6s.; *O. radiatum majus*, £7 10s.; *Lælia elegans Turnerii*, £5 15s. 6d.; *L. superbiens*, £9 19s. 6d.; *Epidendrum vitellinum magnificum*, £6 6s.; *Vanda Batemanni gigantea*, £13 13s.; *Angraecum eburneum superbum*, £9 9s.

— THE extent of the culture of early Potatoes in the Channel Islands has been amply shown by the large quantities exported this season. The approximate returns of Potatoes sent from Jersey during the two months ending July 15, represent 22,623 tons, estimated at £215,000. The area of the island is 28,717 acres; and, it would appear, from the above-mentioned figures, that the cultivation of Potatoes alone has realised £7 9s. 8½d. for every acre of ground on it.

— AT the meeting of the Royal Horticultural Society, which was held at South Kensington on Wednesday last, Mr. H. Loder, gardener to H. B. Hennel, Esq., Forest Hill, exhibited one of the most remarkable specimens of *Lilium auratum* we have ever seen. It was growing in an 11-inch pot and consisted of two stems, each about 10 feet high, which, together, bore sixty-five flowers. This plant has been produced by a single bulb, and, if it may be taken as a specimen of what may be done with other *Lilies* by skillful cultivation, much more striking effects may be expected from this class of plants than have ever yet been realised.

— WE have received from Mr. Knight, of Floors Castle, magnificent blooms of the double pink-flowered *Oleander*, an old-fashioned plant it is true, but one seldom seen bearing flowers possessing half the beauty of those sent. They were cut from a plant, Mr. Knight informs us, planted out in a heavy soil and grown in a natural Willow-like manner. He has also, however, he admits, on two and three year-old plants, blooms equally fine. It is a suitable plant for cool corridors, in which it succeeds perfectly at Floors. Two fine specimens in Mr. Peacock's collection at Hamme-Smith are just now in great beauty, and the flowers are valued for cutting.

THE GARDEN IN THE HOUSE.

DINNER-TABLE DECORATION.

Preparing Flowers.

WHERE flowers are wanted to last for any length of time, much depends on the manner in which they have been prepared. Take, for example, a stand in which a truss of Pelargonium or a Camellia occupies a prominent position, how provoking it is, after the last finishing touches have been given, and it is being removed to the position it is to occupy, when first one petal begins to drop, then another, and, finally, down comes a little shower, and nothing is left of one's Pelargoniums or Camellias but the stems. This I have seen often occur; but, by careful preparation, it can be easily avoided. The first thing to avoid are flowers which have been grown in a high temperature and where the plants have not been well hardened off before they were cut, and the same remark applies to Ferns, for, if the fronds are cut for use while the plants themselves are growing in the stove, they will shrivel up in about an hour after having been cut. In cutting, the stems of both flowers and Ferns should be severed with a sharp knife and not with scissors, as is generally done. By using a knife no bruising takes place, and the stems are better able to imbibe moisture, so as to keep them fresh. When arranging flowers it is a good plan to have a basin of water close at hand, and before each Fern frond is placed in the position in which it is to remain to dip it into the water, lift it out, and give it a gentle shake. This will apparently remove the water from the leaflets, but a number of globules will remain on them, though not observable to the naked eye, which will tend to keep them fresh. The water should be tepid, *i.e.*, just the chill taken off.

Wiring Flowers.

Many flowers, in order to keep them from falling to pieces, must be wired, an operation by means of which the stems can be bent into any required position. The different kinds of wires for this purpose may be obtained in the Central Avenue, Covent Garden Market. Of these, I use four kinds, viz., two sizes of piercing wire, stubs, and bending wire. The three former are sold in bundles, cut in lengths, and the latter in reels. The piercing wire is that with which the different parts of a flower are sewn together; the stubs are used as artificial stems to flowers such as Camellias, which are cut off short, and the bending wire, is that with which the flowers are bound to the stubs. Such numbers of flowers require to be wired, it would be impossible to enumerate them all, or describe the mode of doing each; I shall, therefore, select a few of those in most common use, and endeavour to clearly describe the process of wiring them. I ought to have added, that a light pair of wire cutters will be necessary to cut off all surplus ends; these may be obtained of any ironmonger, and the smaller and lighter they are the better, and both these and the wire should be kept in a small box in a dry place, so as to prevent them becoming rusty. Let us begin with the Camellia, a flower employed in all descriptions of floral decoration. Suppose a box full of Camellia blooms was sent from some nursery, they would be found to have been cut off without stems, and to make an artificial stalk, as well as to prevent the petals dropping, wiring must be resorted to.

Let the bloom be lifted with the right hand, invert it, *i.e.*, turn it face downwards and gently press it as if one were trying to fold the bloom in two; this, however, must be done very gently so as not to bruise the petals, or the flower will be spoilt; it should then be held in that form between the first finger and thumb of the left hand, and a single wire, the strongest of the piercing kind should be run through its centre sufficiently deep to catch all the petals in the line in which it is inserted, but so as not to show in the centre of the flower when turned up. The bloom should then be half-turned round, pressed again in the manner just described, and another wire should be pushed through it, this one being put in so as to cross the other, and so on until four wires have been inserted, as shown in the accompanying illustration; then all the points of the wires should be bent back until they meet, and being taken hold of by the right hand, should be drawn down between the first finger and thumb of the left hand, close to the palm: even after the back of the bloom has come in contact with the hand the wires should still be drawn down a little; but very gently, an operation which presses the petals into their proper places. The wires should next be drawn close together and one of them twisted round the others in order to keep them firm, and form a slight stem, which should be bound to a stub with some reel wire, a little damp Moss being bound in close to the flower so as to help to keep it fresh. The stem may then be cut as short as may be required, and the mounting of the

flower is finished. Now let us take a spike of Hyacinth. This, in its natural state, is anything but useful for floral decoration, but if the pips be picked off and properly mounted they will be found to be excellent for many purposes, varying, as they do, so much in colour. Each pip should be pierced by two wires (crossing each other in the centre) of the finest piercing wire, the pip being held stem upwards between the first finger and thumb of the left hand; the four points of the wire should then be bent backwards and twisted together in the form of a stem. The pips may thus be mounted on a stem singly or six twisted together, and then bound on to each stub. In just the same manner as the Hyacinth, are mounted the pips of Stephanotis. Bouvardias are, however, treated differently. These have long slender white tubes, which, if bruised or cracked in the least, soon turn brown, which of course spoils their beauty. The stem or rather the branch, for several blooms are on each spray of the Bouvardia, should be held in the left hand, and into the centre of each open bloom and down the tube should be run one of the fine piercing-wires; and, as soon as the bottom of the tube is reached, the wire should get a gentle push, so that the point may become inserted in the stem at the base of the tube. A pair of sharp scissors should then be taken and the wire cut off in a line with the centre of the flower. The wire is

never noticed, and it forms a support to the tube and keeps the flower in an upright position. These examples of wiring must suffice, though Orchids, Roses, and many other flowers all require that treatment, into the details of which, individually, it is, however, impossible to enter.

Gumming Flowers.

This is another operation to which attention must be directed, as many flowers not wired require to be gummed,

Bouvardia.

1. Camellia. 2. Laurel-leaf background. 3. Hyacinth pip.

and some require both gumming and wiring; for instance, the *Bouvardia* amongst others. Common gum will not answer; it must be prepared by one's self or bought, which it can be quite as cheaply as it can be made at home. The gum should be always applied by means of a small paint-brush. First, let us take a *Pelargonium* as an example of one of the flowers which should be gummed. (Gum the point of the paint-brush, and into the centre of each bloom should be dropped one drop of gum, which should be dropped so as to fall into the very centre of the blossom. Each truss, as soon as gummed, should be laid on one side before being placed in water so as to dry a little; for the gum, being made of spirits, quickly evaporates. Primulas and several other flowers are gummed in this manner. I shall, therefore, leave my readers to pick out such flowers as should be gummed in this style and advert to such as require to be done in quite a different way. The *Bouvardia* and *Azalea* both, in place of having the gum dropped into the centre of the flower, like *Pelargoniums*, should be gummed outside, the gum being painted on with the brush where the flowers and stem join. To gum flowers neatly and well takes some little time and trouble, but there are several flowers which, if not prepared in this manner, would be otherwise almost useless; for, as soon as arranged, their petals would begin to drop. As with flowers which require to be wired, the selection of those that require to be gummed must be left to one's own discretion.

Keeping Prepared Flowers Fresh.

The best way of keeping flowers fresh after they have been prepared is to place their stems in water, and then to put away the vessels containing them in some dark cool cellar until required for use. Ferns should be kept laying in a pail of water, or else be well saturated in water and then shut up in an air-tight tin canister. In the latter way they will keep for days as fresh as if only just cut off the parent plant.

A. HASSARD.

THE INDOOR GARDEN.

THE GESNERA-FLOWERED SAGE.

(*SALVIA GESNERIFLORA*.)

In the last number of *THE GARDEN* (p. 100) there appears a note respecting this *Salvia*, which, when well grown, is truly a splendid plant for the conservatory, and one in the culture of which I have been most successful. My plan has been to grow fresh plants every year, and to throw the old ones away, after sufficient cuttings have been taken and the blooming over. The cuttings are taken in March or early in April, according to circumstances. Each cutting is placed separately in a large thumb pot, plunged in a slight bottom-heat, and, when necessary, they are shaded from the sun. After they are fairly rooted, they are stopped back to two pairs of leaves, which causes them to put forth four shoots, and thus to form a good foundation for the future plant. After these shoots are fairly started, I shift the plants into 48-sized pots; then, after they have made a little growth, I stop again, as before. They should have plenty of water, and should be kept until about the middle of May in a genial growing temperature, but not too high, as that would induce weak growth. About this time I remove them to a frame for a month to gradually harden them, but I still keep them steadily progressing in growth until about the middle of June, when they are planted in the open ground in a sunny position, but sheltered from boisterous winds, from which they are liable to suffer. The ground should be well enriched with good rotten manure. If very large plants are wanted, plant them out 4 feet apart every way; and, if they are properly attended to, they will more than touch each other by the time they should be taken up in autumn. After having been planted out some little time they should receive another general stopping; but, after that, only a shoot here and there should be stopped, so as to make the plants symmetrical in form. After that they should be left alone with the exception of attending to them with water should the season prove dry. Each main shoot should be carefully secured to a stake, for they are very apt to break off at the point of juncture with the

main stem, when the plants become badly disfigured. The stakes should be placed so that when the plants are lifted for potting they may be moved with them undisturbed. As this, like other *Salvias*, is liable to be injured by early autumnal frosts, care must be taken to lift all plants of it sufficiently early to escape them. They should be taken up with large balls of earth and potted into large pots, using for that purpose good rich soil. After they are potted they should be thoroughly watered and then placed in a pit or cool greenhouse, and kept close for about ten days or so, giving them plenty of water, with a syringing overhead every day, until they have made fresh roots, which, if thus treated, they will quickly do. During the winter months they should be kept in a light airy greenhouse, and, thus treated, they will produce flowers on every shoot in March and April, without any forcing, making splendid objects for the conservatory; they are also very useful for cutting, though I find that the flowers are not favourites in Covent Garden. By the mode of culture just described plants may be grown as large as good-sized Currant bushes; to anyone who has never grown this *Salvia* in this way, I can only say try it, and I have no hesitation in asserting that whoever does so will be amply gratified with the result. Anyone having young plants of it may even now plant them out, and by careful tending they will make nice bushes before the autumnal frosts set in, the growth being very rapid during August and September.

Willow Lodge, Mitcham.

H. A. WOOD.

CULTIVATION OF THE CHINESE PRIMROSE.

The cultivation of this Primrose is gradually becoming better understood, as is demonstrated by the higher character of the plants staged at public exhibitions. There, however, yet appears to be plenty of room for farther improvement. It is not needful to speak of the value of these flowers for the decoration of the conservatory; but I would observe, in passing, that they are quite unsurpassed for that purpose; and, further, that no other class of plants producing as good a display of colour can be grown with so little trouble and expense. I am now referring to the single varieties, which possess the important advantages, over and above the double forms, of being readily raised to an unlimited extent from seed, and of possessing a more vigorous growth. The double varieties are extremely beautiful, I am perfectly willing to admit, and well worthy of the attention of those who possess the requisite skill, and are able to afford the proper accommodation for their successful cultivation; but, for the great body of gardeners, they are of but little practical value. Their increase by cuttings is a slow and tedious affair, they are rather "miffy," and seldom last in good condition more than two years; and, when all is said and done, they are not a whit more effective in the conservatory than the single forms.

Seed, and Time for Sowing it.

One of the most important matters is to obtain thoroughly good seed, or, to speak more plainly, seed saved from a thoroughly good strain. The selection of the colour of the varieties to be grown may be left to individual taste, so long as the seed has been saved from flowers large in size, of good form, stout in substance, and rich in colour; or, in the case of the white flowers, quite pure. For general decoration the ordinary crimson and white varieties are the most suitable. We grow here crimson and white varieties representing two strains I have for many years endeavoured to maintain in the highest perfection, as well as the *Marquis of Lorne* and *Princess Louise*, crimson and white strains, introduced into cultivation two or three years since. The two strains known under these distinctive names are wonderfully good, and seed obtained from true stocks may be sown with the full assurance that a large percentage of the seedlings will have flowers of the finest quality. To maintain a continuous supply of flowers from early in the autumn until late in the spring, it will be necessary to make two sowings, for the plants coming into bloom first will not continue in good condition throughout the season. The most suitable periods for sowing are the early part of June and the beginning of August; the first for the production of plants which will commence to bloom in the first week of November and onwards, and the second a stock that will begin to show their flowers in January or February. Sow in pans or pots of a convenient size, which have been previously prepared by placing a good layer of crocks in the bottom, and filling with a light and rather rich mixture. The soil must be made quite fine to admit of the seedlings being readily pricked off. The surface should be perfectly level, so that all the seed be buried precisely the same depth, and the soil should be

used in a nice moist condition to render heavy waterings unnecessary; for the seed must have a thin covering only, and if this is disturbed in watering, as will be the case if at all heavy, a portion will be laid bare and probably perish. Let the seed be sown thinly, for the purpose of avoiding the necessity of pricking off the young plants before they have acquired sufficient strength to admit of their being handled without difficulty. Cover lightly, and after a light sprinkle of water place the seed pots in a closed frame fixed in a pit, in much the same manner as advised for *Cinerarias*. The seed will germinate more readily if the temperature is rather in excess of that required for *Cinerarias*, and, to afford it every assistance in that respect, keep the pit-lights closed, and only cover them immediately over the frame in which the seed pots are put. The seed germinates readily in a temperature of 60° or 65°, and there will be no difficulty at this season of the year in providing a temperature sufficiently high.

Treatment of Seedlings.

As the seedlings begin to make their appearance above the surface commence to admit a little air. First tilt the cover of the frame, and in a day or two afterwards ventilate the pit also, and employ less shading. When of a convenient size for handling, prepare a sufficient number of ordinary seed-pans, place an inch layer of crocks in the bottom, and fill rather firmly with the compost that will be hereafter recommended. Make the surface level, and prick out the seedlings an inch or so apart each way. Return them to the pot in which the seed was raised, keep rather close and shaded for the first week or so, and then increase the ventilation. In a fortnight they will have become sufficiently established to admit of their removal with advantage to a cold frame, which will be found the most suitable quarters for the plants until the autumn. When strong and well-established, pot them separately in 3-inch pots, and again keep close for a week or so, to prevent their receiving a material check from the removal. From these they must be shifted into 5-inch pots as soon as they are well-established, but before they become pot-bound; and when these are well filled with roots, transfer to the pots in which they are to bloom. A portion of the stock, if required in bloom as early as possible, may remain in the 5-inch pots, and the others should be shifted into 6 or 8-inch pots, according to the purpose for which they may be required. For the conservatory 6-inch pots will be sufficient, but for exhibition specimens the larger size will be the most suitable, as small plants are of but little use on the exhibition table. I am here speaking generally, but, to avoid any misunderstanding upon this point, I would observe that for the early autumn exhibitions they must not be put in pots exceeding 6 inches in diameter; those shifted into a larger size should have the first flower-truss nipped out to promote the production of a side growth and larger heads of flowers. When this is done the season of flowering is delayed by a period of five or six weeks. Indeed, excepting for the spring exhibitions, 8-inch pots are not required.

Compost and Potting.

A prime necessity in *Primula* culture is a moderately open and comparatively rich compost. In practice I have found nothing better than a mixture of three parts mellow loam, full of fibrous matter, and one part of leaf-mould and thoroughly-decayed cow-manure in equal proportions. The loam will require breaking up moderately, and after the loam and leaf-mould have been well incorporated with it, add a liberal proportion of silver-sand—just sufficient, in fact, to make the compost feel gritty. A very fine compost is not desirable, neither is one too rough; but, to a certain extent, the larger the size of the pot the rougher may the compost be used. It will not be needful to dwell upon the manner in which the plants should be shifted from one pot to another, but it may be useful to many amateurs to know that the soil must be pressed moderately firm without being made hard. The pots must be perfectly clean and the drainage perfect. The latter is of great importance to facilitate the escape of superfluous moisture, and thus prevent the possibility of any injury arising from sourness of the soil through the superfluous water not being able to escape so quickly as could be desired. The pots must also be placed on a bed of rather rough coal-ashes when in the cold frame, for the double purpose of preventing the worms entering the pots and enabling the water to soak away readily.

General management.

Air-giving, shading, and watering constitute the principal points in the general management of the stock. Abundant ventilation until the end of September is of the utmost importance; afterwards, sufficient air to ensure a fresh and healthy atmosphere will be needful. If they are kept in close frames for any length of time, the leaf-stalks will lengthen at a tremendous rate, and by-and-bye the flowers will be embedded in the foliage, and partly out of sight, instead of being borne well above it in bold well-developed trusses. The frames

should be ventilated night and day, until the nights become cold and frosty. During the months of June, July, and August, the plants will require to be screened from the sun; and, as a rule, it will suffice to lay a mat over the lights during the middle of the day, when the sun is shining brightly. With reference to watering, it will suffice to say that rather liberal supplies will be required until the end of September, and after that period more moderately. As the plants continue to grow freely throughout the winter when managed properly, they must have sufficient water to maintain that growth; but over-watering must be specially guarded against. The largest measure of success will be ensured by maintaining the soil in a moderately moist condition; and in watering, whether in winter or summer, applying sufficient to thoroughly moisten the ball. As with the *Calceolarias* and *Cinerarias*, I would strongly advise the inexperienced to avoid the use of stimulants. They are quite unnecessary, and may prove extremely hurtful; and it may be safely assumed that soft water alone will suffice for the requirements of the plants. A cold frame has been already suggested as being most suitable for the summer quarters of the stock; and it now remains to be said that, for the winter quarters, a light airy house will be in every way suitable. The temperature most conducive to a healthy growth, when the plants are in the house, is one ranging between 15° and 50°. Those in bloom will do well in the ordinary temperature of the conservatory; but the stock raised from the last sowing will require sufficient warmth to maintain a steady growth, and that will be afforded them by the temperature I have here suggested. The practice of keeping the plants a second year is objectionable; for they very frequently, towards the autumn, decay at the base and perish, and consequently disappoint the cultivator. Even if they remain in comparatively good health, they do not present the fresh and vigorous condition of yearlings. [The preceding remarks, taken from the *Gardeners' Magazine*, represent the experience of Mr. James, of Isleworth, an excellent cultivator of Chinese *Primulas*.—ED.]

THE LIBRARY.

A PLEA FOR PEASANT PROPRIETORS.*

THIS work is devoted to a consideration of the advantages which are thought to belong to small holdings, both in this and other countries; and holders of small pieces of land in Belgium and in the Channel Islands are brought forth as examples for our imitation in this way. Into the merits of small *versus* large farms it is not our province to enter. Mr. Thornton maintains that small holdings are the most productive. Such holdings, doubtless, tend to encourage industry, and it is on that account quite as much as on account of their produce that allotments are of so much value to our farm labourers. In order to accumulate evidence to this effect, he says, "It is only necessary to turn to any country in which the peasantry cultivate their own lands. Such is the case in Zurich, as well as in several other Swiss Cantons; and, accordingly, says Inglis, 'Anywhere in the neighbourhood of Zurich, in looking to the right or the left, one is struck with the extraordinary industry of the inhabitants. In the industry they show in the cultivation of the land, I may safely say they are unrivalled. When I used to open my casement between four or five in the morning to look out upon the lake and the distant Alps, I saw the labourer in the fields; and when I returned from an evening walk, long after sunset, as late perhaps as half-past eight, there was the labourer mowing his Grass or tying up his Vines. But there are other and better evidences of the industry of the Zurichers than merely seeing them late and early at work. It is impossible to look at a field, a garden, a hedge, scarcely even a tree, a flower, or a vegetable, without perceiving proofs of the extreme care and industry that are bestowed upon the cultivation of the soil. If, for example, a path leads through or by the side of a field of grain, the Corn is not, as in England, permitted to hang over the path, exposed to be pulled or trodden down by every passer-by; it is everywhere bounded by a fence; stakes are placed at intervals of about a yard, and about 2 and 4 feet from the ground boughs of trees are passed longitudinally along. If you look into a field towards evening where there are large beds of Cauliflower or Cabbage, you will find that every single plant has been watered. In the gardens, which around Zurich are extremely large, the most punctilious care is evinced in every production that grows. The vegetables are planted with seemingly mathematical accuracy; not a single weed is to be seen, nor a single stone. Plants are not earthed up as with us, but are placed in small hollows, into each of which a little manure is put, and each plant is watered daily.'"

*"A Plea for Peasant Proprietors." By W. T. Thornton, C.B.; Macmillan & Co., London 1874.

THE FLOWER GARDEN.

WILD FLOWERS AROUND ARUNDEL.

THOSE who have never studied England's wild flowers will probably be astonished to be told that the Stock, the Carnation, the crimson Peony, the Columbine, and the Poets' Narcissus, are, every one of them, with a hundred others, "Ancient Britons," though, owing to the slaughter made by the plough and other instruments of civilisation, they no longer occur in a wild state. The fact is that a hundred, at the very least, of our beloved and cherished garden flowers are indigenous to the woods and meadows of our own island; so that the distinction sometimes drawn between garden flowers and wild flowers is sheer nonsense; the only allowable one is, between exotics and native or indigenous plants. I have also heard it objected to "wild flowers," that they wither so soon when compared with garden ones. Does the Lily of the Valley, which is English, wither any sooner than the Geranium of the Cape of Good Hope? The comparison is most unjust. Taken score for score, just as they come to hand, I am sure the flowers indigenous to England endure as long as the flowers of any other country. Those brought from foreign lands have generally been selected ones, and were we to select English ones, I am confident we should never lose by the comparison. I find bouquets of wild flowers keep, on the average, quite as well as bouquets of garden flowers, that is to say garden flowers of purely exotic origin; and were the matter pushed to a crucial trial I am almost persuaded that English flowers would win. That many English wild flowers are insignificant, is quite true; so are many of the flowers of any other country. Those which are brought to us for the decoration of our gardens are, as just now said, the selected ones of their several homes; were the flora of the very richest spot transported hither faithfully—a specimen of every species—depend upon it we should find quite as large a proportion, which, after the novelty had passed away, we should care no longer to propagate or keep. When, accordingly, I say that a man who loves his garden for the sake of the plants that are in it, and not merely for its *coup d'œil*, which is a very ignoble love; is delighted, at the same time, with the sight of the wild flowers of the fields and woods, I refer to that section of them which an emissary from the Antipodes—supposing that England were a sort of "South Sea Islands" to him—would collect for remission to his employers. Just suppose, for a moment, that the perfection of civilisation lay in this current 1874, as the growth of a dozen centuries, not in Great Britain, but in New Zealand! What pleasure a collector from the "Royal Horticultural" of the place, or from the Veitchs, or the Rollissons, would take in our Water Lilies, our scarlet Poppies, our yellow wood Nettle, our blue Campanulas. To him these would be as great a rapture as the New Zealand plants were to Englishmen when first brought over; and it seems to me that every Englishman should, in these intelligent days, find them no less a rapture to himself. In the neighbourhood of Arundel there is, apparently, as large a scope for the observation of the best description of English wild flowers as can exist in any part of the three kingdoms. It is peculiarly fortunate in the possession, at once, of high downs, which in many parts are covered with trees; extensive chalk quarries, some of which are worked no longer, and where Nature reigns triumphant; a tidal river, on the banks of which sub-maritime plants grow freely and happily; and numerous little water-courses, which, from some cause or other, seem the home of all sorts of curious aquatics. Add to these the sea-shore, distant only some four or five miles, and it will easily be understood that, in diversity of habitat, it is scarcely possible for any place in England to excel Arundel. Beginning with the downs, here we have that beautiful plant the Musk Thistle, *Carduus nutans*, a fit ornament for the rough or rockery portion of any large garden. In my own garden I have it at present in full flower, the noble crimson heads $2\frac{1}{2}$ inches across, and, as implied in the technical name, in the evening scented like musk. The presence of this particular perfume in plants and flowers is very remarkable, seeing that,

in its intensity, the odour is one associated with a little animal, though it is not without some curious parallels; the Hound's-tongue evolving the scent of mice, while Herb Robert smells like foxes, and the Coriander plant like the most abominable of household vermin. Here too, on the downs grows the Sweet Briar, the round cups of the most exquisite pink; while the turf is in many parts quite lilac with the delicate bloom of the little Quinsey-weed, *Asperula cynanchica*, the colour so like that of the officinal Valerian, that one might fancy each laid on while the palette was wet for the other. I make no mention of the unspeakable effect of the Wild Thyme, nor of the innumerable Golden Cistus, for these, though good, are among the "common things;" we find them at all events, in a hundred places where the former do not occur. Here and there may be gathered the Bee Orchis and Fly Orchis. How pleasant it is to see that old England is never behindhand, when, excepting the Palms and one or two others, a natural order of any magnitude wants illustrating in the completest manner. Trinidad may boast of its Papilio, and Brazil of its Frog Orchis, but, as long as we have our English Ophrydes, we may venture to compete in oddities with all the world. Another very lovely Orchis, not uncommon at Arundel, is the crimson *Pyramidalis*; while, in the woods, where it is damp and shady, they have the Twayblade, and occasionally, under Beech trees, the *Nidus avis*. The Twayblade was the first Orchis that I learned, when, as a lad of thirteen, I started on the botanical pilgrimage that every day since that time has become more delightful and rewarding. Hence I look upon it still as one of the little blessings of my life; for, depend upon it, though money is useful, and learning brings reputation, the things that a man has most reason to be thankful for, are the unconsidered ones that, in his boyhood became key-notes to the inmost pleasures of his existence, providing him with pastime when everything else became a weariness and a trial. To have a secret source of pleasure that we can fall back upon under every circumstance and in all conditions, that comes fresh and fresh to the heart every year, and that daily becomes more solid and substantial, is assuredly no slight privilege. Every man may command such a one, if he will only begin early enough; and I believe that none will prove more true of its kind than botany. Shall I ever forget my Twayblade when transplanted from its native woodland into my garden, the buds only half-expanded, morning after morning I lay down upon the turf to count the increase, and watch the progress, every quaint little flower, a fairy's head above, two long green legs below, seeming to say to me, *i.e.*, if I properly understood its language, "Love me, and I will love you." Shall I ever forget, either, how, in due time (slowly, slowly, but patiently waited for), at last came on my Twayblade those beautiful little green spheres, the seed-pods, totally unlike anything else I had ever seen, bursting in beautiful meridians like those on my globe in the school-room. Forgive me, gentle reader, if I am tiresome. Ask yourself what sweet thing, when you were yourself a child, made a little heaven to your imagination, and has never died away from your private memory, but lives there still, like a first love, and you will understand what the Twayblade is to my own. In one of the woods where these plants occur, I noted, for the first time in my experience, the Polypody growing upon the boughs of an aged Elm tree. That this beautiful Fern, the *Chrysophylla* of old England (for how golden are its abounding spangles), perches itself very commonly upon old Oak trees, is known to everyone who in the woods lifts up his eyes. It may grow quite as freely upon other trees; I do not know how this may be, and merely record the fact of its abode upon the Elm as new to my own observing. Anyhow, what a capital idea it gives one of a *bona fide* epiphyte! Mosses and Lichens are too small; the Mistletoe is a parasite; Ivy is neither one nor the other, having its roots in the ground; the Polypody, in its way, is perfect as an illustration. Mistletoe, I may remark, occurs upon the Limes at Parham, a place so rich in ancient and noble trees, especially Oaks, that an artist may study some new and glorious form every hour for the space of a week. Everywhere about Arundel, the trees are glorious. In the Park there are Maples, very many larger and more beautiful than I have ever seen elsewhere. Here too, is a Hazel, the common *Corylus Avellana*, with a trunk that might

be sawn into planks, and a Cherry so big that it seems a remnant of the heroic ages. Most remarkable of all perhaps is a Spanish Chestnut at Friar's Lee, the massive trunk of which presents the appearance of having been spirally twisted by the hands of a Titan. From base to summit the stem of this wonderful Chestnut is wreathed round and round, in the most beautiful manner, with deep spiral fissures and corresponding elevations, that remind one of the apprentice's pillar in Roslyn Chapel, the pattern a dozen times repeated.

In the chalk quarries near Arundel, especially those about Burpham, grow many distinguished plants. Among the most noticeable are the narrow-leaved Willow-herb, so great a favourite in suburban gardens, the sky-blue Echium, the Lady's fingers (*Anthyllis Vulneraria*), the little palmate bracts of which, one to every head of flowers, suggest the idea of an open hand; the sweet Melilot, which when dry, smells like new-made hay; that grand Centaurea, which, from its likeness to another handsome plant, goes shares with it in the appellation *Scabiosa*; the great white Galium Mollugo, the golden Oat-grass (*Trisetum flavescens*), and, over again, the *Orchis pyramidalis*. Less conspicuous but very charming wild flowers inhabit the same place in profusion; while, in the neighbouring hedges are the Bryony, the Tamus, the Woodbine, Privet—so fine and luxuriant, that one is tempted to call it the English *Syringa Emodi*; and, above all, the loveliest Roses that ever grew. It is in the immediate neighbourhood of the Burpham Quarries that many of the best aquatics are to be gathered, the little water-courses that intersect the meadows teeming with the rosy umbels of the *Butomus*; while here and there are patches of the Water-*Arrow-leaf* (*Sagittaria sagittifolia*); and, as to the more usual plants, there is everything you like to ask for—from *Cenanthe fistulosa* and Frogbit down to Reeds. Abundance of water-plants may be found also in Swanbourne Lake, the ornamental water at the lower extremity of the park. Here flourish the Water Lilies, sundry *Potamogetons*, the *Ranunculus circinatus*, and the *Myriophyllum*; while, on the margins, mingled with various cosmopolites, grows the *Cladium mariscus*. In the lanes, in various directions, especially towards Amberley, a beautiful spectacle is presented by the *Lathyrus sylvestris*—the original form, so it would seem, of the Everlasting Pea of the gardens. Here, too, I note the curious anomaly of *Cardus palustris* towering high among the bloom of the Brambles. As for such plants—never to be beaten—as the Hart's Tongue, the Meadow-sweet, and the Poets' Forget-me-not, they attain a degree of luxuriance at Arundel quite astonishing. But I must not presume farther on your space. To exhaust my list, I should have to enumerate something like the half of our British flora, and certainly the half that is worthiest for sweetness and beauty. I have said nothing, for instance, about the Mouse-ear Hawkweed, that smells like Raspberry jam; nor about the Silver Plantain, nor about the Teasel, the *Nepenthes* of our native plants, just as the Pellitory, here quite as plentiful, is our English "artillery plant." The Foxglove also is here, and the Plough-

man's Spikenard, and the lovely lilac *Knautia*, that turns green in the smoke of a cigar; the St. John's Wort, too, that is so like the Golden-rod, and the Loose-strife, and the Bugloss, with companions in the *Chlora* and the *Erythraea*, so clear in their delicate hues, and so sensitive, withal, to the sunbeam—opening when it shines, shutting up when it departs. At the time of my visit the Furze was brown; but truly splendid, in its season, must have been the display. Of Bluebells and Primroses, also, there were but vestiges—enough, however, to show that Arundel is the same in spring as in high summer. I do not wish to assume that Arundel beats all other places in regard to its wild flowers. Possibly other parts of the sunny south are quite as rich. I seek merely to indicate how wealthy it is in the simple and everlasting charms of Nature—the too often unconsidered elements that have made our country a fitting home for refined taste. The scenery is on a par, and there live at Arundel those who are worthy of it. G.

A MOVEABLE IVY BOWER.

THE accompanying is an illustration of a moveable tent, or sun-shade, formed of Ivy, which was exhibited at the Paris Exhi-

A moveable Ivy Bower.

bition of 1867, and the plant of which it is formed has now a straight, clean stem more than 6 feet in height. The spread of the branches, if fully extended, would be about 10 metres (between 32 and 33 feet), but they are trained in an arching manner so as to leave an opening about 7 metres (about 23 feet) in diameter. The branches are well furnished with leaves, and, as the plant is grown in a tub, it can be removed from place to place, as may be required, and may be made to serve as a most agree-

able summer-house. The facility of transport is still further increased by the fact that the branches are trained over wires which can be folded up umbrella-fashion. The plant is now in the possession of M. Roussel, landscape gardener, 16, Chaussée du Maine, Paris, but we are not informed to whose patient skill we are indebted for the work of training it in its present fashion. Many similar tents might be made with other kinds of plants, such as Virginian Creeper, Common Kidney Bean, Hops, and other plants that grow much quicker than Ivy, but in that case instead of a central stem, the pots containing them would have to be set on the outside of the circle and the plants trained over a canopy formed of wire or woodwork.—*Revue Horticole*.

Nertera depressa.—Mr. Barron grows this pretty little plant at Chiswick, planted on the surface of a shallow pan, like *Selaginella*, filled with fibrous peat, turfy loam, and leaf-mould. At a recent meeting, two pans of it were exhibited, reminding one of pans of *Selaginella*, or of Stone-crop strewn with coral beads. The plant has a very wide geographical distribution, being found at elevated altitudes in the Falkland Isles, Cape Horn, on the mountains of New Zealand, and in Tasmania, as well as in the Campbell Islands, and other places in both hemispheres. It is quite hardy in sheltered positions on rock-work, and grows freely during the summer months.

To see it to advantage, however, it should be grown in a cool moist house or pit, and liberally supplied with water at the root. It is seldom seen in cultivation, although it is extremely interesting even when treated as a window plant in a north or north-western aspect. It also grows well in a Wardian case, in which it runs over the surface of the compost like bright green Moss. It is rare to see it in nurseries, although it has been in the country for many years.—B.

NOTES FROM THE LEVANT.

(Concluded from p. 91.)

In returning from Macri to Smyrna, overland, a distance of about 250 miles on horseback, I passed through, what I believe, is some of the most beautiful country in Asia Minor, varied with wood, water, mountains and plains, in such a way that it reminded me of places in Scotland. I was, however, so pressed for time, that I could not stop much to collect plants, though I took a few of the best of those I saw by the roadside. Among them were no less than three species of *Fritillaria*, namely, *F. Pinardi*, *F. Græca*, and one which I think is *F. acmopetala* (Boiss.). The two former are very dwarf species, with yellow flowers, spotted and blotched with purple; the latter was a much taller one with large dark coloured bells.* I noticed that of these *Fritillarias*, not more than a small proportion of roots flower, the rest producing only ovate radical leaves like those of a seedling. These bulbs, though often stronger and larger than those that had produced a flowering stem, were small compared to the bulbs of cultivated *Fritillarias*; and often very deep in the ground, among stones and roots. Near the spot where Sir Harry Jones was shot by brigands some years ago, I found a pretty Tulip in flower, *Tulipa undulatifolia* (?), but I was still too early for some of the best plants. In the high plains round Moolah, a very striking yellow-flowered plant, *Leontice leontopetalum*, was coming up in abundance in the fields. This is a plant worth looking after by gardeners, as it would be perfectly hardy in England, and from its size and time of flowering, a fit companion in the herbaceous border for *Dielytra spectabilis*. *Paronychia argentea*, a beautiful silvery trailing plant, grew abundantly in some of the rocky Pine woods. I also got several more Orchids, among them, *Serapias longipetala* and *lingua*. *Orchis undulatifolia* and *longicorne*. On arriving at Smyrna after an unusually quick journey, I found my plants, though a good deal scorched by the hot sun and shaken by the constant jolting of the horses, were still mostly alive, and having sent off some boxes of them to different friends, I determined to spend the next week in a trip to the Bozdagh, a range of mountains which run from Cassabar as far as Alashehr, and reach at least 6,000 feet of elevation.

The market gardens at Smyrna were now at their best, and produced abundant crops of excellent Lettuces, Onions, Beans, and Artichokes; Peas are not much grown, as the climate is too dry, neither did I see Currants, Gooseberries, or Strawberries, except in a few private gardens at Bournabat. The gardens at Bournabat are somewhat celebrated in the Levant, but though they contain many fine trees and shrubs, I was disappointed both with their contents and arrangement. Loquats, Oranges, *Crataegus glabra*, *Pittosporum*, Pepper trees, Cypress, Judas trees, Myrtle, *Enonymus*, and a large-leaved species of Box, are their principal ornaments in the way of trees; but the flowers were a poor show, considering what they might be in such a climate. *Eucalyptus globulus* has been planted freely here within the last six years, and grows rapidly, but the Cypress is certainly the finest tree anywhere round Smyrna. Bedding out is practised to a certain extent in the English gardens, but no use at all has been made of the numerous indigenous plants which would be thought so much of in England. I was assured that Hyacinths would hardly grow at Smyrna, which I thought strange, considering that they are indigenous; but gardeners in the Levant have still much to learn with regard to the cultivation of flowers. On my way up to Cassabar I stopped at Manisa, and ascended the mountain at the back of that town, which is between 4,000 and 5,000 feet high. Here, many trees and plants which I had not seen in Lycia were common, especially

Paeonies, Hollyhocks, Aubretia, Alyssum, and other well-known garden plants. I found a species of yellow Crocus, with corm of the biflorus type, in great abundance at about 4,000 feet, together with *Scilla bifolia*, a hairy-leaved species of *Gagea* or *Ornithogalum*, and a curious looking vernal Colchicum, *C. Steveni*. Apples, Apricots, Peaches, Cherries, and Vines, are cultivated largely to an elevation of at least 2,500 feet, and were, at this time, covered with blossom. The Turks and Greeks have an immense number of different varieties of fruits, many of which would be well worth growing in England. Apples were now, at the end of April, cheap and excellent, and I was assured that some of them would keep good until the new crop was ripe. The dryness of the climate no doubt has a good deal to do with this, but we have still much to learn from the Orientals with regard to fruit. The soil of this mountain, as in the Bozdagh, was quite different from that of Lycia, for though the red loam appeared at the top, the sides and slopes were composed of a light schistose crumbly soil, which sucks up water like a sponge. On arriving at Cassabar I inquired for the celebrated Cassabar Melons, and was told that they are not grown in gardens but in the fields round the town, as an ordinary crop. I rode out to see the kind of soil on which they grow, and which I think must have a good deal to do with their superior excellence, as at Smyrna, only forty miles off, they do not acquire the flavour that they have at Cassabar. It is a good strong schistaceous loam, of a very light colour, and of great depth, on which Cotton and Tobacco succeed well. The Melon seed is sown in nurseries, and the plants put out in the sides of trenches in the early part of May. They are frequently irrigated in the earlier stages of their growth, and, under a burning sun, grow very rapidly. They begin to ripen in July and August, when they are exported in large quantities to Constantinople, Smyrna, and other places. This variety, the Cassabar summer Melon, must be eaten fresh; but there is another sort, the fruit of which, if cut in the autumn and hung by the stalk in a cool dry place, will keep six months or more. I have eaten them myself at the end of April, and though the flavour is not equal to that of the summer Melons, the flesh was sweet, juicy, and excellent, and the rind extremely thin. There is a third variety, a Water Melon, grown here, which is like other Water Melons, a very pleasant fruit in hot countries, but hardly worth trying in England. I have brought seed of these Melons to England, which I should be glad to send to anyone who might wish to grow them; and I have also a sample of the soil, by imitating which, I think, a considerable degree of success might be obtained. The Cassabar Summer Melon is certainly finer in flavour than any variety known in England, and would be worth a little trouble to mature well. There is an idea among the inhabitants of Cassabar that their Melons have deteriorated of late years, owing to the want of care in selecting the seed, for, whereas, formerly they were all consumed in the neighbourhood, they are now mostly sent away by rail to Smyrna, and from there by sea to Constantinople. From Cassabar I went up the plain as far as Salikly, and then turned off into the mountains, intending to visit a lake I had heard of at a considerable elevation, called the Sijekgul. It is certainly one of the most charming rides in the neighbourhood of Smyrna; and, when the line is open to Sart, will be within twelve or fifteen hours' journey of that place. A mile or two from the village of Salikly the road enters the outer spurs of the Bozdagh, which are formed of a hard whitish or red gravel, and, being worn away by the rain into sharp ridges or pinnacles, give the country a very irregular and broken appearance. For the most part these are covered with very stunted Pines and scrub; but the soil is so arid and stony, that hardly any new or interesting plants were found until I got to an elevation of about 2,000 feet. Here I passed a beautiful little village buried in fruit trees, and surrounded by fine Chestnut and Plane trees. All crops have suffered much from the drought, which is becoming very severe, and will, if rain does not fall soon, cause a famine in this part of Asia Minor, as well as in the north. Leaving the village, and winding up through the wood, the road comes on to the side of a deep narrow valley, which it skirts for some miles, leaving the river a great distance below. This valley reminded me somewhat of those in the upper part of the

* I see this is placed as a var. of *F. Lycia*, by Mr. Baker in his recently published paper on *Fritillarias*, but the plants are very distinct in appearance.

Himalayas, though vastly inferior to them in depth and grandeur, and poor, by comparison, in vegetable and animal life. Never shall I forget the marches up the Teesta river, in Sikkim, where for days the roaring of the water was so great that the voice could hardly be heard, and the track led alternately over freshly-fallen and dangerous landslips, or through the dense forest of half-tropical half-temperate vegetation, which, in the Sikkim Himalayas, are so curiously mixed together. On ascending to the higher parts of the Bozdagh, a great change was apparent in the scenery and vegetation, which became quite English in its character. The hills above 3,000 feet are only wooded in small patches, wide spaces of downy hills and rocky peaks filling up the landscape. Willows, Poplars, Oaks, Chestnuts, and Junipers were the most numerous trees here, but will not be in full leaf for another twelve or fifteen days. Here and there the mountains enclose perfectly level plains covered with rich Grass, on which large herds of horses were pasturing. These little plains or yailals are often surrounded by wooden houses, which the inhabitants of the villages below inhabit during the summer months. Very few flowers, as yet, were out; but the leaves of many bulbous plants were pushing through the soil, and gave promise of a rich harvest to the botanical collector a month or so later. Two or three species of *Crocus* were past flowering, among them the true *Crocus sativus*, the bulbs of which are larger in a wild state than those of any other species. At least two kinds of *Tulips* were common, probably *T. montana* and *T. undulatifolia*, but the bulbs were so weak and so deep in the soil that very few of them showed flower-buds. Several species of *Arabis* and *aubretia* were out; but, in the month of April, the flora of the high mountains was not what I expected. I passed the night in a miserable hut on the shores of the Sidjik Gul, a pretty little lake at about 3,500 feet elevation, surrounded by groves of fruit trees, which, no doubt, in the summer would be a charming spot; and descended the next day to Sart, the ancient Sardis, by another route. Here are some hot springs, over which baths have been erected by the villagers, and which are said to be very efficacious; if bad smells can cure diseases I certainly believe it, for the odour of the springs was most offensive, and had destroyed all vegetation, except coarse rushes, for some distance below them. I now returned to Smyrna, which I finally left on April 25th, having previously made arrangements with a Greek, who knows something of plants, to send me a supply of bulbs in the summer. If anyone wishes to know how rich and interesting the flora of Asia Minor is, let them look over Tchibatcheff's "Asie Mineure," Vol. II., where the whole of the plants are enumerated, and many described; not one-tenth of them are known in our gardens, though many would be well worth growing; and, as the country has been most imperfectly explored, many unknown treasures are sure to await the botanical traveller. In case any other person should think of visiting Asia Minor for this purpose, I should recommend the country between Adalia and Mersina on the south coast, the interior of which, as far as I am aware, has never been visited by a scientific traveller. Mountains rise within sight of the coast to an elevation of 9,000 to 10,000 feet, and, judging by the novelties Kotschy collected in the Cilician Taurus to the eastward, Karamania would offer a splendid field to an explorer. Another little known and interesting district, is that between Samsoun and Trebizond, on the north coast, though the climate is very inferior to that of Karamania. Asia Minor has been strangely neglected by English naturalists, though the antiquaries have done much there; so I hope it will not be long before a competent botanist devotes several years to this interesting and accessible country. In returning home I had to change steamers at Syra, and, in doing so, unfortunately lost a box containing a large part of my plants. Luckily I had saved a few in my vasculum, and sent away a good many to friends, but the loss was none the less very disappointing. Before leaving the island I took a walk in a different direction to the one I tried before, and by great good fortune came on a sixth species of *Fritillaria*, long past flowering, which I believe is a species peculiar to the island, *F. Ehrhardti* (Boiss.). I could only find five or six bulbs, which, however, were fat and well-ripened, and will, I hope, flower in England next

spring. Besides this, there were in flower a very small and pretty *Allium*, two or three *Ophrys* very much burnt by the sun, and an immense *Orobanch* growing in gardens to a height of 3 feet. I had, as before, no time to go far; but if, in these hurried runs over an island so well known and often visited as Syra, I was able to get several bulbous plants, quite unknown in England, it shows what might be done if a well found yacht were to cruise for three or four months in the Levant with a keen collector on board.

Leaving Syra, I arrived in two days at Corfu, where I landed, to await the boat for Brindisi. Traces of the British occupation were everywhere apparent, in the roads, the shops, the gardens, and even in the breeds of cattle, horses, and dogs. After leaving Smyrna, than which no more filthy or ill-built town exists, the contrast was most striking; and, though it is now twelve years since the English occupation ceased, the town is still far before Athens, in all but size. Having only a day-and-a-half on the island I could not see much of it, but made an excursion to the top of a mountain about eight miles from the town. Potatoes are largely grown in Corfu, as well as Vines, Flax, and Corn, but Olives constitute the principle crop of the island. I never saw Olive trees finer or more numerous, the whole country being more or less covered with them. Under their shade grew Bracken abundantly, but of herbaceous plants I saw very few worth notice. Several pretty Orchids were common, and on the top of the mountain I found the bulbs of an autumn *Crocus*, a small *Colchicum*, and a few other plants. I was caught in a heavy shower of wind and rain, for the first time since March 21st, the weather having been splendid during the whole of my tour, and hot in the middle of the day. Returning to the town of Corfu, I went to see the gardens originally laid out by the Lord High Commissioner, round his villa on a hill a mile from the town, which, since our evacuation of the island, have been kept up by the King of Greece. They are well worth a visit, being full of fine and interesting trees and shrubs. Most of the Olive trees having been left standing, the grounds are very wild and natural, but the long Grass which covered much of them looked rank and untidy. I found the second gardener, Joseph Buzzai, a very intelligent man and was shown by him all over the place. Loquats (*Eriobotrya japonica*), the fruit of which was fast ripening, Oranges, and Lemons, of many varieties, were the most numerous trees, but many Conifers have been planted of late years. A splendid Judas tree, *Cercis siliquastrum*, was not less than 25 feet high, by 35 in diameter, well-grown, and covered with bloom. *Fraxinus ornus* was now showing its graceful white flowers, which should be better known in England than they are. The twigs of this tree (as Buzzai pointed out to me) when broken and put into water, give it a bluish tinge. Several species of *Musa* were growing, though not thriving in the open air; but *Paulownia grandis* and *Cosmophyllum calalioides* had been killed by the winter's frost. There was a fine young tree of *Cheirontoma siliqua*, 12 feet high, only five years old, from seed, besides many other curious things, such as *Lycoperdium peltatum*, *Scinos pseudopiper*, *Percunia dioica*, and others which are little known in this country. *Acacia tomentosa*, a very pretty sort, covered with light brown hairs, was grafted on *Robinia* and doing well, as were also *Photinia arbutifolia*, *Pittosporum majalis*, and *Justicia arborea*. *Amaryllis longifolia* was abundantly planted and apparently quite indifferent to cold, but it is not a plant I should recommend for small gardens. Whilst wandering through the glades I came on a natural garden of terrestrial Orchids, which, sheltered to a certain extent by long Grass, were growing abundantly and with unusual luxuriance. *Serapias lingua* and *longipetala*, *Orchis laxiflora* (3 feet high), *Ophrys* *lutea*, *arachnites*, and another beautiful species resembling *ferrum equinum*, with from eight to twelve flowers on a stem, besides one or two other varieties, were crowded as thickly as possible over several square yards of ground. The soil was a heavy and deep loam, much baked by the sun, notwithstanding which, I never saw Orchids growing so strong anywhere else. I got up a good stock of tubers with some trouble, and hope to grow them well in pots, as I am afraid they will not be hardy in England.

On my return home through Italy, I saw, at the Botanic Gar-

dens at Genoa, a fine lot of the native Orchids, planted in a mass of Sphagnum on a hot paved terrace; and, apparently growing well; among them, was that rare and curious plant *Isias triloba*, supposed to be a hybrid between *Scirpias lingua* and *Orchis longicornis*. It has only been found in the Maritime Alps at a low elevation, and I believe always in the neighbourhood of its supposed parents. I had not time to stay for the Florence exhibition, which was to take place the week after, but saw quite enough of Italy and the Italian flora to make me wish to go again. Hoping that the result of my rambles in the Levant may be to induce others to visit the same country, I have written this slight sketch of what I saw, and should be happy to give fuller information to anyone proposing a similar tour. H. J. ELWES.

Wild Flowers at Galashiels.—One of the most interesting features of an exhibition which was lately held here was the bouquets of wild flowers shown by children. About 300 of such bouquets were exhibited; some were of a rough-and-ready make, but the greater number of them were neatly and tastefully put together. The most interesting were composed of as many as forty varieties of flowers. The prettiest were those with an under ground-work of flowers dotted over with the heads of many fine and rare Grasses. Fifty prizes were offered, principally in the shape of articles of ornament and use. These were contributed by ladies and others interested in such matters in the neighbourhood. In the case of so many prizes one or two exhibitors do not carry off the whole, and more interest is thus created than if they were fewer. No entry money is required, and each little exhibitor gets a penny, a system which is extending through all the border counties; and the advancement each season, both in the number of entries and the manner in which the bouquets are made up, is highly gratifying, and denotes how thoroughly such encouragement is appreciated. Even at metropolitan exhibitions there need be no want of wild flowers, for woods and fields furnish abundance of them, and those who have not access to these might get enough and to spare growing by the road sides and on public commons. The display at Galashiels would have done honour to even our best metropolitan shows, and I am certain that the simple beauty of the flowers would gratify all, more especially those who have hitherto been satisfied with what may be termed show bouquets.—J. MURK, *Clonelfords*.

Foxgloves.—Everyone who has seen a hedgerow in summer is familiar with the Foxglove, which is one of the most plentiful of wild flowers. It grows on the very summit of high hills, in recesses, in deep ravines, amongst heaps of stones, about old ruins, amid dense masses of other kinds of vegetation, and often under the shade of large trees. It has been long banished from our gardens, but, I fully anticipate, that when a taste for beautiful and altogether hardy flowers has been re-developed, the Foxglove, and others of its class, will again adorn many quiet spots and corners, which, at present, are nearly void of interest. Foxgloves remain in flower from May until August; the blooms at the bottom of the spike opening before those at the tip are well-formed, and the flowers vary in size according to the quality of the soil in which the plants grow. *Digitalis lutea* and *D. grandiflora* produce fine yellow flowers; *D. gloxiniflora* and *D. maculata* are beautifully spotted; in height they vary from 2 to 1 feet. The genus is not rich in varieties, but, doubtless, many new and superior kinds would soon be forthcoming, were there any demand for them. Those, however, which have just been named are equal in merit to *Pentstemons*; they are certainly as pretty as *Pentstemons*, and capable of being made quite as useful. A pure white one grows wild here, which, according to my way of thinking, is well worth attention. In habit, it seems adapted for pot culture, and a fine pot plant it would make; it only grows about 18 inches high and forms a dense mass of dark green leaves and many branching spikes of white flowers; I have occasionally found it in other places in Scotland, but it is by no means common.—J. MURK, *Clonelfords*.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Fuchsia procumbens.—I have just seen flowers and leaves of this pretty creeping New Zealand Fuchsia, and think that it well deserves culture as a basket or window plant or in other positions in which it can be brought near the eye. It has a gracefully drooping habit, bright green leaves, and metallic, purple, yellow, and green-tinted flowers without petals; the filaments are of a vivid crimson colour, and contrast well with the yellow tube.—B.

Tobacco (*Nicotiana Tabacum*).—We have received from Mr. Iverson specimens of two varieties of Tobacco, both of which are now finely in flower in the Regent's Park. The blossoms of the one are deep carmine; those of the other rosy-pink, and both have large and fine foliage, illustrating in a remarkable manner the good effects which the late warm weather has had on the growth of these plants. In summers like this, indeed, Tobacco is worth growing for the beauty of its flowers as well as for that of its foliage.

IN THE TIME OF YUCCAS.

MUCH might be written, and that to good purpose, on the stately effects to be obtained by the judicious planting of Yuccas of different kinds in garden scenery. It is impossible to overlook the beauty of Yuccas, even when planted singly or in formal lines; but, if arranged in bold groups and masses, they are unsurpassed as flowering and foliage plants for outdoor decoration. Just now, and for the next two months, Yuccas will be in flower, and their great panicles of pearly-white bell-shaped blossoms contrast so well with bright green Conifers and low-growing shrubs of less distinct contour, that all through the summer and autumn it is possible to form charming pictures by massing them either on the margins of shrubberies or in sheltered nooks on the lawn and pleasure grounds. This plant is simply invaluable if properly used in forming picturesque groups and clumps instead of being, as is too often the case, dotted indiscriminately here and there on turf in unmeaning regularity. It has been said that the Hollyhock is the only decorative flowering plant of any importance to the landscape gardener. Yuccas are even more stately however, and, moreover, they are permanent in character, being quite as ornamental in winter as in summer. They succeed nearly equally well in any soil, but a deep rich well drained loam is preferable, and they make finer specimens, if sheltered from rough cold winds, than they would do if more exposed. The flowers of all the species (and these are more numerous than many imagine) closely resemble each other, being mostly of ivory-like whiteness within, the backs of the thick wax-like segments being more or less tinted with purple. One of the most conspicuous in this way is *N. tortulata*, or, as it is sometimes called, *N. Ellacomiana*. This bears immense panicles of large flowers, the backs of which are of a deep bronzy-crimson colour. Where all the species are good it is a waste of time to individualise. Much may be made of Yuccas by associating them in well-arranged masses along with other distinct and gracefully habited plants—such as the Pampas Grass, *Arundo conspicua*, hardy Bamboos, Dwarf Fan Palms, and a score of other valuable decorative plants too seldom seen in our gardens. Our engraving shows how a shrubbery recess may be made a charming picture by the use of Yuccas alone; and it is in positions such as these that the flowers show to the best advantage. The kinds here shown are *Y. filamentosa*, on the left, a kind which bears rather lax but graceful spikes of flowers. The central specimen is *Y. aloiolia*, a form generally met with in cool conservatories, although perfectly hardy in sheltered positions in Devon and Cornwall, and it is rather a curious fact that the variegated form of this plant is found by Mr. Ellacombe to resist cold better than the normal kind. Both, however, make noble plants. The right-hand figure represents the common Adam's Needle (*Y. gloriosa*), one of the most robust of all the species; and associated with it is the free and vigorous *Y. recurva*, the most common in English gardens. These last rarely fail to flower every year. Many kinds of Yucca are now flowering at Sawbridgeworth, planted on a slightly elevated bank, where they form an irregular line thirty or forty yards in length. In the Coombe Wood Nursery too, in the Regent's Park, and in Messrs. Osborn's nurseries at Fulham, are noble isolated specimens and clumps of Yuccas, associated with choice Conifers, evergreen shrubs, and other decorative plants; while those who have been fortunate enough to visit Mr. Ellacombe's garden at Bittou, will not readily forget the great masses of *Y. recurva*, which jut out on the fresh mossy turf, backed by choice Conifers and noble forest trees. Among the many advantages possessed by Yuccas over other hardy evergreen plants is the vigorous growth they make in town gardens where many other plants would fail. We have on former occasions alluded to the adaptability of Yuccas for balcony decoration, for which, perhaps, no other class of plants, except Agaves, is so well suited. Yuccas have been grown in English gardens for nearly three hundred years, and yet they are far from being plentiful. Since the above was written, we have seen a grand mass of these plants on the over-hanging banks of a small lake, where, associated with dark-leaved Yews, bright green Weeping Willows, and similar waterside vegetation, their effect was excellent.

GROUP OF YUCCAS IN THE BLOOMING SEASON.

THE FRUIT GARDEN.

CRANBERRY CULTURE.

By E. W. CRANE

THE Cranberry is found growing wild in many parts of the world. It belongs to the Heath family, and the genus *Vaccinium*. The European Cranberry (*V. oxycoccos*), a small mottled berry, grows in some parts of England, Scotland, Germany, and Sweden, and on the steppes of Russia; the same species is found in different portions of the United States, but we do not hear that it has been successfully cultivated in either country. The American Cranberry (*Vaccinium macrocarpum*), is found in most or all of the States, from Maine to the Carolinas, in Oregon and Washington territories at the north-west, in the British possessions, and even in Alaska. It is much larger than the European, and of greatly superior flavour,—also generally of a darker and brighter colour when mature; while growing, it is of a light green, which changes in ripening to a light or dark red, or crimson, and sometimes to a mottled colour, the berry being from one-fourth to 1 inch or more in diameter. It blossoms in June and the fruit ripens in September and October. The runners of the plants are from 1 to 8 or more feet in length, and with oblong leaves. It may properly be called an evergreen, though the leaves turn to a brownish hue during the fall, especially when the vines have been cultivated, and set in sand. The American Cranberry is divided, by growers and writers on this subject, into three leading varieties:—1. The Bell Cranberry, so called because of its fancied resemblance in shape to a bell.—2. The Bugle Cranberry, somewhat resembles a bugle head, is elongated, and approaches an oval in shape.—3. The Cherry Cranberry, is so called from its similarity in size, shape, and colour to the Cherry. These varieties too, run together, and produce intermediate ones.

The plants also differ; some are of a shorter growth than others, and apparently produce more fruit and less growth of plant. These are of course to be preferred, but, until recently, little attention has been given to this subject, it being popularly supposed that the wild nature of the Cranberry could not be successfully altered to any great extent, for which there has been some foundation in fact, but experiments are now in progress, which will doubtless add to our knowledge on this point, as well as others of interest in regard to cultivating the fruit. No other species of which we know, is so successfully cultivated anywhere, as is this, in the United States,—between 38° and 45° north latitude—though it is said that this limit may be extended several degrees southward in the Alleghanian ranges; and also several northward, on our western coast, on account of the peculiar influence of the ocean currents upon the climate. A medium between these latitudes is preferable, though there are but comparatively few localities where all the requisites of soil, sand, water, and climate are to be found; and less land is well adapted to their growth than to almost any other fruit. These requisites, however, are believed, by careful observers, to exist in greater perfection in Southern New Jersey, than in any other state, or part of the world. The first attempts to cultivate this fruit, of which we have any knowledge, were made by Captain Henry Hall, of Dennis, Mass., on Cape Cod, in the year 1812, sixty-two years ago. I have recently learned, through his family, that the original plants last year yielded a fair crop, as they have hardly ever failed to do since they first came into bearing. His townsmen, for a while, ridiculed his efforts, but seeing his success soon began to experiment themselves, and with good results. Many difficulties, however, were encountered, and it was nearly forty years before the Cranberry was generally cultivated on the Cape, which locality for a time almost entirely supplied our markets. B. F. Small, Esq., now of Orange in this State, related to me some time since, that he remembered that when his father Captain Z. H. Small, of Harwich, Mass., one of the earliest and most successful cultivators, after several years' efforts, succeeded in getting a crop of 100 barrels, it was thought that he had indeed overstocked the market, and it was with some little difficulty that he disposed of the fruit at low prices, much lower than growers have generally since received, notwithstanding that the production has increased a hundred-fold. The best locations for the growth of the Cranberry are peat bottoms, with adjoining banks of pure sand (for covering the plantation before the plants are set), and so situated that they can be completely flowed by living streams during the winter, as well as thoroughly drained at other seasons of the year. Many growers have a decided preference for Cedar swamps, and (although other bottoms are sometimes perhaps equally as good) they are considered, when favourably located, as rather the surest, though more expensive to work. Cranberries grow well, also, on good "savanna," which is a mixture of peat and sand—but not so abundantly, nor do they last so long as on peat bottoms. The recommendation of the late Prof. Agassiz, to avoid the drift formation, or that portion of it consisting of rocks not in

place, gravel, clay loam, &c., has been found correct in practice. Many experiments have been made on this kind of land, but nearly all of them have proved failures. Dr. Cook, our State Geologist, states, that even muddy water running over the vines is extremely detrimental, if not fatal, to their growth. In preparing a plantation the surface must first be cleared of the wood, timber, or brush; then it must be "turfed,"—that is the surface soil and roots must be taken off with a hoe made for that purpose; the next step is to ditch it, by clearing out the main water-course, and digging side drains running into it—generally in deep, bottom lands, about one and a half or two rods apart, but the distance should be varied in accordance with the nature of the ground. The floats removed in turfing are used for levelling up low places where needed, so that the surface may be slightly rounded between the side drains; they are also used for building the dam, which is constructed with two walls of the floats, filled in with sand, a ditch having first been cut between them to the sand beneath; the solid filling makes it water-tight.

After turfing and ditching, peat bottoms must be sanded to the depth of from 1 to 6 inches with pure sand, without mixture of clay or loam, and it should be taken at a sufficient depth below the surface to avoid seeds. The silex imparted to the plant from the sand materially promotes its productiveness, and also tends to prevent the growth of weeds. Many experiments have been made to ascertain the proper depth to which the sand should be applied; where little or none is used, the vines grow long and slender, and do not fruit so well as when sanded. While some have thought 2 inches sufficient, others have tried a thickness of 12 or more, and with good results; though with this amount the plants make a slower growth on account of the length of time required for the rootlets to reach the peat beneath, from which they draw their support. Most cultivators, however, have concluded that the above depth (from 1 to 6 inches) is about right for bottom lands when prepared, though it should be varied somewhat according to the nature of the soil (deep muck requiring most), and that re-sanding every few years with a layer of from 1 to 2 inches, is preferable to using a much larger quantity at first. The sand is generally obtained in the banks adjoining the edges of the swamps, from which it is brought, if a short distance, in wheelbarrows, and if a long one, by means of a dump car and portable track. In some localities, however, it can be more easily obtained by sinking pits to the layer beneath the peat—when the latter is not too deep—from which it is thrown up and spread over the surface. The pits are filled up with floats, &c., allowed to settle, and then covered with sand. After sanding, the vines are set in rows about 20 inches apart, and but a moderate quantity of vine should be used for each hill. This is the usual method, though the distance is often varied either way. Mr. Gowdy has, from recent experiments, concluded that the vine should not be set over a foot apart, and that the additional cost of the vines, &c., will be more than paid by earlier and larger crops, as well as by the matting of the vines in much less than the usual time—which keeps down other vegetation, and saves labour and expense in cleaning.

Plantations should be well flowed with water from December until May. The water fertilises the vines, protects them from frost, and is the only reliable remedy known for the vine worm, which is one of our worst enemies. It is thought that the warmth of the water, when held on the vines to the 10th or 15th of May, destroys the eggs deposited on the leaves of the previous year; hence the advantage not only of late, but thorough flowing, as the portions not flowed often constitute a hatching ground for the worms, from which they spread to the adjoining vines, though it has been noticed that they apparently prefer not to go much beyond the water line, if they can find sufficient vines that have not been flowed. It is best to keep the ground free from weeds and Grass for two or three years after the vines are set; the ditches should also be cleaned of the sand, &c., which frequently runs into them. This costs usually from 10 to 20 dollars a year per acre, but if carefully done on well located and properly prepared land, the expense is afterwards, as a general thing, comparatively slight, as the vines should by that time have possession of the ground, and prevent, to a great extent, the growth of other vegetation—and with an occasional re-sanding to the depth of from 1 to 2 inches, which produces a new growth, the plantation will last a great number of years—in fact, indefinitely—for, as before mentioned, the original vines set on Cape Cod more than sixty years ago, last fall produced a fair crop. Some growers, especially on the "Cape," occasionally mow off the old vines in order to obtain a new and vigorous growth, and savanna plantations have been renewed, by carefully ploughing them up, in which case, the vines come up between the furrows, and spread over the whole surface. When either of the last mentioned methods are practised, there is generally a loss of one or two crops, which there need not be by the first one, if the work has not been

too long delayed, so that there is a large growth of old wood. It may be said, however, in favour of mowing, that where the Vines are good, and there is a demand for them for setting, they will often sell for as much as a crop of fruit, or perhaps more. The berries ripen in September and October. The "picking season" generally commences about the 10th or 15th of September, lasts from four to six weeks, and furnishes employment to thousands of women, girls, boys, and sometimes men. A good plantation at this season, with its rich load of fruit, presents a beautiful as well as a lively scene. Good pickers will generally pick about three bushels per day, though some have picked as high as four or five, and even more. Many of the younger ones, however, will pick but one bushel, so that in a force of fifty or one hundred pickers they generally average, in good work, about two bushels per day. The berries are generally emptied from the pickers' baskets or boxes into crates or barrels, in which they are carted to the place where stored. For storing, a dry well ventilated cellar is generally preferred, and crates are better than barrels, because more conveniently filled, and if strips are placed between them, as they always should be, a good opportunity is given for the circulation of air, and it is thought that they will keep better. The berries are then shipped principally to the great Cranberry markets of New York and Philadelphia, many of them without re-sorting, though the most careful growers now re-sort and screen their fruit if kept long after picking, before shipment; it should also be carefully looked over when picked, and the packages well filled just before shipping, both to give satisfactory measure, and because they carry better in full packages. The standard packages are barrel, bushel, and peck. The barrel adopted is the same as the standard barrel of the Cape Cod Cranberry Growers' Association, which secures uniformity when their fruit comes into competition with ours. It is made of 28½ inch staves, so jointed as to give a bilge of 7½ inches; heads 16½ inches in diameter, and set in staves so as to leave the inside measurement 25½ inches. The finished barrel is about 28½ inches in height, and contains three bushels rounded measure. The bushel crate measures 8½ inches by 12 inches by 22 inches, inside, exclusive of the middle partition, contains 2.211 cubic inches, and holds one bushel, rounded measure—just one-third as much as the barrel. The peck crate, or box, measures, 6 inches by 8½ inches by 11 inches, contains 552½ cubic inches, and has one-quarter the capacity of the bushel box. The "round" in all consists of 3½ quarts per bushel, in addition to "struck" measure. The packages hold just the quantities mentioned when well filled, as packages of Cranberries should always be for shipping.

But little fruit can be expected until the plants are three or four years of age, when they should begin to bear paying crops, which should increase yearly for two or three years, when they are said to be of full bearing age, and with the attentions mentioned, on well-selected and properly prepared land, should last indefinitely. An average of 100 bushels per acre for a plantation, though not an immense yield, is considered a very good one. Many have exceeded it, but many more have fallen below; and, probably, an average crop for all classes of land in a good season would not exceed 50 bushels to 75 bushels per acre. Probably, the best crop on record for 1 acre, was that of 1 acre of the celebrated Oxyecocos plantation of Mr. N. H. Bishop, of Manahawkin, in 1872, from which was sold 423 bushels for 1,809 dollars gross, though parts of acres have yielded at higher rates than the above. A few rods of one of our own plantations yielded, during the past season, at the rate of over 700 bushels per acre, and larger rates still are reported for 1 or 2 rods; but these, of course, are exceptional cases. Single crops, however, have often paid fifty per cent., and even more, on the original cost. Some, however, think that such profits will not again be realised, and it cannot be denied that many have lost money in the business. Some plantations have proved failures, and others, doubtless, will do so, though most of them occur on poorly selected land, on which the work has perhaps been imperfectly done at first and afterwards neglected. No ground should be prepared for Cranberries unless it can be completely flowed, and those engaging in the business should either have a practical knowledge of it themselves, and give it their personal attention, or first secure the services of some one who has—for the capital invested is frequently lost either through ignorance or carelessness.

[The above is an abstract from an admirable paper in "The Report of the New Jersey State Agricultural Society," which tells the interesting history of Cranberry culture in that State, so well suited to its culture in many parts. The fruit is an excellent one which could be cultivated on many of our own peaty lands. The following are the best tested modes of cooking and preserving Cranberries. It may be noted that they are extensively preserved in tins.]

Keeping Cranberries.—Select sound berries, and store in crates or shallow bins, or spread on floors, not more than 8 or 10 inches in depth, where the direct rays of the sun cannot affect them. A dry,

well-ventilated room or cellar is best; damp cellars and hot rooms should be avoided, and the temperature kept as even as possible. In this way the fruit will keep a long time.

General Remarks on Cooking.—As a preliminary to all receipts, it may be remarked, to save repetition, that very soft berries should first be removed, and those remaining thoroughly washed, after which they should be placed in scalding water for about two minutes, and then taken out; this removes a portion of the acidity, and a little less sugar will be required. Be particular to use fine white sugar (granulated is best), and not too much water: the proportions given of each, it is thought, will suit the majority of tastes, but when found otherwise, the quantities can be made larger or smaller, though in using a great deal more sugar the distinctive Cranberry flavour will be partially lost; some may prefer one pound of sugar where the amount specified is three-quarters, but probably others will be better pleased (if changed at all), to make it smaller, perhaps one-half a pound, especially for dinner sauce, which makes the preparations at least very palatable, and has the advantage of economy; but when desired to keep a long time, without canning or sealing, a larger quantity should be used. On account of the acidity of the fruit it is preferable, though not positively necessary, to use porcelain lined cooking utensils.

Receipts.

Cranberry sauce is the great American Cranberry dish, and the most popular one for general use, either for dinner or tea. As a relish for game, poultry, and meats of all kinds, it is unequalled. To every pound of fruit add three-quarters of a pound of sugar and half-a-pint of water. Stew them together over a moderate but steady fire. be careful to cover and not to stir the fruit, but occasionally shake the vessel, or remove to a gentler heat, if in danger of sticking or burning. Attention to these particulars will ensure the berries retaining, to a considerable extent, their shape, which is so desirable, and adds greatly to their appearance on the table. Boil from five to seven minutes, when they should be removed from the fire, turned into a dish, and set aside to cool. If to keep, they can be put at once in air-tight jars. This is preferred by many to strained sauce, but where that is desired, one and a half pounds of fruit should be stewed in one pint of water for ten to twelve minutes, until quite soft, then strained through a colander or fine wire sieve, and three-quarters of a pound of sugar thoroughly stirred into the pulp thus obtained, when, after cooling, it is ready for use.

Pies and Tarts may be made from either of the above preparations, no upper crust being necessary, except, if fancied, in the shape of narrow-crossed strips.

Covered Cranberry Pies (which were known, are generally considered superior to those above-mentioned), may be made as follows: make an upper as well as an under crust, completely encasing the berries, which should be put in raw, with a quantity of water equal to about half their bulk, and sugar in the proportion of three-quarters of a pound to one pound of fruit, care being taken to sprinkle it well around the edge; also if desired, sift a little wheat flour over them to thicken the pulp. Bake same as an Apple pie, and eat hot.

Cranberry Jelly.—To each pound of fruit add half-a-pint of water; after the berries become very soft by cooking, strain through a bag, and add one pound of sugar for every pint of juice. Boil and skim until jelly is produced, which can be tested by occasionally dropping a little in cold water; when it falls to the bottom without mingling with the water, the jelly is done, and should be taken from the fire. Pour while warm into glasses or moulds (having first rinsed them with cold water to prevent sticking); and set in a cool room to harden. Another, and simpler method, which produces beautiful jelly, and is preferred by many (though it will not keep a long time) is to add the sugar to the juice without further boiling, by sprinkling and thoroughly stirring it in. If the above quantity of sugar should not make it quite stiff enough, add a little more, and after pouring out, let it stand several hours to harden.

Preserved Cranberries.—Dissolve three-quarters of a pound of sugar in half-a-pint of water, and after bringing to a boil, add one pound of light or cherry-coloured berries (not allowing them to be over 2 inches in depth on the bottom of the kettle, which should be covered), and cook until they begin to break, when remove them with a strainer to a deep jar or dish, allowing the syrup to remain three or four minutes longer, and then pour it over the berries, which can be set aside for immediate use, or sealed up in glass jars as desired.

Sweet Pickled Cranberries.—Prepare the large berries by punching a few holes in each with a large needle; this will allow the pickle to enter the fruit. To a pound of berries add half a pound of sugar dissolved in a quarter of a pint of vinegar. Cover the

vessel, and cook from eight to ten minutes (if boiled too long they will not remain firm), when remove them from the pickle, and continue boiling it until it thickens; then pour it over the berries, adding spices to your taste.

THE ARBORETUM.

PEACH-LEAVED CHERRY.

(*CERASUS PERSICIFOLIA*.)

THIS shrub, the *Prunus Pennsylvanica* of Aiton, is a native of North America, probably of Pennsylvania, whence it is said to have been introduced into France by Michaux. It forms a very handsome hardy shrub, with narrow lance-shaped leaves, borne on reddish leaf-stalks, of a lively shining green colour, sometimes marbled with yellow. The flowers, which begin to appear about the middle of April, are white with yellow anthers, and very numerous, on long thin stalks, and are arranged in umbel-like clusters. The fruit, which are about

Cerasus persicifolia.

the size of Peas, are also very abundantly produced; and, being of a glistening red colour, give the tree a highly ornamental appearance, hardly inferior to that which it exhibits when in flower. *C. persicifolia* appears to be closely related to *Prunus reclinata* (Bosc.). It is easily multiplied by grafting on the *Cerasus Mahaleb*, on which it succeeds to perfection. This shrub, if more widely known, would, no doubt, take a prominent place among our ornamental flowering shrubs.

W. M.

MOCK ORANGES AND DEUTZIAS.

AMONG Mock Oranges a large number of handsome species are natives of Europe, Asia, and America, generally hardy, and well adapted to the soils and climate of Britain. All the sorts have beautiful white flowers, in some cases delightfully fragrant, and both in general appearance and perfume resembling those of the Orange tree. These fine plants were much better known and more extensively cultivated by the gardeners of the last generation than they are now; but notwithstanding the numerous grand accessions to hardy shrubs of late years, they have many qualities which still entitle them to the attention of the decorative planter; their free vigorous growth, in the poorest soils, and their adaptability to either sunny or shady situations, combined with their attractive foliage and showy blossoms,

render them invaluable wherever robust, bushy, and, at the same time, really handsome shrubs are to be desired. Of the species and varieties of Mock Orange or *Philadelphus* in cultivation, we recommend the following as specially distinct and interesting:—

P. coronarius (the Garland Mock Orange).—This species is said to have been introduced into British gardens so long ago as 1596, and thus may fairly be ranked among "old-fashioned" plants. It is, however, handsome enough to be associated with the finest of the new shrubs of robust growth, producing the happiest effects when planted on the margins of plantations of trees, woodland drives, or large shrubberies; while no plant thrives better amid the dust and smoke of towns. It forms an abundantly branched, densely foliaged, broad bush of from 10 to 15 feet in height, bearing its bunches of creamy-white orange-scented blossoms in June, and generally in great profusion. The leaves are ovate, acuminate, and serrated, of a deep green colour above, and paler beneath. It is hardy enough for the most exposed situations; and as regards soils, prefers such as are light and porous.

The undernoted varieties are no less hardy and interesting than the parent, and as they are distinct and ornamental, should be extensively cultivated; *Flora pleno* has double flowers; *Variegatus*, with its leaves margined with a prominent white variegation which they retain during the season, and which, apart altogether from its showy flowers, gives the plant a charming effect; *Nanus* is a neat-growing miniature form, rarely rising above 2 feet from the ground, and useful for rockeries, front rows of shrubberies, or any arrangement of compact dwarf plants.

P. grandiflorus (the Large-flowered Mock Orange), is a North American species, and has been in cultivation since the beginning of this century. It is a very hardy vigorous shrub, growing freely in most situations and soils if dry and porous, having a thickly-branched broad-spreading habit of growth, and rarely higher than about 15 feet. The leaves are ovate, with a long acuminate tip, and prominently dentated. The snow-white flowers are large and showy, but scentless, and are in perfection in June or July. The variety called *speciosissimus*, has larger flowers, and is said to produce them in greater abundance than the species. Both are very ornamental, and may be used with great advantage for similar purposes to those for which we have recommended *coronarius*.

P. verrucosus (the Warted-leaved Mock Orange) is another North American species introduced about 1800. It is a hardy and a most vigorous-growing shrub like most of its congeners, thriving best in dry light soils, and forming a close bush of about 15 feet high. The leaves are elliptic, acuminate, light green above, slightly pubescent and curiously warted on the mid-rib and veins below. The flowers, which are produced in most seasons very abundantly in racemes, are pure white, expanding in May or June. It is a most beautiful and distinct-looking flowering shrub, very showy when in bloom.

P. Gordonianus (Gordon's Mock Orange).—This species is indigenous to the north-west coast of North America particularly in the vicinity of the Columbia river, where it occurs in woods covering vast tracts as undergrowth. It was first sent to this country in 1823, is of free growth in any kind of garden soil, and hardy enough for any situation. This fine species, though wanting the sweet fragrance so pleasing in some of the others, is most desirable, and should never be overlooked in making a selection of strong-growing flowering shrubs. The habit of growth is broad and bushy, the branches long, and so slender in proportion to their length, that they have a somewhat drooping appearance. The leaves are ovate, acute, and of a beautiful warm green colour. The large white flowers, which in genial seasons are produced in such abundance that they almost cover the foliage, generally come out in July.

P. speciosus (the Showy Mock Orange), also from North America, and introduced about 1800, is another very hardy, free-growing, and free-flowering species, with a broad, bushy, densely-branched habit of growth, of from 12 to 15 feet in height. The leaves, which thickly clothe the long slender branches, are ovate, sharply acuminate, prominently serrated, of a deep green on the upper surface, and pubescent below. The flowers are pure white, and are generally in perfection early in June. When in bloom it has an admirable effect, and, having a graceful and distinct appearance, it is eminently worthy of admission to any shrubbery. It should always be planted in an open sunny situation.

Deutzia.

This genus, so named by Thunberg in compliment to the accomplished Dutch naturalist John Deutz, though quite distinct in general appearance, is botanically nearly allied to *Philadelphus*. As yet there is a very limited number of species and varieties in cultivation, and these, though natives of India and Japan, are either quite hardy in our climate, or sufficiently so to withstand the rigours of an

ordinary winter in a sheltered situation. All the sorts are deciduous moderate-sized shrubs, and remarkable for their showy flowers, which, in favourable circumstances, they produce in great abundance. From the facility with which they may be forced into bloom, these beautiful plants are extensively used, and form an important feature in the winter and early spring decoration of greenhouses and conservatories.

D. scabra (the Rough-leaved Deutzia).—This species is indigenous to mountainous districts in Japan, and was first introduced in 1832. In that country it is a favourite ornamental shrub, and is frequently seen not only in gardens but as a hedge plant. In our shrubberies it forms a strong-growing broad bush of about 6 feet in height. The leaves are ovate, acuminate, serrated, and covered with minute, stellate, silicious hairs; which, we may notice, are singularly interesting objects for examination by the microscope. The starry snow-white flowers are produced in compound panicles, in May or June, and when in perfection have a splendid effect. It requires a light, well-drained soil, and a sheltered situation—open, however, to the full sunshine, that it may be enabled to ripen its growths thoroughly before the winter sets in.

D. gracilis (the Slender Deutzia).—This superb little shrub is also a native of Japan, and was introduced about 1835. It is of a dwarf bushy habit of growth, rarely seen higher than about 3 feet. The branches are numerous, very slender, and abundantly clothed with smooth, lanceolate, dentated leaves of a bright green colour. The pure white flowers are produced in axillary panicles, and in ordinary seasons are in perfection in May. Though quite hardy if planted in a light dry soil and in a sheltered situation, and though naturally the most profuse-flowering of the genus, it is only in exceptionally favourable seasons that its full beauty is developed in the open air in this country. It is, therefore, chiefly as a greenhouse plant or for forcing that it is now so extensively grown; and it is one of the best known and most popular of winter and early spring conservatory flowering shrubs. For this purpose it is usually kept in pots, and plunged in a sunny border out-of-doors during the summer months, freely watered during the growing season, the supply being gradually diminished as the shoots begin to ripen, and the leaves show signs of decay. On the approach of winter the plants are stored under glass, to protect them from frost, and transferred into the forcing-house from time to time, thus securing a succession of bloom, if desired, from January till May. As they are easily excited into growth, a gentle heat is all that is either necessary or desirable, unless, indeed, they are required very early, in which case it is best to put them into a warm temperature as soon as possible after the leaves fall. While growing freely, and immediately before the flowers expand, a dose of weak liquid manure will be found very beneficial in assisting the free development of both foliage and flowers. For pot-culture a compost of three parts fresh light loam and one part well-rotted leaf-mould, with a liberal allowance of sharp sand, is found to suit admirably. A well-managed specimen of this lovely plant, with its fresh, warm, green leaves and graceful blossoms, has a charming effect in winter, and is not only invaluable for decoration, but supplies the most beautiful sprigs for hand-bouquets, surpassing in everything but fragrance the much-admired Orange-blossom, for which they might easily be mistaken.

D. crenata plena (the Crenulated-leaved Deutzia).—This magnificent, free-growing, hardy shrub is a native of Japan, and was sent home by Mr. Fortune in 1860. It has a handsome, open, slender-branched habit of growth, and is quite distinct, both in foliage and flowers, from any of the other species. The leaves are ovate, acute, crenulated, and of a light-green colour; the flowers are produced in large terminal racemes, double white, and the petals punctately tinged on the outer surface with deep rose. Though requiring a sheltered situation, it is quite hardy, and, in favourable circumstances, flowers freely in the open air. Like *gracilis*, it is an admirable forcing shrub, and when treated in a similar manner to that species, gives a grand feature to the conservatory during the winter months.—*The Gardener*.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Abies Gordoni.—The *A. Gordoni* of Carrière, to which allusion is made in your last number (p. 73), is the *Picea grandis* found on Vancouver's Island. It differs slightly from the *P. grandis* of Douglas, inasmuch as it has somewhat larger leaves, but in other respects it is the same.—*GEORGE GORDON*.

The Catalpa as a London Shade Tree.—The Catalpa in the South Lambeth Road, of which I think there was a notice in an early number of *THE GARDEN*, was a beautiful sight when I passed it the other day. It was covered with handsome panicles of blossom, and was well worth going some distance to see.—*F. H.*

Branch-shedding in Trees.—It is a character of some trees, of the Elm in particular, to drop large branches during the hot months, without any external warming beyond, perhaps, a preliminary crack or two. The branches that thus suddenly snap are as verdurous as any of the others; and there seems to be no other defence than to avoid "the Elm tree's shade" as much as possible.

SQUILLS (SCILLA).

This family is now becoming of so much importance in our gardens in spring, that a full account of the known species from a botanical point of view, can hardly fail to be suggestive to the lover of hardy bulbs, and useful as a reference in the naming of species. *Scilla* is a somewhat extensive genus of bulbous plants, containing seventy-two species, mostly of low stature, with linear or thong-like, lance-shaped, radical leaves, usually appearing together with the flowers. Flowers, numerous, small, bell-shaped or tubular, in racemes, of a deep sky-blue or rosy-purple colour, seldom greenish or whitish; pedicels, not articulated; bracts, linear or deltoid, solitary or in pairs, seldom obsolete. A few species (two of which, *S. bifolia* and *S. sibirica*, are of rare beauty) are cultivated in our gardens, and thrive to perfection in a compost of rich fibrous loam and sand.

Key to the Species.

Sub-genus 1. Eusquilla.—*Segments of the perianth (or flower) spreading from the base; filaments, in a single series, springing from the lowest part of the base of the segments.*

- | | |
|--|-----------------------------|
| Ovules, solitary in the cell of the ovarium (<i>Barnardia</i> , Lindl.); leaves, two or three; capsule, turbinate; leaves, somewhat hard, 2 or 3 lines in diameter | 1. <i>chinaensis</i> |
| Leaves, herbaceous-fleshy, 4 to 6 lines in diameter | 2. <i>japonica</i> |
| Leaves, four to six; capsule-globose | 3. <i>armillica</i> |
| Ovules, in pairs in each cell (<i>Prospero</i> , Salisb.); bracts, obsolete; leaves, produced after the flowering is over; pedicels, 2 to 4 inches long; leaves, nearly cylindrical, $\frac{1}{2}$ line in diameter | 4. <i>autumnalis</i> |
| Leaves, linear-lance-shaped | 5. <i>obtusifolia</i> |
| Pedicels, 12 to 21 lines long | 6. <i>Humboldtii</i> |
| Bracts, solitary; leaves, produced along with the flowers; flowers, small, from 1 to 2 lines long; leaves, fleshy-herbaceous, smooth, with sunken veins; leaves, lance-shaped, $1\frac{1}{2}$ to $2\frac{1}{2}$ inches across | 7. <i>latifolia</i> |
| Leaves, thong-like, 6 to 15 lines across; leaves, two to three | 8. <i>hemorrhoidalis</i> |
| Leaves, five to eight; bracts, as long as the pedicels | 9. <i>Bertheloti</i> |
| Bracts, very minute | 10. <i>messinaica</i> |
| Leaves, linear thong-like, 2 to 4 lines across | 11. <i>pratensis</i> |
| Leaves, stiff and leathery, with veins raised in relief; leaves, pubescent; perianth, white | 12. <i>Gerrardi</i> |
| Leaves, smooth; perianth, rosy-purple | 13. <i>primifolia</i> |
| Perianth, 2 to $2\frac{1}{2}$ lines long; bracts, deltoid | 14. <i>hyacinthoides</i> |
| Perianth, 4 or 5 lines long; bracts, elongated-linear | 15. <i>Lilio-hyacinthus</i> |
| Bracts, in pairs; leaves produced along with the flowers (<i>Somera</i> , Salisb.); leaves, two, seldom three, lance-shaped | 16. <i>Acistilis</i> |
| Leaves, four to six, elongated, thong-like | 17. <i>italica</i> |
| Ovules, few or several, placed over each other in the cell; bracts, small, deltoid, sometimes obsolete; flowers, one to three, slightly drooping | 18. <i>sibirica</i> |
| Flowers, three to twelve, or more, erect; flowers, usually two, seldom three or four | 19. <i>bifolia</i> |
| Flowers, always four or five | 20. <i>ancuta</i> |
| Bracts, solitary, elongated, linear; species, natives of the Mediterranean region and Western Europe, with a sessile ovary; racemes, deltoid, or nearly in corymbs; racemes, bearing from 50 to 100 flowers | 21. <i>peruviana</i> |
| Racemes, bearing from six to fifteen (seldom twenty) flowers; leaves, ciliated at the margin; perianth, 3 lines long | 22. <i>Cypri</i> |
| Perianth, 4 to $4\frac{1}{2}$ lines long | 23. <i>villosa</i> |
| Leaves, smooth at the margin | 24. <i>verna</i> |
| Racemes, oblong; leaf, solitary | 25. <i>monophylla</i> |
| Leaves, three or four | 26. <i>admirata</i> |
| Species, natives of the Cape, with a stalked ovary; leaves, stiff and leathery, with veins raised in relief; perianth, whitish; bulb, crowned on the top with numerous bristles | 27. <i>rigidifolia</i> |
| Perianth, sky-blue; bulb, without bristles | 28. <i>Kraussii</i> |
| Leaves, fleshy, herbaceous, with sunken veins; perianth, sky-blue; bracts, 9 to 12 lines long | 29. <i>notulensis</i> |
| Perianth, whitish; bracts, 2 to 3 lines long; leaves, linear, thong-like, 4 to 6 lines across | 30. <i>versicolor</i> |

- Leaves, lance-shaped, thong-like, 12 to 15 lines across ... 31. *pallidiflora*
 Bracts, deltoid, in pairs ... 32. *Hohenackeri*
 Bracts, linear, in pairs; leaves, linear, 2 to 3 lines across ... 33. *vincentina*
 Leaves, tongue-shaped, thong-like, 4 to 6 lines across ... 34. *lingulata*
 Doubtful species of this sub-genus ... 35. *lusitana*
 ... 36. *plumbea*
 ... 37. *fleriosa*

Sub-genus II. Ledebouria.—Segments of the perianth remaining united for some considerable time at the base, and forming a cup there. Filaments usually in a single series, and attached above the base of the segments.

- Flowers, small (1 to 1½, seldom 2, lines long), and usually of a roundish bell-shape; perianth, of a deep rosy-purple on the inside; leaves, broad, somewhat stalked; raceme, dense; leaves, ovate-oblong ... 38. *Sandersoni*
 Raceme, loose; leaves, ob-lanceolate ... 39. *revoluta*
 Leaves, narrow, not contracted at the base; flower-stem, slender, 1 to 3 inches high; racemes, oblong; perianth, roundish, bell-shaped; leaves, narrowly linear ... 40. *minima*
 Leaves, lance-shaped ... 41. *exigua*
 Perianth, oblong, bell-shaped ... 42. *Barberi*
 Flower-stem, stout, 5 to 6 inches high; raceme, cylindrical ... 43. *Cooperi*
 Perianth, greenish; leaves, stalked; leaves, ovate-lance-shaped ... 44. *zambesiaca*
 Leaves, thong-like ... 45. *Camerooniana*
 Leaves, oblong-lance-shaped, narrowed, from the base up, for one-third of their length ... 46. *prasina*
 Leaves, lance-shaped, scarcely narrowed at the base; perianth, roundish-bell-shaped ... 47. *Ludwigii*
 Perianth, oblong-bell-shaped ... 48. *moesta*
 Perianth, 2 or 3 lines long, roundish or oblong-bell-shaped; leaves, appearing after the flower-stem ... 49. *undulata*
 Leaves, appearing along with the flowers; racemes, over-topping the leaves; leaves, stalked, or almost so; ovary, not prolonged into a disk at the base (tropical species); leaves, rounded at the base, above the leaf-stalk ... 50. *Curreri*
 Leaves, narrowed into a wedge-shape at the base; leaves, in opposite pairs ... 51. *Richardiana*
 Leaves, three to eight, forming a rosette; leaves, obovate-oblong, obtuse ... 52. *maculata*
 Leaves, lance-shaped-oblong, acute; perianth, roundish-bell-shaped ... 53. *indica*
 Perianth, tubular-bell-shaped ... 54. *lilarina*
 Leaves, sessile, scarcely narrowed at the base; perianth, greenish; leaves, usually two, opposite ... 55. *paucifolia*
 Leaves, three or four, forming a rosette ... 56. *socialis*
 Perianth, rosy-purple on the inside ... 57. *lanceifolia*
 Leaves, as long as, or longer than, the racemes; perianth, greenish both on the inside and outside; filaments, greenish ... 58. *concolor*
 Perianth, purple on the inside; filaments, deeply coloured; leaves, linear, 4 to 9 lines broad in the middle; flower-stem, curved, 3 or 4 inches long ... 59. *linearifolia*
 Flower-stem, erect, 5 or 6 inches long ... 60. *concinna*
 Leaves, lance-shaped, thong-like, 10 to 12 lines across; leaves, glaucous, distinctly narrowed at the base ... 61. *subglauca*
 Leaves, green, scarcely narrowed at the base ... 62. *lorata*
 Leaves, tongue-shaped, lanceolate, 18 to 21 lines across, scarcely narrowed at the base ... 63. *zebrina*
 Leaves, oblong, spoon-shaped, very much narrowed at the base ... 64. *spathulata*
 Flowers, large; perianth, oblong-bell-shaped, 4 or 5 lines long; racemes, very loose; leaves, distinctly stalked ... 65. *Kirkii*
 Leaves, not stalked ... 66. *lanceolata*
 Racemes, dense; central pedicels, 6 to 8 lines long ... 67. *floribunda*
 Central pedicels, 12 to 15 lines long; racemes, containing from thirty to sixty flowers on very slender pendulous pedicels ... 68. *pendula*

- Raceme, containing from 150 to 200 flowers, on stout closely-set pedicels ... 69. *principes*
 A doubtful species of this sub-genus ... 70. *viridiflora*

Sub-genus III. Endymion.—Segments of the perianth remaining united, for a considerable time, half-way up from the base; filaments, in two distinct unequal series, and inserted above the base of the segments.

- Perianth, roundish-bell-shaped ... 71. *hispanica*
 Perianth, tubular-bell-shaped ... 72. *non-scripta*

Sub-genus I.—Euscella.

Perianth, blue, rarely purple or whitish; segments patent, wheel-like, in the fully expanded flower; filaments in a single series inserted at the lowest part of the base of the segments; ovary, sessile; cells containing two ovules or more (seldom only one); bracts, linear, solitary or in pairs; or small and deltoid; rarely obsolete.

1. *S. chinensis* (Benth. "Flor. Hong Kong").—Bulb, ovoid, 9 to 12 lines in diameter; leaves, two or three in number, produced along with the flowers, as long as, or longer than, the flower-stem, 2 or 3 lines broad, somewhat hard, many-nerved, channelled, acute; flower-stem, slender, straight, a foot, or more high; raceme, pretty dense (containing from twenty to sixty flowers) when in full bloom, from 1 to 2 inches long, and 5 or 6 lines broad; pedicels, ascending for some time, 1½ to 2 lines long, the lower one frequently in pairs; bracts, minute, whitish, lance-shaped, deltoid; perianth, 1 line long, rosy-purple; filaments, a little shorter than the segments; style, thread-like, scarcely ¼ line long; ovule, solitary in each cell; racemes of fruit, 4 to 6 inches long; capsule, top-shaped, 1½ to 2 lines long. Native of China, from Peking and Macao and Hong-Kong.

2. *S. japonica* (Baker).—Bulb, ovoid, 9 to 12 lines in diameter; leaves, two or three in number, produced along with the flowers, fleshy-herbaceous, 6 to 12 inches long, 1 to 6 lines broad, acute, gradually narrowed in the lower half; flower-stems, slender, straight, 1 to 3 feet, or more, in length; raceme, somewhat loose (containing from twenty to sixty flowers or more), 4 to 8 inches long, and an inch broad when in fruit; pedicels, ascending for some time, 5 or 6 lines long when bearing fruit; bracts, minute, linear, whitish; perianth, 1½ lines long, rosy-purple; filaments, flattened at the base, a little shorter than the segments; style, ½ inch long; ovules, one in each cell; capsule, top-shaped, 2½ to 3 lines long. Native of Japan and the Loo Choo Islands.

3. *S. numidica* (Poir. lt. Barb.).—Bulb, ovoid, 1 to 2 inches in diameter; leaves, four to six in number, fleshy-herbaceous, linear, 6 to 8 inches long, 1½ to 3 lines broad, nearly erect; flower-stems, solitary or in pairs, 6 inches to 1 foot high, straight; racemes, somewhat dense (containing from thirty to sixty flowers), 2 or 3 inches long, and 1 inch across when in fruit; pedicels, 3 to 5 lines long, ascending for some time; bracts, very small, linear, evanescent; perianth, rosy-purple, 1½ inches long; filaments, a little longer than the segments, flattened at the base; ovules, solitary in each cell; capsule, 1½ lines long, globose, deep three-furrowed. Native of Algeria.

4. *S. autumnalis* (Linn.).—Bulb, ovoid, 6 to 12 lines in diameter; leaves, five or six in number, appearing soon after the flowers, fleshy-herbaceous, almost cylindrical, channelled, 4 to 6 inches long, and ½ line across; flower-stems, one to three in number, flexuose, 2 to 6 inches high; racemes (containing from six to twenty flowers), 1½ to 2 inches long, and 6 to 10 lines across when fully expanded; pedicels, ascending for some time, the lowest ones 2 to 4 lines long; bracts, obsolete; perianth, rosy-lilac, 1½ to 2 lines long; filaments, flattened, about half the length of the segments; ovules, in pairs in each cell; capsule, globose, 1½ lines long, deeply three-furrowed; seeds, black. Native of England, and extending to Tanria, Algeria, and Syria. *S. dumetorum* (Balansa) is a variety in which the leaves begin to appear after the bursting of the capsule. *S. racemosa* (Balansa) is a stout variety, with a larger bulb and buff-coloured seeds. *S. pulchella* (Munby) is an Algerine variety, with very slender leaves appearing soon after the flowers, and about as long as the flower-stem; raceme, containing six to eight flowers, scarcely more than half-an-inch broad when in fruit; perianth, smaller and more bell-shaped.

5. *S. obtusifolia* (Poiret, lt.).—Bulb, ovoid, 12 to 18 lines in diameter; leaves, three to four in number, appearing after the flowers, somewhat leathery, smooth, distinctly many-nerved, tongue-like lance-shaped, 3 or 4 inches long, 6 to 12 lines broad, acute, thickened at the margin; flower-stems, one to four in number, flexuose, 6 to 12 inches long, reddish at the base, frequently downy; raceme, somewhat dense (containing from twenty to sixty flowers), 2 or 3 inches long, and 9 or 10 lines broad when in fruit; pedicels, ascending for some time, the lowest ones 3 or 4 lines long; bracts, obsolete; perianth, rosy-lilac, 1½ to 2 lines long; filaments, flattened

at the base, a little shorter than the segments; ovules, in pairs in each cell; capsule, $1\frac{1}{2}$ lines long, globose, three-furrowed; seeds, black. Native of Algeria. A more slender variety, *S. o. intermedia* (Baker), is found in Sardinia and Corsica. It has a smaller bulb; leaves, 15 to 18 lines long and 3 or 4 lines broad; and a loose raceme of from six to fifteen flowers. Another variety, *S. o. fallax* (Baker), intermediate between *S. obtusifolia* and *S. autumnalis*, resembles the type in its height and bulb, but has longer and narrower leaves (5 to 6 inches long, and $1\frac{1}{2}$ to 2 lines broad). Native of Algeria and Morocco.

6. *S. Hanburii* (Baker).—Bulb, ovoid, 1 inch in diameter; leaves, produced after the raceme (I have not seen full-grown ones), narrowly-linear, fleshy-herbaceous; flower-stem, straight, 3 to 5 inches long; raceme, loose, 2 or 3 inches in length and breadth, containing from fifteen to twenty-five flowers; bracts, obsolete; lowest pedicels, ultimately straight, patent, 12 to 21 lines long; upper ones, ascending; perianth, 2 lines long, with narrowly strap-shaped segments, half a line broad; filaments, a little shorter than the segments; ovules, in pairs in each cell; capsule, 2 lines long, obovoid, three-furrowed, obtuse; style, thread-like, half-an-inch long. Found on Anti-Libanus at an altitude of 4,000 feet.

7. *S. latifolia* (Willd.).—Bulb, ovoid, $1\frac{1}{2}$ to 2 inches in diameter; leaves, six to nine in number, sheathing the base of the flower-stem for some distance, lance-shaped, slightly fleshy-herbaceous, 12 to 15 inches long, $1\frac{1}{2}$ to $2\frac{1}{2}$ inches broad in the middle, gradually narrowed at the base and apex, smooth on the margin, with very many slender sunken veins; flower-stem, straight, a foot or more high; raceme, dense (containing from thirty to sixty flowers), 3 or 4 inches long, and 12 to 15 lines across, when fully expanded; lowest pedicels, somewhat patent, 5 to 7 lines long; bracts, very small, linear awl-shaped; perianth, lilac, bell-shaped, $1\frac{1}{2}$ lines long, with strap-shaped segments half a line broad; ovules, in pairs in each cell; filaments, a little shorter than the segments. I have not seen the capsule. Native of the Canary Islands and Madeira. *S. lusitanica* (Sims, Bot. Mag. t. 1993, non Linn.) is, probably, a robust garden variety of this species.

8. *S. hæmorrhoidalis* (Webb).—Bulb, ovoid, 12 to 15 lines in diameter, with numerous tawny membranous coats; leaves, two or three in number, produced along with the flowers, thong-like, slightly fleshy-herbaceous, 6 to 12 inches long, 6 to 15 lines broad, narrowed abruptly at the apex, and for a considerable length at the base, smooth at the margin, and with slender sunken veins; flower-stem, 4 to 9 inches long; raceme (containing from twenty to fifty flowers), 4 to 8 inches long, and 8 to 12 lines broad, when fully expanded; bracts, linear awl-shaped, 1 to $1\frac{1}{2}$ lines long; pedicels, erect-patent, the lowest ones 2 or 3 lines long; perianth, lilac, bell-shaped, $1\frac{1}{2}$ lines long, with strap-shaped segments downy at the apex; filaments, scarcely 1 line long; ovules, two in each cell; capsule, 2 lines long, depressed-globose, obtusely triangular. Native of the Canary Islands.

9. *S. Bertheloti* (Webb).—Bulb, of a long ovoid shape, 6 to 9 lines in diameter; leaves, five or six in number, produced together with the flowers, slightly fleshy-herbaceous, patent, thong-like, 6 to 12 inches long, and 6 to 9 lines broad in the middle, narrowed abruptly at the apex and for some length at the base, and marked with slender sunken veins; flower-stems, slender, 6 to 8 inches high; racemes (containing twelve to twenty flowers each), when fully expanded, 1 to 2 inches long, and 5 or 6 lines across; bracts, awl-shaped, 1 line long; pedicels, ascending, as long as the bracts; perianth, bell-shaped, pale lilac, 1 line long, with ligulate lance-shaped segments; filaments, a little shorter than the segments; ovules, 2 in each cell, collateral; style, thread-like, as long as the ovary; capsule, globose, obtusely three-angled. Canary Islands and Western Guinea. Flowered in Kew Gardens in 1860.

10. *S. messeniaca* (Boiss.).—Bulb, ovoid, with pale coats; leaves, five to seven in number, thong-like, 12 to 18 inches long, 4 to 10 lines broad, with from twenty-four to thirty-six nerves, narrowed abruptly at the apex, and for some length at the base; flower-stem, slender, about as long as the leaves; raceme, ovate-oblong, containing from seven to twelve flowers; bracts, linear, solitary, very minute; pedicels, erect-patent, half as long again as the flowers; segments of the perianth, linear, obtuse, of a pale azure colour, marked with a deeper line in the middle; filaments, sky-blue, flattened at the base; ovules, in pairs in each cell; style, as long as the ovary. Greece, Peloponnesus.

11. *S. pratensis* (Lindl. "Bot. Reg." 1839, t. 63).—Bulb, ovoid, 9 to 12 lines in diameter; leaves, three to six in number, produced along with the flowers, fleshy-herbaceous, smooth, narrowly-strap-shaped, 6 to 12 inches long, 2 to 4 lines broad, with from ten to twenty sunken veins, and gradually from the middle towards the apex and base; raceme, dense (containing from twelve to thirty flowers) when fully expanded, $1\frac{1}{2}$ to $2\frac{1}{2}$ inches long, and from 15 to 18 lines

across; bracts, very small, deltoid, solitary; pedicels, 4 to 6 lines long, ascending or somewhat patent; perianth, bell-shaped, $1\frac{1}{2}$ to 2 lines long, of a deep sky-blue colour, with segments $\frac{1}{2}$ inch wide; filaments, 1 to $1\frac{1}{2}$ lines long, flattened in the upper part; ovules, in pairs in each cell; capsule, globose. Croatia, Bosnia, Dalmatia.

12. *S. Gerrardi* (Baker).—Bulb, ovoid, 8 or 9 lines in diameter, crowned with numerous brownish bristly fibres; leaves three or four in number, produced along with the flowers, linear, ascending, 3 to 5 inches long, 1 to $1\frac{1}{2}$ lines broad, covered everywhere with a grey pubescence, stiff and leathery, persistent, thickened at the margin, and marked on the upper surface with five or six raised nerves, which stand out in bold relief; flower-stem, pubescent, straight, 4 to 6 inches long; raceme, somewhat dense (containing from twenty to thirty flowers), when fully expanded, 2 or 3 inches long, and 18 to 21 lines across; bracts, solitary, linear-awl-shaped, $1\frac{1}{2}$ to 2 lines long; pedicels, ascending, stout, 6 to 9 lines long; perianth, white, $1\frac{1}{2}$ lines long, with bluntish segments half-a-line broad, and slightly hooded at the apex; filaments 1 line long, linear at the base; capsule, of a depressed globose shape, deeply three-angled, 1 line long; seeds, solitary in each cell. Natal and British Caffraria.

13. *S. firmifolia* (Baker).—Bulb, ovoid, 12 to 15 lines in diameter; leaves, produced along with the flowers, three or four in number, stiff and leathery, smooth, nearly erect, linear, 5 or 6 inches long, $1\frac{1}{2}$ to 2 inches broad, convex on the back, channelled on the upper surface, and marked with very prominent veins standing out in relief; flower-stems, firm, 5 or 6 inches high; racemes, somewhat dense (each containing from thirty to fifty flowers), when expanded, of a cylindrical lance-shape, 3 or 4 inches long, and 6 or 7 lines across; bracts, linear, lance-shaped, $\frac{1}{2}$ to 1 line long, the lowest ones $1\frac{1}{2}$ to 2 lines long; pedicels, ascending, the lower ones $1\frac{1}{2}$ to 2 lines long; perianth, roundish-bell-shaped, of a deep rosy-purple colour, $1\frac{1}{2}$ lines long, with lance-shaped segments, $\frac{1}{2}$ line across; ovules, two in each cell; filaments, 1 line long, lance-shaped at the base. Cape of Good Hope.

14. *S. hyacinthoides* (Linn.).—Bulbs, large, gregarious, ovoid, $1\frac{1}{2}$ to 2 inches in diameter; leaves, ten to twelve in number, produced along with the flowers, fleshy-herbaceous, patent, 12 to 18 inches long, 6 to 15 lines broad, narrowed, abruptly at the apex, and for some distance at the base, minutely toothed at the margin; flower-stem, straight, 1 to 2 feet, or more, high; raceme (containing from fifty to 150 flowers), when fully expanded, 6 to 18 inches long, and 2 to 2½ inches across; bracts, small, deltoid, whitish, persistent; pedicels, erect-patent, the lower ones 12 to 15 inches long; perianth, of a deep lilac-blue, 2 to $2\frac{1}{2}$ lines long, with strap-shaped segments, downy at the apex; filaments, $1\frac{1}{2}$ to 2 lines long, flattened in the upper part; ovules, collateral, in pairs in each cell; style, thread-like, $1\frac{1}{2}$ inches long; capsule, globose. Portugal; thence through the Mediterranean region, to Syria.

15. *S. Lilio-hyacinthus* (Linn.).—Bulb, ovoid, 15 to 18 lines in diameter, covered with broad, ovate, lilac-coloured scales; leaves, four to six in number, produced along with the flowers, fleshy-herbaceous, flaccid, smooth, sheathing the flower-stem for a considerable length at the base, 6 to 12 inches long, 8 to 12 lines broad, narrowed abruptly at the apex, and gradually in the upper part; flower-stem, slender, 6 to 12 inches long; racemes (containing from six to eighteen flowers), 2 or 3 inches long, and from 15 to 18 lines broad when fully expanded; pedicels, erect-patent, the lowest ones from 6 to 12 lines long; bracts, linear, solitary, persistent, 6 to 9 lines long; perianth, bell-shaped, of a deep blue colour, 4 or 5 lines long, with lance-shaped segments, 1 to $1\frac{1}{2}$ lines across; ovules, in pairs in each cell; filaments, $2\frac{1}{2}$ to 3 lines long; style, 2 lines long; capsule of a depressed-globose shape, obtusely three-angled, 4 lines in length and width. Central and Southern France, and the north of Spain.

16. *S. Aristidis* (Cosson).—Bulb, ovoid, 5 or 6 lines in diameter; leaves, two or three in number, produced along with the flowers, fleshy-herbaceous, smooth, lance-shaped, acute, 5 or 6 inches long, 4 to 6 lines broad, embracing the base of the flower-stem, which is solitary, and a little longer than the leaves; raceme, dense (containing from ten to twelve flowers), and, when fully expanded, 12 to 15 lines long and 5 or 6 lines across; bracts, in pairs, linear, whitish, 3 or 4 lines long; pedicels, ascending, the lowest ones 2 or 3 lines long; perianth, $2\frac{1}{2}$ to 3 lines long, with segments scarcely a line wide; filaments, $1\frac{1}{2}$ lines long; ovules, in pairs in each cell; style, 1 line long. Algeria. This species has quite the habit of *S. lingulata*; but is easily distinguished from it by its fewer leaves, and its ovules being in pairs.

17. *S. italica* (Linn.).—Bulb, ovoid, 6 to 9 lines in diameter; leaves, four to six in number, thong-like, fleshy-herbaceous, flaccid, patent, sharply keeled, 4 to 8 inches long, 3 to 6 lines broad, narrowed abruptly at the apex, and gradually on the upper part; flower-stems, solitary, slender, 6 to 10 inches high; racemes, dense (containing from six to thirty flowers), at first conical in shape,

when fully expanded, 1 or 2 inches long, and 9 to 12 lines broad; bracts, in pairs, linear, 4 to 6 lines long; pedicels, erect-patent, the lowest ones 3 to 6 lines long; perianth, of a deep blue colour, and with a Willow-like odour, $2\frac{1}{2}$ to 3 lines long, with segments half-a-line broad, and downy at the apex; filaments, $1\frac{1}{2}$ to 2 lines long, narrowly wedge-shaped at the base; ovules, two in each cell; capsule, globose, obtusely three-angled. Italy, Switzerland, Baden, and Southern France. *S. purpurea* (Mill.) is a robust garden form, with deeper coloured flowers.

18. *S. sibirica* (Andrews).—Bulb, globose, 6 to 15 lines in diameter; leaves, two to four in number, produced along with the flowers, fleshy-herbaceous, ascending, thong-like, when fully grown, 4 to 6 inches long and 4 to 6 lines broad, narrowed abruptly at the apex, slightly hooded, gradually narrowed in the upper part, and with twelve to twenty sunken veins; flower-stems, one to six in number, fleshy, 3 to 6 inches high; flowers, one to three on each stem, horizontal, or slightly nodding, lateral, on short stalks; bracts, small, deltoid; perianth, of a brilliant porcelain-blue colour, 6 or 7 lines long, with segments $1\frac{1}{2}$ to 2 lines broad, ascending in the fully expanded flower, and of a deeper colour on the back; filaments, 3 to $3\frac{1}{2}$ lines long, flattened at the base; ovules, eight to ten in each cell; style, $1\frac{1}{2}$ to 2 lines long. Southern and Central European Russia, thence extending to Armenia, Georgia, and Kurdistan.

19. *S. bifolia* (Linn.).—Bulb, ovoid, 6 to 9 lines in diameter; leaves, produced along with the flowers, most usually in an opposite pair, embracing the base of the flower-stem for some length, fleshy-herbaceous, hooded and narrowed abruptly at the apex, and gradually on the upper part, when fully grown, 4 to 8 inches long, and 4 to 6 lines across, concave on the upper surface; flower-stems, solitary, 3 to 6 inches long; racemes, deltoid, containing each three to eight flowers, and, when, fully expanded, 1 to $1\frac{1}{2}$ inches broad; pedicels, ascending, the lowest ones 6 to 12 lines long; bracts, small, deltoid, sometimes obsolete; perianth, of a deep brilliant blue, sometimes reddish or whitish, 4 or 5 lines long, with segments 1 to $1\frac{1}{4}$ lines broad, patent in the fully-expanded flower; filaments, $2\frac{1}{2}$ to 3 lines long, flattened at the base; ovules, five or six in each cell; style, 1 line long; capsule, globose, 3 or 4 lines in length and breadth, obtusely three-angled; seeds, two to four in each cell, of a tawny colour, and furnished at the base with a whitish fleshy arillus. Spain and France, and thence extending to Asia Minor and Georgia. *S. Kladnii* (Schur.) is a small, decumbent, few-flowered, Alpine, bifoliate form.

Var. *s. b. præcox* (Masters).—A more robust form, with an ovoid bulb 1 inch in diameter, and bearing ten to fifteen flowers, a little larger and blooming earlier; the leaves are thicker and broader, and the lowest pedicels are from 1 to $1\frac{1}{2}$ inches long. Native of Austria. *S. rosea* (Lehm.) is a form of this variety with reddish flowers. *S. b. var. taurica* (Regel) is a Taurian form, usually producing three or four leaves.

Var. *s. b. nivalis* (Baker).—A more slender variety, from the mountains of Greece and Asia Minor, with two leaves, 2 to 3 lines broad, and two to five flowers, with smaller segments, which are scarcely more than 3 lines long. *S. laxa* and *S. subtriphylla* (Schur.) are allied forms, from the mountains of Transylvania, with usually from three to five leaves.

20. *S. amœna* (Linn.).—Bulb, sub-globose, 6 to 9 lines in diameter; leaves, four to five in number, produced along with the flowers, fleshy-herbaceous, flaccid, thong-like, embracing the base of the flower-stem, ascending, smooth, 6 to 9 inches long, and 4 to 8 lines broad, narrowed abruptly at the apex and for some distance in the upper part, and marked with from twenty to thirty slender sunken veins; flower-stems, weak, 4 to 6 inches high; raceme, loose, containing three to six flowers, and, when fully expanded, from 6 to 9 lines long; bracts, small, deltoid; pedicels, ascending, the lowest ones 6 to 9 lines long; perianth, 5 to 6 lines long, of a deep blue colour (rarely whitish), and with lance-shaped segments, 1 to $1\frac{1}{2}$ lines broad; filaments, 3 lines long, flattened at the base; ovules, six to eight in each cell; style, blue, $1\frac{1}{2}$ to 2 lines long; capsule, sub-globose, obtusely three-angled, and with not very deep furrows. Austria, Germany, and Northern Italy.

Var. *S. a. bithynica* (Baker).—A more slender form, with leaves 3 or 4 lines broad, and marked with ten to fifteen nerves; perianth, 3 lines long. Mountains of Asia Minor.

21. *S. peruviana* (Linn.) (*Calosilla hipponensis*, &c., Jourd. et Fourr.).—Bulb, ovoid, 2 or 3 inches in diameter, with numerous coats; leaves, six to nine in number, produced along with the flowers, thong-like, fleshy-herbaceous, 6 to 12 inches long, and 8 to 12 lines broad, narrowed from the middle towards the base and apex, and fringed on the margin with dense small whitish bristles; flower-stem, stout, striated, 6 to 12 inches high; raceme, very dense, containing from fifty to a hundred flowers, or more, and, at first, of a deltoid shape; when fully expanded, 4 to 6 inches in length and breadth; bracts,

linear, whitish, persistent, solitary, 1 to 2 inches long, very conspicuous before the flowering begins; lowest pedicels, sub-patent, 2 or 3 inches long; perianth, 5 to 6 lines long, lilac, reddish, or whitish, with lance-shaped segments, channelled with green, and $1\frac{1}{2}$ to 2 lines broad; ovules, four to six in each cell; filaments, lance-shaped, 3 to 4 lines long; capsule, tep-shaped. Sardinia, Corsica, Sicily, Italy, and Algeria. *Calosilla hipponensis*, subcarnea, and *elegans* (Jourd. et Fourr.), are Algerian forms with reddish flowers; and *C. pallidiflora*, flaveola, and subalbida, are forms with whitish flowers.

Var. *S. p. glabra* (Boiss.).—Leaves, smooth on the margin; lower pedicels, $1\frac{1}{2}$ to 2 inches long; perianth, of a deep lilac colour. Spain, Portugal, and Mauritania. *Scilla Hnghii*, from the island of Marettini, near Sicily, is a more robust form, with the flower-stem, pedicels, and bracts tinged with red, and leaves from $1\frac{1}{2}$ to 2 inches broad.

22. *S. Cupani* (Guss. Prodr.).—Bulb, ovoid, from 9 to 12 lines in diameter; leaves, six to eight in number, produced along with the flowers, thong-like, lance-shaped, fleshy-herbaceous, patent, 3 to 4 inches long, 6 to 8 lines broad in the middle, transparent at the margin and minutely ciliated; flower-stem, slender, flexuose 3 to 6 inches high; raceme, loose, containing six to twelve flowers, sub-corymbose or deltoid in shape, and, when fully expanded, $1\frac{1}{2}$ to 2 inches in length and breadth; bracts, whitish, slightly fringed, lance-shaped, solitary, acuminate, 6 to 9 lines long; pedicels, ascending, the lowest ones 1 to 2 inches long; perianth, of a deep blue colour, 3 lines long, with oblong-obtuse segments, 1 line broad; filaments, $1\frac{1}{2}$ lines long, flattened at the base; ovules, few, placed over each other; capsule, obovoid, obtusely three-angled. Sicily.

23. *S. villosa* (Desf.).—Bulb, ovoid, 8 to 9 lines in diameter; leaves, three or four in number, produced along with the flowers, thong-like, fleshy-herbaceous, patent, 3 to 5 inches long, 3 to 6 lines broad, ciliated, slightly hairy on the upper surface, and channelled; flower-stem, 2 or 3 inches high; raceme, sub-corymbose, and containing from six to eight flowers; bracts, solitary, linear, persistent, 6 to 9 lines long; pedicels, erect-patent, the lowest ones 9 to 15 lines long; perianth, of a deep blue colour, 4 to $4\frac{1}{2}$ lines long, with elliptical bluntish segments, $1\frac{1}{2}$ lines broad; filaments, $2\frac{1}{2}$ to 3 lines long; ovules, four or five in each cell. Barbary.

24. *S. verna* (Huds. Fl. Angl.).—Bulb, ovoid, 6 to 9 lines in diameter; leaves, four to six in number, fleshy-herbaceous, flaccid, produced along with the flowers, patent, smooth, linear, 3 to 8 inches long, 1 to $1\frac{1}{2}$ lines broad, sub-obtuse, gradually narrowed downwards; flower-stem, slender, 3 to 6 inches high; raceme, sub-corymbose or deltoid, containing from six to twelve flowers, and, when fully expanded, 9 to 18 lines across; bracts, solitary, linear, whitish, 3 to 6 lines long; pedicels, erect-patent, the lowest ones from 6 to 12 lines long; perianth, bell-shaped, of a deep blue colour, $2\frac{1}{2}$ to 3 lines long, with lance-shaped segments, 1 to $1\frac{1}{2}$ lines broad; ovules, four to six in each cell; filaments, lance-shaped, 2 lines long; capsule, globose, top-shaped, $2\frac{1}{2}$ to 3 lines in length and breadth. Native of the British Islands, and distributed northwards to the Faroe Islands, and southward through France to the North of Spain. A variety, *S. v. Rambrei* (Baker), is of more robust growth, with leaves 2 or 3 lines broad, and bears from twelve to twenty flowers, disposed in large racemes. Spain and Portugal.

25. *S. monophylla* (Link in "Sehrad. Journ.," 1799).—Bulb, globose, 6 to 9 lines in diameter; leaf, usually solitary, sheathing the base of the flower-stem for some distance, ascending, thong-like, fleshy-herbaceous, 6 to 9 inches long, 6 to 8 lines broad in the middle, and gradually narrowed towards the acute apex; flower-stem, slender, 6 to 12 inches high; racemes, loose, containing from five to twenty flowers each, and, when fully expanded, 2 or 3 inches long, acuminate, solitary, whitish; pedicels, ascending, the lowest ones from 6 to 12 lines long; perianth, bell-shaped, 3 or 4 lines long, with segments from 1 to $1\frac{1}{4}$ lines broad; ovules, four to six in each cell; filaments, 2 to 2½ lines long, flattened at the base; capsule, globose, top-shaped, obtusely triangular, 4 lines in length and breadth. Spain, Portugal, and Morocco.

26. *S. odorata* (Hoffm. et Link.).—Bulb, ovoid, 6 to 9 lines in diameter; leaves, three or four in number, produced along with the flowers, smooth, 6 to 9 inches long, 3 or 4 lines broad, sub-obtuse, channelled on the upper surface, narrowed downwards for a considerable length; flower-stem, slender, flexuose, 3 to 6 inches high; racemes, loose, containing from six to twenty flowers each, and, when fully expanded, from 1 to $2\frac{1}{2}$ inches long, solitary, deltoid at the base; pedicels, ascending, the lowest ones 4 to 6 lines long; perianth, bell-shaped, fragrant, of a deep blue colour, 4 to $4\frac{1}{2}$ lines long, with oblong segments, $1\frac{1}{2}$ lines broad; ovules, five or six in each cell; filaments, 3 lines long, flattened at the base; capsule, globose, obtusely three-angled. Spain and Portugal.

27. *S. rigidifolia* (Kunth, "Ennm." iv. 330).—Bulb, ovoid, 1 or 2 inches in diameter, crowned with numerous persistent fibrous

bristles; leaves, five or six in number, produced along with the flowers, stiff and leathery, ascending, thong-like lance-shaped, undulated, smooth, with thickened edges and very prominent veins, 8 to 12 inches long, 6 to 12 lines broad in the middle, gradually narrowed towards the pointed apex; flower-stem, straight, 6 to 12 inches long; raceme, dense (containing thirty to a hundred flowers, or more), conical at first, and, when fully expanded, 3 to 6 inches long, and $1\frac{1}{2}$ to 2 inches broad; bracts, linear, 2 or 3 lines long; pedicels, stout, ascending, the lower ones 9 to 18 lines long; perianth, whitish, bell-shaped, $1\frac{1}{2}$ to 2 lines long, with oblong, slightly hooded segments half a line broad; filaments, 1 to $1\frac{1}{2}$ lines long, hardly flattened; ovules, six to eight in each cell; ovary, globose, shortly stalked; styles as long as the ovary. Cape of Good Hope, Natal, the Transvaal territory, and Basuto land, and on the banks of the river Amapages. A variety, *S. r. nervosa* (Baker), is a taller and more robust grower, with an ovoid raceme, which, when fully expanded, is 7 or 8 inches long, and 4 or 5 inches broad, with straight, horizontally patent pedicels, 2 to $2\frac{1}{2}$ inches long. Cape of Good Hope. Grown in Kew Garden in 1858.

28. *S. Kraussii* (Baker).—Bulb, elongated ovoid, 9 to 12 lines in diameter, devoid of bristles on the crown; leaves, three or four in number, produced along with the flowers, stiff and leathery, densely pubescent on both sides, undulated, lance-shaped, $1\frac{1}{2}$ to 2 inches long, 5 or 6 lines broad, with thickened edges and prominent veins; flower-stem, firm, 6 to 8 inches high; raceme, dense (containing from twenty to fifty flowers), $1\frac{1}{2}$ to 3 inches long, and about an inch in diameter; bracts, solitary, linear awl-shaped, 3 or 4 lines long; pedicels, slender, ascending, lower ones 4 to 6 lines long; perianth, bell-shaped, blue, $1\frac{1}{2}$ to 2 inches, with bluntish lance-shaped segments, three-quarters of a line broad; ovary, globose, very shortly stalked; ovules, few, arranged over each other in each cell; style, thread-like, as long as the ovary; filaments, 1 line long, flattened at the base. Natal.

29. *S. natalensis* (Planch. in "Bot. Mag." t. 5, 379).—Bulb, ovoid, 3 or 4 inches in diameter, with scaly coats at the crown, but no fibres; leaves, four to six in number, fleshy-herbaceous, produced along with the flowers, thong-like, lance-shaped, of a deep green colour, smooth, 9 to 12 inches long, 3 or 4 inches broad, ascending, gradually narrowed towards the pointed apex; flower-stem, stout, erect, tapering, 1 to $1\frac{1}{2}$ feet high, and 4 to 6 lines in diameter; raceme, dense, containing from 50 to 100 flowers or more, and when fully expanded, 6 to 12 inches long and $2\frac{1}{2}$ to 3 inches in diameter; pedicels, ascending, the lower ones from 9 to 12 lines long; bracts, solitary, linear-awl-shaped, 9 to 12 lines long; perianth, deep blue, 3 or 4 lines long, with spreading star-like segments, 1 to $1\frac{1}{2}$ lines broad; filaments, linear, 2 to $2\frac{1}{2}$ lines long; ovary, globose, shortly stalked; ovules, ten to twelve in each cell; style, thread-like, 1 line long. Natal. It has been grown in Kew Gardens, together with its variety, *S. N. sordida* (Baker), which is smaller, and has brownish-tinged, fewer, and smaller leaves, 7 or 8 inches long, and 15 to 18 lines broad, a more slender flower-stem, and perianth $2\frac{1}{2}$ to 3 lines in length.

30. *S. versicolor* (Baker).—Bulb, ovoid, 1 to $1\frac{1}{2}$ inches in diameter, tunicated at the crown; leaves, six to eight in number, produced along with the flowers, fleshy-herbaceous, smooth, ascending, linear-thong-like, 6 to 9 inches long, 4 to 6 lines broad, green on both sides, and gradually narrowed towards the acute apex; flower-stem, erect, 6 to 8 inches high; raceme, somewhat dense, containing from fifty to eighty flowers, and when fully expanded 6 to 8 inches long, and $3\frac{1}{2}$ inches across, with a thickened rachis; bracts, solitary, linear, 2 or 3 lines long; lower pedicels eventually patent, $1\frac{1}{2}$ to 2 inches long; perianth, 2 to $2\frac{1}{2}$ lines long, whitish tinged with green, and with bluntish strap-shaped segments half line broad; filaments, $1\frac{1}{2}$ to 2 lines long, slightly flattened; anthers, blue; ovules, five or six in each cell; ovary, globose, blue, very shortly stalked; style as long as the ovary.—Cape of Good Hope. Has been grown in Mr. Wilson Saunders's garden.

31. *S. pallidiflora* (Baker).—Bulb, ovoid, 3 or 4 inches in diameter, the outer coats devoid of fibrous bristles at the apex; leaves, five or six in number, produced along with the flowers, fleshy-herbaceous, thong-like, lance-shaped, ascending, 12 to 15 inches long, 12 to 15 lines broad, smooth, green, with sunken veins; flower-stem, stout, erect, $1\frac{1}{2}$ feet or more high; raceme, dense, containing from 100 to 150 flowers or more, conical at first, and, when fully expanded, 6 to 10 inches long, and 3 inches in diameter; bracts, solitary, linear, small; pedicels, straight, the lower ones horizontally patent, 12 to 15 lines long; perianth, bell-shaped, whitish tinged with green, and with bluntish oblong segments; filaments, thread-like, $1\frac{1}{2}$ lines long; ovary, globose, very shortly-stalked; ovules, numerous, arranged over each other in the cell; style, nearly as long as the ovary.—Cape of Good Hope.

32. *S. Hohenackeri* (Fisch. et Mey.).—Bulb, ovoid, 6 to 12 lines

in diameter; leaves, 4 to 6 in number, produced along with the flowers, fleshy-herbaceous, flaccid, smooth, narrowly thong-like, 8 to 12 inches long, $1\frac{1}{2}$ to 3 lines broad, narrowed abruptly at the apex, and thence gradually downwards; flower-stems, one or two in number, slender, 1 to 8 inches high; racemes, loose, containing from six to fifteen flowers each, and when fully expanded, 2 or 3 inches long, and 15 to 18 lines broad; bracts, in pairs, whitish, membranous, truncate, half a line long, spurred at the base; pedicels, sub-patent, or nodding, the lowest ones 5 or 6 lines long; perianth, blue, 5 or 6 lines long, with strap-shaped segments, $1\frac{1}{2}$ lines broad, bluntish and slightly hooded at the apex; filaments, thread-like, 3 or 4 lines long; ovary, globose, very shortly stalked; style, thread-like, 2 lines long; capsule, sub-globose, 3 lines long; seeds, three or four in each cell.—Caucasus, Afghanistan, and the East Indies.

33. *S. vincentina* (Hoffm. et Link.).—Bulb, sub-globose, 6 to 9 lines in diameter, leaves three or four in number, fleshy-herbaceous, flaccid, smooth, linear, sheathing the base of the flower-stem, ascending, 1 to 8 inches long, 2 or 3 lines broad, gradually narrowed towards the pointed apex; flower-stem, slender, 1 to 6 inches high; racemes, sub-corymbose, each containing from six to eighteen flowers; bracts, linear, in pairs, the lower ones 6 to 9 lines long; pedicels, ascending, the lowest ones 6 to 9 lines long; perianth, bell-shaped, deep blue, $2\frac{1}{2}$ to 3 lines long, with lance-shaped segments 1 line broad, filaments, lance-shaped, $1\frac{1}{2}$ to 2 lines long; ovules, 2 or 3 in each cell.—Portugal and Morocco. This species has quite the habit of *S. verna*, but is distinguished by having the bracts in pairs, and by the different shape of the leaves.

34. *S. lingulata* (Poir.).—Bulb, ovoid, 6 to 8 lines in diameter; leaves, six to eight in number, produced along with the flowers, fleshy-herbaceous, smooth, ascending, tongue-shaped, thong-like, embracing the base of the flower-stem, 2 or 3 inches long, 4 to 6 lines broad, narrowed abruptly at the apex, and thence gradually downwards; flower-stem, 2 to 4 inches high; raceme, oblong, somewhat dense, containing from six to fifteen flowers, and, when fully expanded, 12 to 18 lines long, and 6 to 9 lines in diameter; bracts, linear, in pairs, 6 to 9 lines long; pedicels, erect-patent, the lowest ones 2 or 3 lines long; perianth, bell-shaped, $2\frac{1}{2}$ to 3 lines long, with bluntish strap-shaped segments $\frac{1}{2}$ to 1 line broad; ovules, three or four in each cell; filaments, $1\frac{1}{2}$ to 2 lines long; capsule, globose-top-shaped, 2 to $2\frac{1}{2}$ lines in length and breadth.—Algeria and Morocco.

Doubtful Species of this Sub-genus.

35. *S. lusitanica* (Linn.).—Leaves, fleshy-herbaceous, thong-like, 5 or 6 inches long, 6 or 7 lines broad, smooth, flaccid; flower-stem, 4 or 5 inches high; raceme, 2 or 3 inches long, 15 to 18 lines broad, and containing from twenty to thirty flowers; bracts, solitary, linear, membranous, whitish, $1\frac{1}{2}$ to 2 lines long; pedicels, ascending, the lower ones 9 to 12 lines long; perianth, whitish, 3 lines long, with lance-shaped segments more than a line across; stamens, lance-shaped, $1\frac{1}{2}$ lines long.—Portugal, on the authority of Linnaeus. I have examined the original specimen from the garden at Upsal, in the herbarium of Linnaeus, but have seen no ovules. The plant appears to approach *S. italica* in habit, but differs in having shorter and solitary bracts, and broader leaves, &c.

36. *S. plumbea* (Lindl.).—Bulbs, gregarious, ovoid, 2 or 3 inches in diameter; leaves, fleshy-herbaceous, produced along with the flowers, thong-like, lance-shaped, about 1 foot long, and 15 lines broad, not spotted, acute, smooth; raceme, containing from fifteen to twenty flowers, and, when fully expanded, 3 to $3\frac{1}{2}$ inches long, and 18 to 21 lines broad; bracts, linear, 2 or 3 lines long; lowest pedicels sub-patent, 6 to 8 lines long; perianth of a dull blue colour, bell-shaped, 3 to $3\frac{1}{2}$ lines long. Cape of Good Hope. I have not seen the plant, and the above description is that of a specimen grown in Kew Gardens in 1813. It appears to approach closely to *S. natalensis*, and I am in doubt if it is not the same.

37. *S. flexuosa* (Baker).—Leaves, produced along with the flowers, smooth, fleshy-herbaceous, attaining the length of 1 foot and 1 line broad, flexuose, sheathing the base of the flower-stem for a considerable length; flower-stem, flexuose, slender, 6 inches high; raceme, containing from ten to twelve flowers, and when fully expanded, 15 to 18 lines long, and 1 inch in diameter; bracts, lance-shaped, membranous, persistent, as long as the pedicels; pedicels, slender, flexuose, the lower ones 4 or 5 lines long; perianth, bell-shaped, $2\frac{1}{2}$ lines long, with lance-shaped segments, three-quarters of a line broad; stamens a little shorter than the segments. Cape of Good Hope.

[The foregoing descriptive enumeration of Squills, translated for THE GARDEN, forms the first part of Mr. Baker's excellent paper on that genus, printed in a late number of the *Linnean Society's Journal*. The remainder of the article we hope to publish next week.—Ed.]

GARDENING FOR THE WEEK, AND AMATEUR'S CALENDAR.

The Flower Garden and Pleasure Grounds.

LET every effort be used to render the flower garden as interesting and attractive as possible; let beds of Verbenas and Calceolarias still be well supplied with water while the weather continues dry, or the former will become the prey of red spider, while the latter will be not unlikely to die off altogether. Zonal Pelargoniums, when fairly established, will continue healthy and will flower well with a somewhat restricted supply of moisture; the tricolor sorts, which are generally grown for the beauty of their foliage only, should be divested of their blooms before they expand, and should be encouraged by every possible means to grow freely. Continue to thin, stake, and tie up the shoots of Dahlias and other tall-growing herbaceous plants wherever this is required; also remove decayed leaves and flower-stems as soon as the flowering period is over; and it is very likely that many species of Larkspur and other hardy plants will, this season, flower freely for the second time in the course of the autumn. Many annual flowers have been of short duration this year; they should, however, be cleared off as soon as they are out of bloom, unless seed is required, and this should never be saved promiscuously, or the "strain" will gradually deteriorate, as it generally happens that the worst flowers are the most productive of seed. If new and distinct varieties are desired recourse must be had to artificial fertilisation; but if improvement of strain is merely what is sought for, that can, with more or less certainty, be secured by judicious selection, a practice which should be invariably pursued with annual flowers generally, and more particularly with such plants as the various sorts of Stocks and Wallflowers, Mignonette, Anemones, Columbines, Antirrhinums, Pinks, Larkspurs, Helichrysums, Phlox Drummondii, &c., as, by this means, annual flowers, as well as culinary vegetables of various kinds may be brought to a very high degree of excellence. The marking of the selected blooms may be effected by attaching to them small pieces of coloured worsted or some such material; and the seed produced by the marked blooms should be carefully collected as soon as fairly ripe. Where the production of hybrids or cross-bred plants is attempted, fecundation must be induced artificially, an operation which requires considerable care, and as a *sine qua non* to success, it is necessary that the blooms selected to bear seed, should be emasculated at an early period of their existence, that is, the anthers should be carefully removed, and in the case of some species, it is necessary to do this even before the blooms have expanded, in order to prevent the possibility of self-fertilisation; in the case of some small flowering species, however, there is some difficulty in effecting this, although it is easy enough to accomplish it, in the case of such plants as the Petunia, &c., by merely slitting a small portion of the tube of the corolla, and removing the unripened anthers, taking care at the same time to avoid injuring the stigma, which should be afterwards carefully watched; its slightly glutinous condition, will indicate its readiness for the application of foreign pollen, which should be carefully applied with a camel-hair pencil or otherwise. Roses which were budded in June or during the early part of July ought now to be looked to; the ligatures used to secure the buds in their places, should be loosened, to prevent the flow of sap being in any way impeded, and to admit of the natural expansion of the shoots and young buds; while buds which may have been inserted somewhat late last autumn or grafts put on last spring will, in most instances, have made strong shoots, and will require support in the form of stakes to prevent them from being blown off by high winds or from breaking down by their own weight when wet. The clipping and cutting in of Yew and other hedges connected with the pleasure grounds and parterres should now be proceeded with as rapidly as possible; although, on account of the long drought which has been experienced during the present season, there will possibly be much less to remove than is usual. Cuttings of all sorts of bedding Pelargoniums should now be inserted without further delay wherever they are to be obtained. In many instances, however, it is to be feared that they cannot, as yet, be taken from the beds in the flower garden without injuring them; but, where there is a well-stocked reserve garden, cuttings of all sorts may be taken from that department without fear of disfigurement. They may be inserted in the open border in lines or otherwise, and may remain in that condition until the beginning of October, when they should be lifted, potted singly, and placed under glass, or they may be inserted four together in 4-inch pots, and placed on cinder ashes in the open air.—P. GRIEVE, *Colford Gardens, Bury St. Edmunds.*

Roses.

Briar stocks will require more attention than usual this season to get the lateral shoots to grow strong enough for budding; all laterals,

except two or three at the top of the Briar, should be cut away, and all root suckers should be removed at once. I find that a slight mulching of leaf-mould, old tan, or of any decomposed garden refuse, keeps the ground among Rose Stocks from cracking, and also helps to retain moisture, whereby lateral growth is much benefited; this season's Stocks should have a good watering two or three times a day, before they are budded, an operation which will cause the bark to rise more freely than it otherwise would do. If the bark does not rise well it is of no use to bud, but, on the other hand, budding must not be deferred until the bark gets set. July and August are the two best months for budding, and our finest show blooms the following spring are cut from Roses budded in the autumn. In budding, select the best and most prominent-looking buds for the purpose; those from the middle of the shoot are best; the top ones are often too soft, and the bottom ones are not sufficiently developed and often lie dormant; the bud should be cut clean out and the heel should not be more than $\frac{1}{4}$ of an inch long; make an incision with the budding knife in the form of a T about 1 inch long, on the base of the lateral shoots, carefully raise the bark and then insert the bud, taking care to get the heel close down to the stock; then make all secure by tying with soft wool or matting. The following six varieties worked on strong Briars, if kept well trained, make excellent umbrella and pyramidal trees, viz.:—Gloire de Dijon, Climbing Devonensis, Anna Alexieff, Jules Margottin, Duke of Edinburgh, and Princess Mary of Cambridge. Of these, the two first are Teas, the rest hybrid perpetuals.—H. G.

Indoor Plant Department.

Attend to the training of climbing plants, or they soon get a confused mass. Keep a diligent look-out for insects of all kinds, for they increase with the temperature of the season, and if left even for a time entail much more labour and do a great amount of injury. Give now a little more air, less shade, and give less water at the root, as well as in the atmosphere. This will assist the season's growth to ripen; but do not reduce the temperature of the stove, as we see frequently done, until the ripening process is complete, that is, the wood well matured and hard. Plants that are prematurely put to rest by the unnatural method of reducing the temperature before the growth is ripened, are almost certain to start into growth when not wanted, during the application of the extra heat required during severe winter weather; in which case it is useless to expect a satisfactory amount of bloom. Allamandas, grown in pots with the intention of training them on wire or wooden trellises, should have their branches allowed to grow loosely upright, until they are either opening their first flower buds, or nearly so; as, if trained down as they make their growth, they never bloom so satisfactorily, as when the point of the shoot is brought down lower than the head of the plant; the first effort the plant makes is to adjust the balance of the sap, so rudely disturbed by pushing the eyes of the shoots that are bent over the top of the trellis, and so starves the points of the shoots from which the bloom ought to proceed; and this holds good of all plants of a similar character. Numbers of seedling Ferns of some varieties will make their appearance—such as Adiantums, Lomarias, Davallias, Dicksonias, and these, if carefully taken up without materially injuring their roots, and potted in small pots, after which kept a little close until they get established, will be found very useful, either for standing amongst the larger plants, filling Fern-cases, or for decoration in other places apart from the Fern-house proper. All the stock should be gone over repeatedly, during the season of growth, with brush and sponge, in order to remove any insects that will now thrive apace with the warmth of the season, and which, if left to themselves, even for a comparatively short time, entail a great amount of labour, and spoil the appearance of the plants. Continue to encourage the growth of Azaleas by closing the house early—say by four o'clock, syringing well overhead, and by throwing an abundance of water about the paths and floors of the house. It should be borne in mind that these are hill-region plants, and that, in a state of nature, they grow in a moist atmosphere, different from what they often receive under cultivation, where we see them making their young growth with small sickly foliage. Azaleas are plants not easily killed, and consequently exist for years under such treatment, but they bear no comparison with plants well-grown. Some hard-wooded plants will now have completed their growth, and may be placed in a sheltered place out of doors, where they will get a moderate amount of sunshine, which will harden their growth and help them to get through the dull autumn and winter months without the attacks of that certain visitant to unripe foliage—mildew. The stock should be gone over twice a day in bright weather to see that nothing suffers from want of water. Encourage Heaths, but especially the summer-flowering kinds, to make their growth. In case of such as have almost completed it move them out

of doors, where they will receive all the light and air possible; but guard the pots from the full action of the sun, otherwise the roots may suffer, more especially such pots as are well filled with roots. They ought to stand on 6 inches of ashes to exclude worms, and if there are no means at hand to protect them from drenching rains, they should be laid down on one side during heavy rainfall. This will keep the roots from being saturated with wet.

Orchids.

Give less moisture both at the root and in the atmosphere to such pseudo-bulbous species as have finished their season's growth and seem inclined to rest. It is, however, impossible to lay down general rules as to the watering of Orchids, the most successful cultivators being those who treat every individual plant according to its requirements. Orchids come from so many different climes, and their seasons of growth and rest are so variable, that all one can do is to assist Nature instead of thwarting her, when all will be well. Pleiones which have finished their growth should have a few weeks rest, and preparations should be made to re-pot them as soon as the blooming season is over, for like most other *Cyclogynes*, their flowers and young growth are produced simultaneously. *Odontoglossums*, *Cypripediums*, and cool growing Orchids, as *O. macranthum*, *O. serratum*, *O. zebrium*, and *O. obryzatum*, will require copious supplies of water at the roots. *Masdevallias* will, in many cases, be making new growth, and should have as much light as possible, and copious supplies of moisture at the root. If the *Sphagnum* on the top of the pot is not in a fresh and growing condition, it should be at once renewed. Living *Sphagnum* Moss is indispensable to the Orchid grower, and if it keeps fresh and green it is one of the surest signs that the temperature is sufficiently genial, and that the atmosphere is charged with enough humidity to suit most kinds of Orchidaceous plants. Plants in flower, such as *Odontoglossum Alexandræ*, *O. Schlieperianum*, *O. vexillarium*, *O. Roezii*, *Masdevallias*, *Oncids*, *Miltonias*, *Cattleyas*, and *Trichopiliass*, may be removed to the conservatory, where, however, a little fire-heat will be essential on cold and wet nights, otherwise, the flowers will suffer from an excess of moisture and decay prematurely.—F. W. BURIDGE.

Hardy Fruit.

It may seem late to many to give the advice to finally thin all stone and other fruit to a medium crop; but, it is not yet too late. Late Peaches, Nectarines, Plums, &c., are never safe until thoroughly stoned; even in the finishing process they often cast a good many fruit, and, therefore, it is safer to leave reserves until the stoning is completed. There is something analogous to stoning in the growth of the seeds of Apples and Pears; a good many fruits often fall just as they are about to take their second or final swelling. When these are off, all excess should be removed, and, in all cases of fruit thinning, the worst shaped and worst placed, should, of course, be taken. In thinning Pears, not only cracked fruits, but those that have a tendency to crack, should likewise be picked off. The severe thinning of fruits not only improves the quality and size of those left, but adds to the health and strength of the trees. By thinning early we probably divert the vital forces that would have gone to develop those removed into those that remain. In late thinning we probably fail thus to divert the strength meant for one fruit into another; but, the act is useful, nevertheless. The entire tree gains by the husbanding of its force, and each fruit left shares in the greater plenty provided by the enhanced strength of the tree. The late showers have been very beneficial to fruit trees, and, indeed, for all wall trees, nothing is more useful than a daily artificial shower over head in the afternoon and evening of every hot day. These showers refresh the leaves, and develop the fruit to a fuller size than it otherwise would be. No practice tells more on the size and quality of Peaches than this daily overhead sprinkling, up to, say, within a fortnight of their maturity. It is, in fact, as much or more needed in August than in any month of the year. It is death to spider and most other insect pests, and gives new life and greater vigour to the entire tree, root, leaf, and branch. Protect, as much as possible, ripe fruit and fruit ripening from the attacks of insects. Hollow stems of umbelliferous plants, or short lengths of large reeds, are the best traps for earwigs and woodlice, and if a drop of sugar and water is sent into them, also for ants—the most destructive of all. These should be placed with one end under a branch near to the fruit and emptied into boiling water every morning. Wasps have hardly appeared yet, but, as soon as the first is seen, hang wasp bottles, baited with beer, against the walls; these are so effective for wasps that the bottles will require emptying every morning, and wasps may be destroyed in such a way as must tell against these greedy hosts. Wasp nests must also be sought for, discovered, and totally destroyed by being suffocated with a fusée of sulphur and gunpowder, or, simpler still, a rag or

piece of cotton-wool dipped in turpentine or carholie acid. A pint of tar poured into the hole is also a disabler, and a final—though slow and cruel—mode of destruction. Birds can be netted off, but we cannot master these smaller insects unless by destroying them, and to have perfect fruit, we must see to their prompt destruction. Apricots and all other fruits should be gathered the moment they are ripe, and no fruit be allowed to decay on the walls nor in the garden.—D. T. FISH.

Kitchen Garden.

Spring Cauliflowers are an important crop in most places, and require a considerable amount of attention for a long period in order to secure a satisfactory result. The time of sowing has great influence upon the future crop turning out satisfactory or otherwise, for if sown too early—and a very few days will sometimes make an important difference—many of the plants may button or turn in prematurely, and thus be useless. To obviate this difficulty wherever it may have been felt, it will be better to divide the seeds into three portions and make three sowings, at about a week or ten days intervals. In the north, the first sowing should be made about the 10th of this month; in the midlands, about the 15th; and in the south, from the 20th to the 25th; and, the last sowing, at least, should be made in a frame. In cold late situations I have always found it the best and surest plan to delay sowing till about the middle of September, and to sow in boxes in a frame; but, after the seedlings have come up, in order to have sturdy little plants, abundance of air should be given. In January, a sufficient number for forcing, or for hand-lights, should be potted into 60-sized pots, and placed in any warm house or pit near the glass, where a free ventilation can be had in favourable weather. In about a month they should be taken to a cold frame and hardened off previously to planting them out under hand-lights or in any warm situation. A few of the strongest may be potted on into 8-inch pots for forcing in pots. With liberal surface dressings and free applications of liquid-manure very good Cauliflowers may be obtained early in this way. Of course, all this implies that there is sufficient space under glass for this purpose; and, where this can be obtained, Cauliflowers will force as easily as Potatoes or any other vegetables. Between this and the middle of the month is a very good time to make the last sowing of Turnips for use in spring; in fact, in the north this should have been already done. For this purpose I sow the Chirk Castle Black Stone; it is very hardy, and displays a less tendency to "bolt" in a mild spring than any other Turnip with which I am acquainted. Have the Mushroom-house thoroughly cleaned out and the walls white-washed, pouring boiling water into all cracks and crevices to destroy woodlice, &c., so as to start the autumn and winter beds next month in a house free from insect pests. There will probably be plenty of Mushrooms in old pastures from this time till October, if we have sufficient rainfall to moisten the ground. A warm summer if followed by a dripping autumn is usually very productive of Mushrooms. In sowing Lettuce at this season the Bath Cos must not be forgotten, as, from its compact growth, it is easily lifted when full grown and placed under cover in bad weather. The Tom Thumb Cabbage Lettuce should also be sown in quantity. Sow in an open situation. As the days are now rapidly shortening, and the sun losing its power and wherever there is not sufficient moisture in the land to cause the seeds to germinate, it will be better to water the bed thoroughly before sowing, and afterwards shade with branches, rather than water after the seeds are sown.—E. HORDAY.

Cottagers' Gardens.

The season for sowing some of the most useful garden crops is now drawing near, and, if possible, ground should be selected for them that has been dug up some considerable time; for if very dry soil is dug up and crapped immediately, it will be almost impossible to find moisture enough for seeds to germinate in it. The principal sowing of Cabbage should be made at once; Onions of the Tripoli or Giant Rocca kinds should be sown partly at the middle and partly at the end of the month; sown at these times they succeed better with us than spring sown Onions, especially those transplanted from late sowings. Turnips succeed well after early Potatoes, which may now be lifted. Vegetable Marrows and Cucumbers will now be bearing freely, and should receive constant attention in the way of thinning both shoots and foliage; the fruit should be cut directly it is fit for use. Scarlet Runners should receive liberal supplies of water; planted in patches by the sides of walks or against fences, they form one of the most ornamental as well as useful crops in the garden. Herbs should now be dried and stored away in an open shed for winter use; the old plants will yet have time to make a good growth before winter. As regards plants (such as Stocks and Wallflowers) they may be transplanted, and Polyanthus and Primroses may be divided.—JAMES GROOM.

HOW WE ACQUIRED A TASTE FOR FLOWERS.

"WELL I think I can tell you how we all came to be so fond of flowers, and to be able to grow them, and a few vegetables also." The speaker was apparently a well-to-do mechanic, neat and tidy in his appearance, and with a greater look of intelligence and refinement in his countenance than is common among people of his class; his auditors were strangers from a distant part of the country, to whom the pretty, tasteful, and well-cultivated gardens attached to the cottages about them were evidently novelties. "You see, when I was a young man and just out of my apprenticeship, there was a great to-do in this city of ours among what were called the working classes—just as if many a man who never soils his hands has not to work hard with his head sometimes—about shorter hours, higher wages, and so on. I daresay the masters and men had each some cause to complain of each other, but I am not going to enter into their quarrels and battles; I only say, that after years of bother, matters were arranged on a basis apparently satisfactory to both parties. When that was the case, the men had a deal more money to spend, and more time in which to spend it, than they ever had before. Few suitable means of getting rid of this time and money were available to them. Their faculties were not trained so as to enable them to enjoy the various museums and other interesting institutions which were open to them; and these, although professedly free to all, were in general hedged round with many irksome rules and regulations, rendering them distasteful to the very classes they were intended to benefit. In short, they did not, for one reason or other, take advantage of the means of improvement at their disposal. Instead, then, of attempting to ameliorate their condition by mental cultivation, the majority of men, after their day's work was over, spent their evenings in drink-shops and singing saloons, to the great profit of the publicans and the benefit of the revenue; but a few, of whom I was one, used to take good long walks into the country, thereby enjoying the pure air, and the many and beautiful objects which Nature so liberally provides for the benefit of every one. In some of our rambles we had often to pass nursery gardens, which always stood temptingly open, as if inviting us to enter and inspect them. When we had summoned up courage enough to go inside, we found no one to interfere with us, and we were welcome to wander about just as we pleased, and to see whatever was to be seen. If at any time we made any inquiries of the workmen, they answered them with civility, and appeared anxious to impart any information which was in their power, and by so doing interested several of us so much about flowers, that we resolved, on the first opportunity we had, to visit the Botanic Gardens, where we hoped to learn much that we could not do in the nurseries, as we were unreasonable enough to suppose that, as those gardens were for the public benefit, there would be some properly qualified officials there to enlighten the ignorance of the visitors. The Botanic Gardens were very fine then, but not nearly so much as they are now. In those days the entrance to them was only by a paltry little door in a high dead-wall, evidently intended to prevent the interior arrangements being seen by passers-by, and reminding one far more of the entrance to a lunatic asylum or penitentiary than a place for recreation. On ringing a bell an attendant appeared and opened the door just wide enough to admit us. He cast rather a suspicious glance at us, and evidently thought it very hard to have been put to the trouble of opening the door for us. I remember that over the door there was a notice about the hours when the gardens were open and when shut to the public, and part of it was that from six till eight on Saturday evenings during summer they were open for the benefit of the working classes. None of us could at all make out why only one evening of the week was allowed for this very large section of the community, as every other night as well as Saturday could be made available by some portion of it, especially now that the short-time movement was fairly inaugurated. Whatever idea the authorities might have intended, we took the notice as a sort of hint that the working classes' company could be dispensed with at all other times; and we could not help thinking how much better it would be were the gardens open every evening till sundown, so that all classes whatsoever might come with their children, whose school hours would be over, to enjoy the many pleasant sights to be seen within the walls.

"This first visit of mine was, however, the means of giving me a new interest in life, for which I have ever since been very thankful; and I fancy that, from what I then saw and heard, I have been useful in increasing the happiness and comfort of many of my fellow workmen. Whilst walking through the conservatories, Palm-houses, &c., feasting our eyes on all the beauties they contained, we happened to overtake a party of jolly, good-natured looking sailors, who were evidently well pleased to see growing here many plants, trees, and flowers with which they had formed a kind of acquaintance during their wanderings about the world, but apparently thought little of them here when compared with the specimens they had seen abroad,

and were quite as much bewildered as we were at the prodigiously long names that some of the things were labelled with. 'Why, look ye here,' said one them to his companions, 'whatever do they give this little chap—not big enough to make a thole-pin for the dingy—a name as long as the mainto'-bowline for?' Should any one remark to me that such-and-such a thing was as big as a lump of chalk, or as long as a bit of string, I would at once know what he meant, because everybody knows what they are; but to my mind the mainto'-bowline was only an embodiment of a straight line, length without breadth or thickness, and as I wanted to know something more about it, I asked the sailor what it was. Instead of answering me, he only stared at me for a while with the greatest amazement, and turning to his shipmates, said; 'Well, boys, longshore folk call us ignorant, but did any mortal man ever see a fellow on board come to that one's time o' life who didn't know what the mainto'-bowline was! Why, I expect he wouldn't know the best bower from the cook's tormentors, were he to see them together. But, I say, what's the use of staying in here, looking at these things; we see enough of them when we're away from home. Let's go outside, and have a roll on the Grass, for we can't see a bit of turf like that except in the old country.' So commiserating my ignorance, they left me to have their roll on the nice velvety turf, whilst I staid behind, pitying the taste of anyone who would prefer a patch of Grass to contemplating the beauty of the exotics. I strolled away from my companions, and found the very commonest flowers with names I could not understand; but pondering on the subject, I saw that owing to the enormous multiplicity and variety of plants, some accurately distinct appellations common to all countries were necessary. It was rather painful to see so few people taking anything like an intelligent interest in the plants set out for their instruction. The most of them only admired the flowers. In the fine shady walks, ladies and gentlemen, generally young, were seen lounging along in pairs; the lady intently examining the toes of her boots, and poking holes in the gravel-walks with the point of her parasol; and the gentleman quite as intently examining the lady's ear, or perhaps watching her curls—they used to be worn in those days—and both seemingly much at a loss for anything to say to each other. The gardens, in fact, were more a lounge for idlers than anything else. Perhaps the sight of so many plants, native and foreign, in time works a revolution in the feelings. In my own case, I felt no small enjoyment in my rambles. My mind was, as it were, opening on a new world of rational pleasure. As often as I possibly could, I returned for a walk in the gardens, and always brought some of my companions with me, till at last quite a large number of young men and women began to take an interest in flowers, and to entertain a desire to obtain information about them. So we got an obliging young gardener to come when his work was over, and tell us as much as he knew about the plants and flowers. By-and-bye this gathering became a regular class; and it was soon observable that those who attended it began to show a great deal more taste and neatness, not only in their dress, but in their general household arrangements, than they did before. Here, then, was the beginning of a social reformation, all arising from the habit of looking at plants and flowers. The authorities saw this, and appointed a gentleman to give popular lectures on the vegetable kingdom. The Latin and Greek names were translated into English equivalents, and although they still continued of a considerable length, they were in a language we all knew, and they, therefore, conveyed some meaning to our minds, and were more easily remembered. These lectures were largely attended, and the gardens came to be so very much frequented, that they were kept open till sunset every day, and the blank-wall was pulled down, and replaced by the fine open railing and ever-open gate which is there now, affording a refreshing peep to all who are passing. About the same time, too, the magistracy of the city was busy pulling down the old lanes and closes with which it abounded, and letting more air in about it; and some speculators, finding so many people taking to gardening, built cottages in the suburbs, where they could have bits of garden-ground attached to them. Then the people who took those cottages discovered that they wanted to know something about vegetables as well as about flowers, and, by dint of determination, got a suitable portion of the garden set apart where the best sorts could be grown, and where people could be taught the best modes of growing them. Such I believe to be the reason why so many men in and about our city have gardens, and know how to cultivate them; and how their wives, seeing them take so much pride in their outdoor neatness and decoration, and vegetables, soon learned to keep all indoors neat and tidy, and to have the well-grown vegetables well cooked. In consequence, also, of this taste for horticulture, the men had to consult books on the subject, and soon had little libraries. But reading gardening-books led them into reading about other subjects, and you will now see in almost every cottage a few shelves of well-selected works by the most intelligible

authors in almost every department of science. What a grand future would open on the condition of the manual labouring classes generally, were they simply to begin to take an interest in flowers! With improved tastes all else would follow. Even now, in some places we are favoured with a glimpse of that greatly to be desired future."—*Chambers' Journal*.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

August 5th.

THE most remarkable features of this meeting were the new Orchids and other plants staged by Messrs. Veitch and Mr. W. Bull; Mr. G. F. Wilson, Mr. Barr, and others, also furnished splendid plants and cut spikes of Lilies, chiefly of the *L. auratum*, *L. speciosum*, *L. Thaubergianum*, and umbellatum types. Two splendid smooth Cayenne Pines, weighing 9 lbs. each, came from the Royal Gardens, Frogmore.

Orchids.—Messrs. Veitch & Sons exhibited several hybrid Lady-slippers, including *Cypripedium Sedeni*, *C. Harrisianum*, and *C. Dominionum*, all of which are now recognised as valuable additions to the genus to which they belong. A remarkably healthy plant of the bright purple-flowered *Aerides Huttonii* bore a spike of flowers nearly 2 feet in length; this plant is very distinct from any other species of the genus in cultivation, and, evidently, improves under good culture; a plant of *Saccolabium Blumei* majus bore four fine wreath-like spikes of pearly-white lilac-tipped flowers, and a species of *Stanhopaea*, something in the way of *S. oculata*, also bore a seven or eight flowered spike of yellow flowers, profusely spotted with brown. In addition to these the collection included a fine specimen of *Masdevallia Veitchii* with four spikes, *Aerides suavisimum*, the deep claret-purple flowered *Miltonia Morelliana*, and others. Mr. Bull had a plant of the snowy-white *Cypripedium niveum*, *Odontoglossum Roezlii*, and a healthy specimen plant of *Lolia elegans Andersonii*, bearing a splendid spike of deep rosy flowers, the lip having pure white lateral lobes, and a rich crimson-purple central one; it is one of the best and most distinct of all the forms of this well-known Orchid. Mr. Denning exhibited a cut flowering pseudo-bulb of an unnamed *Dendrobium* bearing dense clusters of vivid orange-yellow flowers; in habit, the plant seems to be near *D. secundum*, but the flower-spikes are more copiously produced, the bulb shown being perfectly wreathed with flowers; the sepals, petals, and lip, are conspicuously striped with reddish-brown, and the plant is certainly worth cultivation as one of the most distinct species hitherto added to our collections.

New Plants.—Of these Mr. W. Bull had a fine group. Conspicuous among them was the ivory-veined *Arad*, *Phyllatanum Lindenii*, with great halberd-shaped foliage; *Dracæna Shepherdii*, one of the most robust of all the species; *Croton spirale*, well coloured; *C. majesticum*, *C. volutum*, and others. Some of the *Cycads* in this group were very ornamental. *Macrozamia plumosa* is one of the freshest and most graceful of all the species, the leaflets being a foot long and very slender, drooping elegantly on all sides.

Roses.—Messrs. Geo. Paul & Son, of the Cheshunt Nurseries, staged eight stands of cut Roses, many of the flowers being in fine condition. Among these we may note *Louis Van Houtte*, a fine velvety flower; *S. Reynolds Hole*, something in the same way, but much darker in colour; *Gloire de Dijon* and *Madame Villermoz*, both good; *Camille Bernardin*, an old favourite, of a pale rosy-crimson colour; and *Ladla*, a large flower, of the most delicate rosy-flesh; *Baronne Rothschild*, one of the very best of light exhibition kinds; *Ettiène Levet*, a deep rosy-crimson; *Madame Baumann*, and others.

Miscellaneous.—Mr. R. P. Barr staged a fine collection of cut Lilies, among which we noticed *L. tigrinum fl. pl.*, a double form well worth a place in all collections, the white-flowered *L. longiflorum*, and others of the umbellatum type. Mr. H. Loder, gardener to H. P. Hennell, Esq., Mayo Road, Forest Hill, sent a splendid specimen of *Lilium auratum* with two stems, each about 10 feet in height; the larger of the two stems was fasciated towards the top, and bore the enormous number of forty-eight flowers, while the smaller one bore seventeen. The plant was well clothed with healthy foliage to within 18 inches of the top, and deserves mention as an example of what this plant is capable of becoming under superior cultivation. Mr. Offord, of Upper Clapton, sent *Ageratum*, Clapton Gem, a dwarf and tolerably free-flowering form of *A. mexicanum*. Mr. Woodbridge sent fine cut sprays of *Clethra arborea*, a beautiful half-hardy evergreen shrub, bearing terminal panicles of pearly white flowers in great abundance; also *Pavia macrostachya*, with deep green lobed leaves and slender terminal spikes of white flowers with long stamens and crimson anthers; *Hibiscus syriacus*, and both rosy and white varieties of *Ceanothus americana*. Mr. Stanton, Silk Mills, Lewisham, sent two seedling *Lobelias* of fair average merit, and Mr. Eckford sent cut trusses of *Verbena*. Mr. R. Dean sent stands of French and African Marigold flowers, very double and bright in colour, also fine blooms of Camellia-flowered Balsams. Messrs. F. and A. Smith sent a fine group of Balsams, with large and richly coloured flowers. The plants were sturdy and dwarf, the colours being both variable and distinct. It seems a pity so useful a decorative plant and one which everyone can grow, either out of doors or as a window plant, should not be more generally cultivated.

Fruit and Vegetables.—These were limited in quantity, although some specimens of both were above average merit. Mr. R. Dean sent

two fine dishes of Potatoes from Bedford. One variety was a large white Kidney, raised by Mr. Robert Fenn, of Woodstock, and the other, Snowflake, a fine American variety of more than average merit. The same exhibitor also sent a dish of Exhibition Runner Bean, evidently a good form of the old Scarlet Runner, and a hardy frame Cucumber, named Green Gem, on account of its fresh colour. It is said to have an excellent constitution, and to be a prolific bearer during the summer months, succeeding well as a winter-fruited variety treated in the usual way. Mr. Morris sent two dishes of a new seedling Potato, not named. Messrs. Barr & Sugden sent fruit of Marquis of Lorne, Duke of Edinburgh, and Laton Hood Cucumbers for comparison. Mr. Woodbridge furnished a small collection of Plums; Mr. Sage excellent fruit of Walborton Admirable Peach; and Mr. J. Clark, Roehampton, an excellent dish of Moor Park Apricot.

First-class Certificates were awarded to the following novelties:—

Metroxylon filare (Bull).—An elegant Palm, belonging to the pinnate-leaved section, and having gracefully recurved leaflets, the leaf-stalks being rather formidably armed with extremely slender brown spines. It is a useful addition to the genus to which it belongs.

Zygopetalum, seedling (Veitch).—This plant resembles *Z. Mackayii* in habit, the sepals and petals being dark brown, with a bluish-purple lip, and the curiously plaited crest peculiar to the group. It is a very interesting addition to a useful and well-known group of showy-flowered Orchids.

Lilium speciosum atro-sanguineum rubrum (Wilson).—This is an extremely fine and early-flowering form of the common Japanese Lily, the individual flowers being 8 to 9 inches across, and very richly coloured, while the plant itself is robust, and scarcely exceeds 2 feet in height.

Dendrobium, species (Denning).—This is a beautiful and free-flowering addition to a division of the genus, not remarkable for conspicuous-flowered species. It may be likened to *D. secundum*, but flowers more profusely, bearing orange-yellow flowers, with segments striped with brown.

Fuchsia procumbens (Kingham).—A Botanical Certificate was awarded to this graceful New Zealand species, which has recently been raised from seed, and flowered in several collections. It is not showy, but possesses a graceful habit, and may be useful to hybridisers.

The New Approach to the Thames Embankment.—The block plan of the proposed new approach, recently laid before the Metropolitan Board of Works, shows a road 90 feet wide, which is nearly the same width as the Embankment roadway itself. Much discussion has taken place as to the width of the street, it having been contended that such a street in such a situation could hardly be made too wide, the only doubt being whether it ought not to be 100 feet in width.

The Timber of the United States.—Professor Brewer, of the Sheffield Scientific School of Yale College, has surprised the meteorologists of the old world, who have been led to believe that the climate of the United States has been gradually changing through the destruction of its forests. He has written a letter, in which he shows by figures that no such destruction has been going on, and if there has been any change of climate, it must be from some other cause. He says, that in the older settled portion of the Eastern States—New England and the Middle States—one third of the whole farming area is still woodland, and that if we extend our observations further to the south and west the facts are still more striking.

Predatory Chickens.—Try Max Adler's method, which he describes as follows:—"We had a good deal of trouble last summer with Pitman's chickens; as fast as we planted anything in our little garden, those chickens of Pitman's would creep through the fence, scratch out the seed, fill up, and go home. When the Radish-bed had been ravished in this manner for the fifth time, we complained to Pitman. He was not disposed to interfere. 'Adler,' he said, 'I tell you it does 'em good; and it does them beds good to be raked over by chickens. If I had Radishes, give me chickens to scratch around them and eat up the worms. Radishes that haven't been scratched ain't worth a cent.' Then we climbed over the fence with the determination to take the law in our own hands. We procured half-a-peck of corn and two dozen small fish-hooks. Fastening the hooks each to a grain of corn, we tied wire to each hook. Then we scattered the whole of the corn on the Radish-bed, and fixed the ends of the wires to the biggest sky-rocket we could get. The rocket stood in a frame about 10 yards away from the hooks. That very morning Pitman's chickens came over, and instantly began to devour the corn. We were ready; and, as soon as it was evident that the hooks were all swallowed, we applied a match to the rocket. It is regarded as probable that no barn-yard fowls that have existed since the days of Noah, ever proceeded toward the azure vault of heaven with such rapidity as those did. A fizz, a few ejaculatory cackles, a puff of smoke, and Pitman's roosters and chickens were swishing around among the celestial constellations without their feathers, and in some doubt respecting the stability of earthly things. Pitman never knew what became of his fowls; but, when we read in the paper next day that twenty-four underdone chickens, with fish-hooks in their craws, had been rained down by a hurricane in New Jersey, we felt certain that that sky-rocket had done its duty."

THE GARDEN.

"This is an art

Which does mend nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

HARDY ERICACEOUS PLANTS.

By JAMES M'NAB, Royal Botanic Gardens, Edinburgh.

No class of shrubby plants now in cultivation is, perhaps, more interesting or better adapted for rock garden purposes than the hardy dwarf Ericaceous group, such as the species of *Menziesia*, *Daboecia*, *Ledum*, *Cassiope*, *Andromeda*, *Vaccinium*, *Erica*, *Calluna*, also *Azalea procumbens*, *Arctostaphylos alpinus*, *Bryanthus erectus*, and *Rhodothamnus chamaecistus*, &c. They are mostly kinds which naturally grow in high and dry situations, and stand with impunity a considerable amount of drought, as has been sufficiently tested during the past summer, more particularly when they become thoroughly established in rock garden compartments, or between the crevices of the stones comprising them. When an Ericaceous rockery is to be formed, the ground selected ought, if possible, to slope towards the north, or should be placed behind a south wall, in order to avoid full exposure to the sun, where such plants would be apt to dry up, besides requiring more artificial watering, which is apt to prove injurious to their leaves during a period of bright sunshine. If the rockery for such plants has to be constructed on comparatively level ground, the soil laid down for the purpose should be blocked into shape according to the taste of the operator, but made to slope towards the north. The south slope can be arranged irregularly, and afterwards planted with common or hybrid *Rhododendrons* interspersed with portions of Grass lawn. When the north or rock-garden slope has been worked into the outline wanted, which can be done with any kind of soil, the upper surface can be mixed with rough peat partially intermixed with broken pieces of sandstone free of iron, say from half-an-inch to 2 inches in diameter. The stones to be used for forming the plant-boxes of the rock-work must be about 16 or 18 inches long, and not less than 2 inches thick, also of a porous nature, and each placed about two-thirds into the soil, forming compartments from 6 to 12 inches in diameter, these spaces to be filled with chopped peat and broken stones. If the rock-work slopes much, which is highly desirable, it ought to be arranged, if possible, to show irregular artificial quarries, by dipping here and there into the ground. It is of importance, while planting the boxes, to have the surface-soil of the back portions of each compartment a little lower than the front, so as to enable the water, either natural or artificial, to sink down behind the plant, instead of running off, as it is apt to do, when sloping to the front. By this simple arrangement the moisture is not lost, and the stones being kept much longer moist, the roots will be found to adhere more firmly to them. All the Ericaceous, and the allied orders of plants, possess variety sufficient to fill a rock-garden of themselves, and varieties can be had and planted in duplicate to keep up a succession in a blooming state in the various compartments more or less all the year round. For the summit or highest portions of the rock-garden, compact plants of *Rhododendron hirsutum* and *R. ferrugineum* are admirably adapted, and, in such situations, mature their flower-buds well—often more profusely than they do in ordinary peat borders, where they may grow more vigorously, but produce flower-buds less abundantly. Such plants as *Menziesia empetriformis*, *M. Drummondii*, and *M. cærulea* are also well suited for rock-garden culture, and flower profusely every year. An occasional surfacing of fresh peat and sand will be found well adapted for such plants, particularly after the flowering is over, and before the young growths begin to form. The *Menziesia cærulea* seeds abundantly in such places; but, with the exception of one or two required for seed-bearing purposes, the flowers of all the others should be clipped off with a pair of scissors, so as to induce a free growth for the flowering of the following year. *Cassiope tetragona* and *C. fastigiata* are interesting objects for rock-garden cultivation, and flower profusely. Like the *Menziesias*, they are improved by having a little sifted

peat mixed with sand put amongst their stems; they will root into it, and their appearance will be improved for the following year. The *Daboecias*, white, purple, and variegated, are also very suitable rock plants. With the exception of the compact-growing varieties, all others must be clipped in after the flowering is over; they are likewise improved by having a little fresh soil placed amongst their stems; it will induce fresh roots, and the plants will be greatly benefited by it, instead of appearing long and lanky, as they are frequently seen. All hardy Heaths, such as *Erica Tetralix*, *E. cinerea*, *ciliaris*, herbacea, *Mackayana*, *Watsonii*, *vagans*, as well as numerous varieties of Irish Heaths of the *E. mediterranea* breed, likewise the many forms and varieties of the Common Ling, *Calluna vulgaris*, are all extremely well suited for rock-garden cultivation, and all are improved by being more or less clipped. This clipping is mostly done, immediately the flowering is past, with a pair of sheep shears, and if properly attended to in this respect, they will continue in a compact-flowering state for many years, while the want of it causes them to be long and wiry, and if allowed to get into this condition, any after-cutting will have a tendency more to destroy than improve, particularly if the weather should be dry and sunny after being done. As the varieties of the Ling Heath flower at different seasons, I generally find it best to clip each sort as soon as the blooming is over. Few of the hardy Heaths prove more effective for rock-garden decoration than the varieties of the Bell Heather (*Erica cinerea*). When rooted from cuttings, which all hardy Heaths ought to be (see THE GARDEN for 21st December, 1872), and placed between the crevices of rock-work stones, although not more than one inch apart, peat soil having been previously placed there, the plants root down, the branches spread, and flowers are freely produced in these limited spaces; this mode of treatment must be towards a northern aspect. *Azalea procumbens*, both Scotch and American, are well-suited for rock-work purposes, the soil for them must be well supplied with stones, so as to allow their long roots to get freely down between them. The *Arctostaphylos alpina* (Black Bear-berry) grows admirably in rock gardens; like the dwarf *Azaleas* and many others, it is better to have the surface of the compartment, after being planted, covered with pieces of freestone, which prevents the soil becoming too dry, but which cannot happen if the compartment has a northerly aspect, but if placed in a situation where they are likely to get dried, a slight covering of *Sphagnum Moss* placed over the surface of the soil in the compartment before the stones are put on, will prevent over-drying. *Gaultheria procumbens*, *G. carnea*, *G. prostrata*, and *G. nummularioides*, *Vaccinium Myrtillus*, and *V. macrocarpum*, *Epigaea repens*, *Rhododendron lapponicum*, *Andromeda hypnoides*, *Diapensia lapponica*, *Pyxidanthra barbulata*, all Ericaceous plants, with numerous other dwarf shrubby ones, although not of the same family, deserve a place in the Ericaceous rock-garden, and, as they are reared immediately under the eye, they can receive more attention than they generally get in low level beds or borders, where such rarities are generally planted, and where they often get smothered with Moss or *Marchantia*. Of the latter class may be mentioned the dwarf species of *Rubus*, such as *R. arcticus*, *R. Chamæmorus*, *Dryas Drummondii*, *D. octopetala*, and *D. integrifolia*, *Galax apylla*, *Polygala Chamæbuxus*, *Linnaea borealis*, both Scotch and American, as well as the varieties of *Empetrum*, *Pyrola*, and the dwarf Willows, as *Salix reticulata*, *S. lanata*, and *S. herbacea*, with many others not named here, when so cultivated, possess an interest infinitely greater than can possibly be derived by being reared in the ordinary way of low border cultivation. Most of the plants above enumerated, are now growing in the Ericaceous department of the rockery in the Edinburgh Botanic Garden, and, notwithstanding the dry summer, they have all stood well, flowering more or less abundantly, and possess infinitely greater charms for the general cultivator, than can possibly be derived from any other method of growing such plants. A good quality belonging to most of these plants is their evergreen character. An artistically arranged group of them in a rock-garden is full of beauty in mid-winter, even before the myriads of rosy buds of the spring flowering Heaths begin to open, and grouped along with silvery evergreen Alpine plants, the effect is all the more charming.

NOTES OF THE WEEK.

— MR. J. BOSWELL SYME, Balminto, Kirkcaldy, writes to us to say that he has some seeds of *Helleborus colchicus*, *guttatus*, &c., which he will be happy to distribute to anyone who cares to receive them. Early application must, however, be made as they should be sown at once. They will not vegetate if kept till spring.

— As will be seen by our advertising columns, a company has been formed to work Mr. Cowan's patent system of lime-kiln heating, of which we have spoken favourably on several occasions, and which is highly approved of by Mr. Bennett, of Hatfield, and other horticulturists, who have already given the plan a trial. We are glad to see that Mr. Cowan holds the position of managing director.

— We have received from Messrs. Teutschel & Co., of Colchester, a bloom of a very handsome Lily, named *Lilium Thunbergianum anreum nigro-punctatum*. Its segments, which are of great substance, are golden-yellow, shading off into soft orange-yellow at the edges, and profusely spotted with chocolate. It is a showy and valuable addition to late flowering Lilies.

— At the Hale Farm Nurseries, Tottenham, the pretty little autumn-flowering bulb *Aeis* (*Leucojum*) *autumnalis* is now in bloom; as are also *Cypella Herberti*, a handsome Iridaceous plant with *Tigridia*-like flowers; *Chlora grandiflora*, a charming little bright yellow-blossomed Gentianaceous plant; *Echinacea* (*Rudbeckia*) *purpurea*; the brilliant scarlet *Pentstemon barbatus* *Torreyi*; *Erigeron glaucus*; and *Oenothera eximia* and *marginata*.

— On the recommendation of the Streets Committee, the Commissioners of Sewers for the City of London have passed an order to put Moorgate Street, Finsbury Pavement, Mansion House Street, and Queen Victoria Street under the permanent pipe system of watering of Messrs. Brown and Co., of India Buildings, Edinburgh. The three first mentioned thoroughfares are of asphalt, and the last mentioned of granite.

— ALMOST immediately the new road about to be made through the Green Park, in order to relieve the traffic from Piccadilly to the West End, will be begun. The new thoroughfare will lead out of Piccadilly, opposite Hamilton Place, and proceed through the park. Constitution Hill is not touched, but, on the contrary, remains intact, by the intended construction of an arch, under which heavy vehicles going eastward will pass, private carriages going by Grosvenor Place. The new road is to be 60 ft. wide, and will presumably be a macadamised thoroughfare.

— MR. J. LUCAS, of the Geological Survey of England, has just published a treatise "On Horizontal Wells," in which he asserts that he gives a "solution of the problem of supplying London with pure water." Examining the geology of the greensands and chalk of Surrey, he finds that above 1,000 feet of porous strata rests upon a bed of "absolutely impervious clay," and he contends that "a tunnel driven along the strike of the beds, or water-level, must of necessity arrest all the water that is flowing down it as far as the gallery is carried." The geological evidence given appears conclusive; we may, therefore, hope that a source for the supply of London with "the best and purest spring water" has been discovered.

— THOSE engaged in building extensive stone-gardens, making costly geometrical arrangements for fountains, and other purely artificial garden "adornments," will do well to ponder over the following note:—"At a meeting of the shareholders of the Crystal Palace Company, which took place the other day, Mr. Wakefield in the chair, to consider a plan for the restoration of the building, Mr. Scott Russell said that he had made an inspection of the Palace at the request of the Reconstruction Committee. The whole of the capital expended on the part of the building which had been burnt down, both upon the building itself and its valuable contents, had been lost through the culpable negligence of some one, and there had not been any attempt made to restore that part of the structure. There had also, he found, been an entire wing of the Palace blown down, and no effort had been made to restore that portion either. He found the whole of the grand cascade of the waterworks, which had cost nearly £300,000, going to ruin. The two cascades lower down were also going to decay, and so was the building opposite, in which used to be seated illustrious people who visited the Palace. A great number of the pipes and communications of the waterworks were likewise going to ruin. On looking into the state of the machinery of the waterworks he was astonished to find that the economical portions had been allowed to go utterly to ruin, while the most extravagant and costly part of the works, which were but seldom used, had been maintained in full working order. As to the courts of sculpture, Mr. Russell found that the works had nearly all gone—where, he could not tell. From some a finger, a nose, or an arm was missing, and, apparently, there had been no attempt to replace the missing parts of the statues.

The magnificent collection of art sculpture was in a most disgraceful condition. The works were in such a state of decay throughout, that a very large sum would have to be speedily expended upon the property.

— THE Torbay Nursery, Torquay, hitherto in the possession of Messrs. Morgan & Sons, has just been purchased by Mr. W. James Veitch, the eldest son of Mr. Robert Veitch, of Exeter.

— THE last published part of the Linnean Society's Transactions contains Mr. J. Scott's Notes on the Ferns of British Sikkim, with eighteen plates, and Prof. Reichenbach's Enumeration of the Orchids collected by the Rev. C. Parish, in Moulmein, with six plates.

— MR. JAS. ANDERSON, the well-known Orchid grower, the originator, and for many years manager, of the famous Meadowbank collection has now taken Meadowbank, with the view of converting it into an extensive nursery of indoor and hardy plants generally. Among these, Orchids will form an important feature.

— MR. JACKSON GILLBANKS writes to us to say that in West Cumberland Mushrooms are so plentiful in the fields that they appear as if spread with "lime," a result, doubtless, wrought by heavy showers having fallen lately nearly every day for a week together in that district.

— We have received from Mr. Young, of Godalming, cut branches of his beautiful Golden Chinese Juniper named *Juniperus chinensis aurea*, a variety which promises to be a most valuable addition to hardy ornamental Conifers. For grouping along with Yews, Portugal Laurels, and other sombre-tinted evergreens, where striking effects are so much wanted, its bright golden colour will render it invaluable.

— THE Board of Trade has received from the Secretary of State for Foreign Affairs a copy of a French law, promulgated on the 25th ult., instituting a prize of 300,000 francs (about £12,000), to which may be added subscriptions from other sources, for the discovery of an efficacious and economical means of destroying the *Phylloxera* or of preventing its ravages. A commission nominated by the Minister of Agriculture and Commerce will determine the condition of competition and the award of the prize.

— THE white variety of *Hydrangea paniculata*, now in flower in Mr. John Waterer's nursery at Bagshot, and which will continue blooming till November, seems likely to prove a valuable addition to late-flowering hardy shrubs. The tree form of *Hedera Ragneriana*, of which there are several plants in the same nursery, shows a very distinct habit and aspect, and will be useful for planting under the shade of trees, or as an isolated specimen on Grass. A new golden variegated form of *Juniperus chinensis* also seems likely to prove both useful and ornamental.

— ON Monday evening last a constable arrested a drunken man in the act of tearing up a bed of Geraniums in Hyde Park. He had uprooted no fewer than fifty-five before he was caught, and had spoiled a bed for the rest of the season. Brought before Mr. Newton, he could offer no defence, and he was severely punished by the infliction of a fine so heavy as to render it nearly certain that he will lie in prison for two months—the alternative penalty. It was stated in evidence that lately a great many plants have been missed, among them being specimens of choice varieties; and that we consider the worst symptom which the incident disclosed. Under such circumstances it is not surprising that the magistrate should declare, with emphasis, his fixed intention to impose no fines, but in future to inflict imprisonment. He hoped the fact would be made known far and wide. We readily welcome his resolve, and give publicity to his note of warning. The persons who steal flowers and plants are guilty of a delinquency which bears the stamp of meanness as well as crime. The public themselves can do a great deal in aid of the police by keeping a watch upon depredators.

— THE thirty-fifth anniversary meeting of the Royal Botanic Society of London was held last week in the Inner Circle, Regent's Park, Sir Walter Stirling in the chair. Mr. Sowerby, the secretary, read the annual report, from which it appeared that the number of new subscribers who had joined the society during the year, was in excess of that of last year, and also much above the average. The numerical strength of the society had been fully maintained. The exhibition of flowers and the evening *fete* had been most successful, and were gaining in popularity. The new range of greenhouses for the preservation of plants relating to the arts, manufactures, and domestic economy, commenced last year, had been completed at a considerable cost, and thus extended facilities had been offered to teachers, students, and others seeking information relating to the vegetable kingdom. Free admissions to study had been issued to twenty-six artists, 318 to professors and students, and 31,500 cut specimens distributed to them. Several improvements had been made in the gardens, and many new and interesting plants added to the collection. His Serene Highness the Duke of Teck was elected president for the year.

THE LIBRARY.

LANDSCAPE GARDENING "FOR PERPETUAL BEAUTY."*

"HE who aims high, aims well, though he hit not the mark as high as he aimed," is an oft quoted aphorism of one of our old divines, full of grand meaning and noble purpose. On perusing the early part of this most recent literary production on landscape gardening, with its high sounding title, embodying, as it does, beauty both past, present, and to come—in fact, "everlasting beauty;" it struck us that the foregoing aphorism would have been most happy in its application—clearly the aim of the writer was high—and equally clearly, does he fail to hit the point at which he aimed. Nay, more, as we progress through the volume, the feeling is, that the title of this work ought to have been not "perpetual beauty," but "beautiful for ever." Some years ago, we were called in professionally by an elderly gentleman of somewhat penurious proclivities, to solve the enigma as to how the arrangements of the grounds surrounding a new house were to be disposed of; we found our friend deep in the study of a dozen or more landscape gardening works, some ancient, some modern, all expensive; failing to realise out of one anything definite to suit his own particular case, he purchased another and so on, with a cumulative result, that in the end left him in a much more confused condition of mind than at starting. After glancing at the books, which, were in truth, a costly and a really valuable lot, we suggested that he should transfer them to his library-shelves, and accompany us round his garden, or rather round the site of his proposed garden, where we had no doubt a few hours would place us in a position to reduce the whole of his theoretical ideas to such practical data as would result in the preparation of the necessary plans, and the ultimate accomplishment of the work so as to render it, if not a perpetual beauty, at least an object of beauty, and for beautification, so long as it lasts. The perusal of the present work with its high sounding title, brought the foregoing little episode very pointedly to our recollection; had it then been in existence, it might well have formed the culminating volume in the series, as of all the works on landscape gardening, it has never been our misfortune to peruse one less practical, and less adapted to assist the amateur who essays to try his hand at the ornamental and picturesque improvements of his grounds. Why, then, should this be—why should the most recent emanation from the horticultural press in this line require such an unqualified verdict? Our author has had, at least, some practical experience, in addition to a practical training, and ought to have been able to give us something more consonant with that practice than is evinced in the work before us; we live in a practical age, why then preach high sounding platitudes reduced, every now and then, to a sort of multiplication table-like regularity, that to us appears to be thoroughly meaningless. Evidently, our author, or possibly our author's "learned friend," to whom he alludes in the preface, is an admirer of Ruskin, and so, indeed, are we. There is no English writer imbued with a more refined love for, or capability of, appreciating beauty than Ruskin, and, what is more, he possesses a power of language that enables him to convey those ideas clearly to his reader. In his "Stones of Venice," "Modern Painters," nay, indeed, in all his works, there occur passages replete with poetry and the highest moral sentiment combined, which a writer on landscape gardening might fitly take for the heading, subject, or text of each chapter of his book. The author's aim ought, however, to be, not to soar with Ruskin after, if we may so call it, a lame-winged fashion, but rather to remain on *terra firma*, which, indeed, he states it is "his glory to beautify," and reduce those grand thoughts and sentiments embodied in Ruskin's works to a practical form, whereby he may benefit himself, his profession, and mankind at large. Lest it might be thought that we are dealing too harshly with an author who, in his preface, pleads inexperience in authorship, we will give one or two quotations and leave our readers to judge for themselves. In his chapter on "Beauty and Comparison," he says:

—"The word 'comparison' is, perhaps, the best I can make use of in order to convey a sense of the general feeling which I desire to express. Plants should preserve their individual character in due subordination with the general arrangement, and not be jumbled up unmeaningly together to the ruin of all true effect. If, indeed, plants had less beauty than they actually possess, still it must wound the soul of the observer to witness the harshness and inconsequence with which they are often treated. Contrast, when rightly used, is, in truth, the source of developing great beauty; but if we neglect the comparison of our subject the results must prove unsatisfactory. In contemplating some scene of natural beauty with its refined foreground dying away into infinity, the soul is, as it were, filled up with and steeped in its harmony. No work in which the principles of harmony are violated can further the true interests of art, while those which instil a just feeling of union with the subject, must necessarily do good. It is easy to find examples. Scenery, indeed, must be true to Nature and effect, else the results cannot possibly prove satisfactory." Again, speaking of the lines of infinity and mass, whatever those may be supposed to mean, he says in his chapter on "General Observation for Beauty," "These lines should be used according to the natural formation of the ground to be beautified. No straining should be attempted to give more than is natural to the place, in just proportion of feelings, for there are plants of infinite characters which will beautify either small or large effects. Thus, the line curving concavely, in all its various forms, towards the individual, gives material to the mind; and the line curving convexly, or from, gives him occasion for thought. Thus the beauty of each character, in its development, gives either its material or thought to the mind." The latter part of this quotation might, we think, be more plainly and common-sensely defined, by saying, that the concave line and the objects of which it is composed, present to the eye the line of present enjoyment; the convex line, on the other hand, represents the line of prospective or future enjoyment. Again, speaking of the planting of shrubs with reference to outlines and masses, we quote the following: "Although these two effects of vegetation—outlines and masses—produce an impression, more or less, on every person, for you cannot pass a shrub or tree, even buried in thought, without receiving an invisible influence, communicated by their masses and outlines, yet the details must have one's particular attention before one can see them. But the subjects that surround you guide your path and meet every view of your eyes, shedding an influence over your life, such as every person is not aware of; therefore, the general outlines and massing of vegetation should be carefully adjusted, and, on these two features of character I will venture to give a few remarks." These are followed up by detailed mention of some shrubs, including Hollies, Yews, and Rhododendrons, with special reference to their outline and mass peculiarities; concluding with a list of miscellaneous evergreen and hardy shrubs, he finishes as follows. "Much of the art of arranging vegetation consists in placing the character of the plants planted into harmony suitable to the scene intended to beautify," which sentiment we hope our readers fully appreciate and understand, in which case we can only plead that they have the advantage of us. These quotations, will, we think, amply exemplify the style which the author has unfortunately adopted, and fully confirm the correctness of our opening remarks. Yet, though this style unmistakably pervades every page of the book, there are passages occurring here and there that indicate a poetic mind and one capable of appreciating Nature: in illustration of this, take the following as a sample:—"There are various natural scenes which show forth beauties from early spring till latest autumn without any assistance from art. Some old Hawthorn hedge, for example, will display a pleasant bordering of early Primroses and Violets, and, when May arrives wraps itself over with fair sweet flowers. Then the wild Rose peeps forth with her lovely delicate buds, and in autumn Rose and Thorn alike vie with each other in bright array of scarlet fruitage, a perfect delight to look at, yielding a regale for birds in requital of their songs. Yet many a scene would manifest results not less charming than these, would we only avail ourselves of Nature's guidance, but led astray by

* "Landscape Gardening for Perpetual Beauty." By J. F. Johnson, Curator of the Royal Botanic Gardens, Belfast. Belfast: C. Aitchison.

technical principles, we fail to understand and miss the pleasures which otherwise we might enjoy." Here we are at one with our author, especially in the latter part of the quotation, which appears to militate strangely with the general feeling as expressed in the work before us, consisting, as it does, almost entirely of an enunciation of those vague technical principles, which he himself thus condemns—less of them and more of Nature, and the power of appreciating Nature ought to constitute the stock in trade of a landscape gardener.

Turning to the chapter on "Town parks," we were much disappointed to find that little more than a single page is devoted to this subject. Surely the importance of additional park accommodation, and the equal importance of turning those that are in existence to the best account, might have formed subject matter for a lengthy dissertation—nay, more, we think, our author might have found therein illustrations accessible to all—of those grand principles which he wishes to impart to his readers, and thereby have verified the old saying, that "an ounce of practice is worth a pound of theory." In speaking of trees for town parks, he appears to ignore the Platanus, giving prominence to Robinias, Birches, and Maples, none of which are, for one moment, to be compared to the former as town decorative trees. The concluding chapter, devoted to "the Pinetum," consists of about three-quarters of a page; and out of the long array of Conifers—not all of which, we admit, are valuable, from a picturesque or economic point of view, but, nevertheless, many are—our author's brief summary under that heading consists only of *Pinus austriaca*, *Abies* (which, he does not say), *Cedrus Libani* and *Deodara*, *Pinus Sabiniana* and *excelsa*, *Taxus baccata fastigiata*, and *Picea nobilis*! Where are all the goodly array of *Araucarias* (not, we believe, once mentioned in the book), *Sequoias*, *Taxodiums*, *Junipers*, *Cupressus*, *Thuja*s, *Libocedrus*, *Retinosporas*, &c. Should this work of Mr. Johnson's reach a second edition, we would strongly suggest a limitation to broad and oft repeated platitudes, that refer, in the most indefinite manner, to everything in general and nothing in particular, and an extension of the subjects of these two chapters. Parks and town decoration are the order of the day, and most certainly belong to the proper sphere of landscape gardening, not architecture, to which fact Leicester Square, as modernised, bears ample testimony; and Pinetums are yet in course of formation, and have not become things of the past, as our author's cursory allusion to them would lead one to imagine.

The work is illustrated by eleven plates, or, more properly, diagrams. These, to some extent, help to explain the author's meaning, but they are far below the standard which the art of wood engraving has now acquired. We cannot leave this book without quoting a paragraph from the introductory chapters that we think, as proceeding from a young author, might well have been excised from the manuscript by the pen or scissors of "the learned friend" before alluded to. It is as follows:—"Much mischief, undoubtedly, is often unwittingly done by bookmakers who dish up other people's brains in such a fashion that, so far as horticulture is concerned, one might as well read a romance as peruse their writings. Disgusted with plagiarism, many give up reading on these subjects altogether, and thereby lose what might prove beneficial, along with what is otherwise. It is, however, very possible to re-discover a truth that was known before." Such a sweeping and ill-natured condemnation would have been much better omitted. No doubt Mr. Johnson himself has re-discovered truths that were known before—aye, and that were clothed in much more intelligible language than he has disguised them in, long before he was born. Considering the many curiously involved ungrammatical and hopelessly meaningless sentences in the book, we are surprised to learn, from the preface, that Mr. Thomas Moore, of the Chelsea Botanic Gardens, has looked over the proof sheets. Yet the book abounds with such sentences as the following: "*After that the spirit is placed in the material of beauty, observation may be made on parts of its diversification!*" (p. 31). "*In beauty, form and colour are one; its form giving you Nature's character for the present and future; while its colour tells you its permanent impression on its light pleasant thoughts*" (p. 109).

TOWN WINDOW GARDENING SOCIETIES.

In London, Hull, and elsewhere, societies have been formed to encourage window-gardening, and wherever the beneficial influence of such societies has been exerted they have done much good. Many a dingy home has been made all the brighter by the plants grown in them under the fostering influence and encouragement of such societies. Nor has it been essential to the happiness of the owners that a high standard of plant cultivation should have been set up. If only a plant will live, preserve its leaves green, and occasionally gladden its owner's eyes with a flower, then the causes for supreme satisfaction are quite ample. Now and again it is possible to meet with really well-grown plants in the homes of the very poor, and we well remember on one occasion to have seen in the window of a small house in one of our back streets nearly a dozen healthy vigorous plants which would not have been discreditable in any cottage window in the country. This by way of encouragement. There are many plants which will thrive excellently well even in the smoke of large towns, provided they receive a few extra attentions. For instance, the soil in which they are planted should be fresh and sweet, and should be renewed at least annually; the dust and dirt which will be certain to accumulate on the leaves day by day should be occasionally removed—the oftener the better—by sponging, or the rougher and readier method of sprinkling, or the more simple one of exposure to gentle rains when they fall. Then, again, plants should, on the one hand, never be over-watered, so as to convert the soil into mud; nor kept without water too long, so as to convert the soil into dust. With such means most of the more robust plants which commonly adorn cottage windows will grow and do well in those of towns. Evergreens of many varieties are well adapted for permanent occupancy of such positions; for, owing to the harder and oftentimes glossy surface of the leaves, they are hardier than most soft-wooded plants. The Cactus family, again, and many of the succulents, will for a long time bear up against rough usage and neglect, and the other adverse circumstances attendant upon town gardening; and their uncommon styles of growth, and flowers quaint and strange in appearance, invariably produce unflagging interest. Bulbs of many sorts, too, are particularly suitable to fill creditably a prominent place in a town window. We should like to know that window-gardening societies were established in all our populous towns. They would accomplish a really good work, and would encourage many who are now inert to become cultivators. The duties of the committees of management would not be arduous. They might well undertake the printing and distribution of such a code of instructions as would be readily understood by all who could read. They might purchase and distribute, at the lowest possible price, suitable plants, bulbs, &c., properly potted. They should arrange for the holding of two exhibitions every year—one early in spring, when bulbs should be shown; the other some time in the summer, for plants generally. They might also arrange for the occasional delivery of simple, but instructive addresses on plant life and plant growing in various parts of the town. They would also have to collect funds, in order to cover necessary expenses and provide prizes, which might be in money, plants, books, or useful domestic articles. To make the society as powerful as possible, it would, perhaps, be advisable to arrange for the organisation of two bodies—the one central, the other local. The local sub-committees should, perhaps, be as numerous as the ecclesiastical parishes or the municipal wards. They should be chosen by the residents in their respective districts. The central committee might consist of representative members of the local ones, one or two selected from each, with the addition of perhaps a few other persons chosen by these local representatives. The work of the central committee would be to raise the necessary funds, to settle the rules, to fix the exhibition days, and to award the prizes; while the local committees would have to work up their several districts, diffuse information respecting the objects of the society, put themselves in personal connection with the class in which the exhibitors would be found, and in other ways help on the work of the organisation. By such a dual arrangement an immense amount of work might be done, while no one person's share need be overwhelming. The connection between the localities each being represented in the central committee, would be mutually helpful, and, if well managed, the society would prove all powerful in carrying out its objects. Here, then, we venture to submit, is a plan capable of yielding admirable results, and which all classes of the community can assist either by subscription or personal work, or both. Cannot such an organisation be started (says the *Midland Counties Herald*) in Birmingham forthwith. No one need be frightened at the labours involved, or the amount of money to be raised. £100 per annum would do the work magnificently; half the amount might possibly be sufficient to start with, and to do it fairly well. The writer of this article was, not very long ago, instrumental in setting on foot in a large town in Lancashire, a small but successful society of this kind.

THE FLOWER GARDEN.

COW-PARSNIP-LEAVED MONTAGNÆA.

(M. HERACLEIFOLIA.)

THIS, one of the most stately of all half-hardy plants, has been rescued from obscurity to decorate our sub-tropical gardens. It is readily propagated by means of cuttings made of the root, inserted in pans of light sandy soil placed on a genial bottom heat. The plant itself grows rapidly if planted in a deep, rich, moist soil, in a sheltered situation, often attaining a height of from 10 to 12 feet in a single season. Its great cut leaves, which measure from 2 to 3 feet in length and about 2 feet in breadth, droop gracefully on all sides. It is useful as a conspicuous central object in a group of outdoor foliage plants, such as Yuccas, Solanums, Tobacco, Pampas Grass, Reeds, and Grasses, while it also makes a stately and noble object planted out in a cool conservatory along with other more tender foliage plants and Ferns. Our illustration is a representation of a well-developed specimen of this plant, which is well worth a place in all gardens, either massed along with other robust-habited plants, or planted singly in sheltered portions on the lawn or pleasure grounds. B.

NEW HARDY BEGONIAS.

I HAVE now in bloom three new seedling hybrid Begonias, raised by M. Lemoine, of Nancy, from whom I received the tubers in a dormant state in the month of April. They are named respectively Rubens, Velours, and Leviathan; the two former resemble *Intermedia* in habit, sending up a stem about a foot in height, and producing flowers in profusion from the axils of the leaves. The flowers are produced in bunches of three, composed invariably of a male in the centre, with a female on each side; the centre flower is much larger and finer than the side ones, but, unfortunately, usually drops off as soon as ever the female flowers are fertilised, thus seldom remaining on the plant more than a day after opening, though the female flowers remain in beauty for several days. The flowers of Rubens are of a fine carmine-blood colour, and the blooms of that variety are a size larger than those of Velours, which, however, is a shade deeper in colour than the former variety. Leviathan, much the strongest and most vigorous-growing of the three varieties, closely resembles Veitchii in its habit of growth, and produces its fine bright fiery orange blooms, on tall foot-stalks, well raised above the foliage. All these fine hybrids were raised by M. Lemoine by crossing B. Veitchii with Pearcei and cinnabarina. I also received from Nancy, at the same time, bulbs of three other varieties of Begonia, named, respectively, C. Glijm, Mastodonte, and Camoens, the first named failed to grow; the latter being small weak tubers have not yet bloomed, but the last-named will, I think, produce a

bloom or two before the end of the season. The rare and beautiful Begonia octopetala, from the Peruvian Andes, is now coming into bloom with me, planted out in the open garden in the same bed with the other varieties, and without any kind of protection whatever. Its leaf-growth is most healthy and vigorous, resembling small Rhubarb leaves, thus showing that this fine variety is quite hardy in this climate in summer, and in no wise requires the temperature of the hottest part of the stove, as stated in the account of the plant in the "Botanical Magazine," vol. 64, when the plant flowered in the Glasgow Botanical Gardens late in the autumn of 1836, the result of this over-kind treatment being the destruction of all the bulbs sent over from Peru, and the loss of the plant to European collections till re-introduced by Messrs. Frabel, of Geneva, in the spring of this year. W. E. G.

Montagnæa heracleifolia.

AUGUST FLOWERS IN HYDE PARK AND KENSINGTON GARDENS.

THE excessive care taken of some of the flowers planted on the bedding and ribbon-border system has been so judicious, and the watering so copious, that, in spite of the utter failure of the bedding system in most places, it has been comparatively successful this season in Hyde Park and Kensington Gardens. The small flower garden about the cottage in Kensington Gardens, which for many years has been so richly filled with masses of colour, is this season quite ablaze with brilliant hues. The devices are so good, and the plants composing them so closely grown and profusely flowered, that all London devotees of the bedding system should hasten to see them before the early autumnal frosts begin to nip their beauty. The mixed borders, along what is popularly known as the flower walk, have received nothing like so much care. The fact is, that most gardeners devote their chief attention to the close bedding system, which produces showy effects with little effort. This is a source of regret to those who prefer the natural to the artificial in garden effects, as it leaves the general public to imagine that a mixed border, as rich in masses of colour as a geometrically-arranged bed, is simply an impossibility. This is a great mistake, for picturesquely-irregular flower masses, either on open lawns or in front of shrubberies, might, with half the care and expense devoted to the geometric system, be made equally rich, and far more various in effect; for the bedding system, as at present practised, confines the gardener to a very small list of plants to select from, as, for instance, Pelargoniums, Verbenas, Calceolarias, Lobelias, and about half a

score of other things, which, on account of their compact growth, lend themselves to the system. A mixed border, or mixed lawn bed, on the other hand, is susceptible of an immense variety of treatment, by means of plants of countless kinds, and endless and striking deviation of form and colour. To effect this, however, with all the beauty of which the system is capable, necessitates much study, and that of a higher kind than is required to close-pack rich effects in geometrical devices. It also requires much more extensive knowledge of plants, and such pictorial taste as is required for painting a landscape on canvas. Painting natural landscapes in living flowers, in the highest style of

which the art is capable, requires, perhaps, even a wider range of artistic knowledge than that of the painter, though of a strictly special kind.

Leaving Kensington Gardens, and keeping the western bank of the Serpentine, the rock-work is reached; this feature of the park-gardening appears to be in a somewhat neglected state. The rock masonry itself is improved, by being much more completely clothed than it has been with trailing plants, such as Ivy, Periwinkle, St. John's Wort, Saxifrages, and other more or less suitable plants; but dead bushes require clearing away, and other rock-growing shrubs planting to fill gaps. Along the front there are many small compartments which are needlessly empty; but advantage should be taken of that circumstance to prepare for the sort of spring display for which such spaces are calculated. Cyclamens, the hardy kinds, might, with proper care, be made to do well. Squills of various kinds, and common Blue Bells, both blue, white, and lilac, would tend to make this rock-work very gay in early spring; to say nothing of Hepaticas, blue, white, and pink. It does not seem, too, that either Wallflower or Antirrhinum seed has been scattered in places decidedly favourable to their growth. Young Wallflowers should be now strong seedling plants *in situ*, which in due time would make a splendid show of colour, and fill the air with delicious perfume. There are, also, several kinds of Lilies which delight in establishing themselves permanently among the interstices of rock-work. About the narrow wending water the ground is kept in excellent order; and its slopes and well-grown trees, of various kinds, render it very attractive. There are, also, some beds of flowers on the bedding system, which, from being partially shaded, and near the water, have defied the drought, and are in very luxuriant bloom; their excessive formality, however, produces anything but a natural contrast with the irregular character of the ground and foliage among which they have been placed. In this spot, without interfering with the plans adopted in other parts of the park, experiments of a natural kind of bedding out might be tried, distinct from the ordinary geometric system. For instance, let the beds be of excessively irregular and natural form; let them, in some cases, run down to the very water's edge; in other cases let them lose themselves among the trees. In filling them with the usual bedding plants, let these be placed in irregular masses, in which they might be supposed to have sprung up from seed. Let a couple of well contrasted colours predominate—massive irregularity—not indiscriminately mixed, but each having one or two stragglers, but not more, of the other kind, capriciously breaking a too monotone character; then let the other spaces, all irregular, be filled with smaller masses of striking colour, broken in one or two places, but not more, with solitary touches of the predominating colour. Here is a suggestion for a new kind of bedding, which would blend harmoniously with the slopes of irregular ground, or an irregular distribution of trees and shrubs. The lawns and flower-beds, which form such a vast improvement in that part of the park which lies between the southern, or rather south-eastern end of the Serpentine and Apsley House, are in very fair order; but their extent has prevented that copious supply of water, which, alone, could have preserved them quite intact from the effects of the excessive heat and drought of the season. There are good effects produced among these large lawn beds by the use of tall-growing semi-tropical plants, distributed sparsely among the masses of Cannas and other plants which are grown more for their luxuriant foliage than for their flowers. One expanse of the kind, varied by tall sprays of *Ficus elastica*, has a very pleasing effect; and there are many other combinations, produced by means of less known plants, which are equally successful.

The series of geometrical masses of flower-colour which stud the whole line facing Park Lane with expanses of crimson, purple, scarlet, pink, yellow, blue, and many intermediate hues, are, on the whole, successfully managed this season. Profuse watering has preserved them from the effects of drought, and the plants, with the exception of the *Calceolarias* and *Verbenas* (which are this season comparative failures everywhere), appear just now in robust health and extremely profuse bloom. The walk between these masses of flowers is evidently a favourite resort, and its present high state of keeping is certainly a boon to the population of London. Two or three advantageous innovations upon the extreme regularity of the system may be noted. The dazzling scarlet of some of the *Pelargoniums* with variegated foliage, is both heightened and varied in a neat and pleasing manner by the introduction of a few detached specks, as it were, of *Viola cornuta*, the pale but bright purple blooms of which, sparkling here and there, have a most pleasing effect. Another good effect of an analogous, but more striking kind, is where a bright green-foliaged plant, mottled with yellow, is dotted sparingly among the velvety crimson masses of the gorgeous *Coleus Verschaffeltii*.

AN AMATEUR.

Herbaceous v. Bedding Plants in 1874.—Many will be astonished at the statement (p. 118) that Mr. Pearson, of Chilwell, considers that the present season has shown the superiority of the bedding system over the mixed border. Here, at least, it is exactly the contrary. All things planted out since the 1st of May have had a hard struggle for bare existence, except in cases where there was a ready access to a plentiful supply of water. Well-established perennial plants have alone succeeded. Some of these have done very well, and most have done fairly, except *Phloxes* (a very thirsty family) and *Lilies*. The latter have been stunted in their growth, except the old *L. tigrinum*, which I never saw better. There is one class of plants which is too much neglected (and which ought to form a portion of every mixed border), which deserve especial notice this year; I allude to flowering shrubs, which have, in almost every instance, flourished well; *Yuccas*, too, have been in great beauty.—HENRY H. ELLACOMBE, *Bilton Vicarage*.

Spiræas for Forcing.—*S. japonica* is decidedly the best of all the *Spiræas* for forcing, and it is also one of the most beautiful of pot plants. This is the opinion of Mr. Herbst, of Richmond, who supplies Covent Garden with the earliest plants of it. *Spiræa filipendula* has been tried, but although it produces pretty white flowers, they are useless when cut, as they do not last any time. *S. palmata*, he says, has the same fault, and, moreover, does not force well; and he also dislikes *S. ciliata*, the flowers of which, although very pretty when seen from a distance, have, when closely examined, a coarseness about them that detracts from their value; besides, the blooms on the lower portion of the branchlets of the spikes begin to fade before those at the end have expanded.—W.

How Moss Roses are grown for Market.—Moss Roses are largely grown for the London markets; they thrive pretty well under trees, and are very hardy and floriferous. Light, rich, and deep ground suits them best. Two rows of these Roses are generally planted between Currant and Gooseberry bushes, about 2 feet apart, but as suckers speedily make their appearance, all traces of rows become lost, and the result is a broad band of Roses, some 2½ or 3 feet wide, occupying the central space between the bush fruit. Under fruit trees where no fruit bushes exist, they are grown in lines 2½ or 3 feet apart, and interspersed with sprouting Broccoli, Brussels Sprouts, Potatoes, or Shallots, and they are also grown in the open ground, about the same distance apart. After they have done blooming, and have made good wood, they are layered on both sides of the rows, and in October, or any time between that and the following March, the layers are lifted, and after their roots have been dressed, and their tops shortened a little, they are planted out in permanent rows from 2 to 3 feet apart, or if space is scarce at the time, thickly in rows a foot or eighteen inches apart, where they remain for twelve months before being finally planted out. They are pruned very closely in winter, and in spring they begin to form flower buds, almost as soon as the leaves make their appearance. It is the buds that are gathered for market, the blooms never being permitted to expand. In hot summers, and indeed, whenever convenient permits, the space over their roots, 2 or 3 feet in width, is mulched with litter, which saves them from drought, and also acts as a stimulant.—F.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Lilium auratum.—One of our customers, writing on the 4th inst., says, "My plants of *Lilium auratum* have been very fine this year, having produced stems from 6 to 10 feet high and blooms varying from twenty up to nearly a hundred on a root; some blooms measuring nearly a yard in circumference."—A. W.

Yuccas.—These have been particularly fine this year. *A. Y. recurva* in my garden has been looking perfectly beautiful, its panicles of creamy-white blossoms being unusually showy; and I am sure that all passengers who have stopped at Liss station must have noticed some remarkable *Yucca* bloom in a small border adjoining the platform; but, as you justly observe, *Yuccas* should be grouped to obtain the best effects which they are capable of producing.—H. G. WATNEY.

Bravoa geminiflora.—You state (p. 92) that this plant succeeds well treated as a half-hardy pot plant. Some of your readers, however, may have found, like myself, that success in making it flourish is far from easy. I would advise them to try it as a hardy plant. I have had it for some years, and never could do anything with it in the greenhouse; but last autumn I planted it in the open ground, and this year it has come up very strong and healthy, and flowered well.—H. N. ELLACOMBE, *Bilton Vicarage*.

Lasting Sweet Peas.—If properly grown, Sweet Peas will bloom for months; failure arises from poor soil, sowing too thickly, and not allowing a well-developed growth. To keep up the bloom, the seed pods must be promptly removed, as the growth and ripening of seeds would exhaust the strength of the plant. By this process they will bloom all summer and until frost. The soil should be rich, deep, and moist.—Q.

Great White Thrift (*Armeria cephalotes alba*).—This is now blooming beautifully in the Wellington Road Nurseries. It is a handsome robust-growing perennial, which, when in flower, is very effective. The blossoms are pure white, and are borne in large roundish heads on erect stalks. It is a plant which will, doubtless, succeed well in warm positions on rock-work and in well-drained mixed borders in deep sandy loam.—M.

THE FRUIT GARDEN.

BUSH FRUITS IN MARKET GARDENS.

IN market gardens as in nurseries, bush fruits are propagated by means of the finest of the prunings of the young wood saved at pruning time for that purpose. They are collected, tied into bundles, or laid in by the heels loosely in bundles until the whole of the pruning has been finished. They are then lifted and made into cuttings about 10 inches or a foot in length. All buds on the lowermost half, or as far as they are intended to be inserted in the ground, are removed; for if left untouched, they would produce suckers that would ultimately prove troublesome. The ground for their reception being trenched and manured, they are inserted firmly in lines about a foot apart, and 2 or 3 inches asunder in the rows. Sometimes the cuttings are put in as the ground is being trenched. The first spring Lettuces are generally grown amongst them. In some instances, too, the cuttings are inserted in a line along the base of a wall, having an eastern or northern aspect, and about a foot from it. Both Gooseberry and Currant bushes are also increased by means of layers. In March, whole rows of bushes are layered, somewhat young and supple branches being selected for that purpose: their points are cut off, and the branches are kept in the ground by means of wooden pegs, slightly covering the portion layered with soil. When they begin to grow, shoots push from every joint, and no sooner have these young shoots attained a length of 6 inches or thereabouts than they receive another good earthing up, which is done by loosening the soil in the alleys, one man making it quite fine with a spade and throwing it into the centres of the bushes and over the layered shoots, whilst another spreads it regularly with the hand, so as to cover the base of the shoots to the depth of a few inches. In this condition they are allowed to remain throughout the summer, receiving no further attention beyond that of keeping them free from weeds. In October, or any time between that and the succeeding March, the layers are lifted, cut up into pieces, leaving two or three shoots on each, and transplanted in nursery lines, in which they are allowed to remain for another year. They are then lifted and transplanted to their permanent quarters, and all surplus stock is sold. Market gardeners generally grow their fruit bushes under trees where they are liable to many disasters, such as becoming overrun with Lichens, broken, or choked, on account of too much shade; and the reason why plants having two or three branches springing directly from the root are best, is, that if they happen to lose a limb, still one or two sound ones remain; while, had there been only one main stem, all would have been lost, and a fresh plant would have been necessary.

F.

THE WILD PLUMS OF TEXAS.

ON reading Mr. Thompson's interesting letter (see p. 110) describing the wild Plums of the Kansas plains, I was reminded of the wild Plums of the Texas prairies, which, during a residence of ten years in that state, I had frequent opportunities of observing. As in Kansas, so in Texas, the favourite habitat of the wild Plums is at the head waters of the rivers; but I found them only in the most fertile soils, never in the sandy regions. I am of opinion that the Texan and Kansan Plums are of the same species, as I traced them through the Indian territory, close to the border of Kansas; but I do not think, as Mr. Thompson would appear to indicate, that the dwarf and tall are the same, and that the difference of habit is attributable only to difference in fertility of the soil in which the plants happened to be growing. I found the dense thickets of the dwarf or bush Plum (Hog Plum the Texans call it) invariably in the richest soil, and in moist localities of the open prairie, whilst the tree Plum, attaining a height often of 20 feet, as invariably locates itself in the midst of a grove of other trees, affecting rather the outskirts than the interior of such grove, and of which, by its white blossoms in spring, and its brilliantly-coloured fruit in summer, it forms the chief adornment. But the fruit of the Texan Plum, whether tree or bush, is far below the Plum of Kansas, as described by Mr. Thompson, in the important qualities of size and flavour. The fruit of the bush or Hog Plum resembles a May Duke Cherry in size, colour, and form, but in flavour it is not very much better than our common Bullace. The fruit of the tree or grove Plum has great beauty of exterior, glowing in all the brightest hues of scarlet, orange, and yellow; but in size it is

not bigger than a good Gooseberry, and although not unpleasant to the taste, and largely used by the settlers in making preserves, has far too much acidity to bear comparison for a moment with cultivated English varieties. Assuming the dwarf species to be a bush, and to remain so under any circumstances of probable culture, there remains only the melioration and enlargement of its fruit by that process of careful selection so well understood by the painstaking pomologist, to make out of this now insignificant Plum, in a few years, a valuable contribution to our fruit gardens and orchard houses.

The Torbay Nursery, Torquay.

J. H. MORGAN.

FORCING STRAWBERRIES.

THE potting of Strawberry plants, and the size of the pots in which they are put, are important matters as regards forcing, and are, in fact, next to the securing of early runners, the points upon which success hinges. It should be known that the thorough maturation of the plants is essential to success. The runners should be potted in time to fill the pots with roots before the end of September. No plant can be depended upon to produce fruit that is not in this condition, for while they have room to grow they will not ripen their buds perfectly. I like to see the roots almost bursting the pots, and just in that matted condition that you might turn the plants out of the pots and pitch them about like a ball without breaking them. Different varieties, of course, require different sized pots; but on no account should 6 in. be exceeded, and 5 in. will be found a proper size for general purposes. Six-inch pots should be used only for the strongest growing kinds, and for these only when they are potted early in the season—say between the middle and the end of July. The longer potting is delayed the smaller the pots should be. It must be remembered that a plant potted at the beginning of August has little more than six weeks to complete its growth and cram the pot with roots. I never reckon on any real growth after the middle of September. Chilly nights then begin to check their progress, and the leaves get less and less in size till growth ceases. The beginning of August sees all our plants into their fruiting pots from the Strawberry bed, for I always layer the plants in ridges of soil from which they are transferred to the fruiting pots at once. For Black Prince $4\frac{1}{2}$ in. and 5 in. pots are used, 5 in. pots for Prince of Wales and Haricart de Thury, and others. Strawberries should always be potted as firmly as can be done with the fingers and thumbs. About $\frac{1}{2}$ in. should be left for watering, and when newly potted they should be set closely together, to shade one another's roots until they are established and grown a bit, when they may have more room. I find a goodish sprinkling of Standen's manure (which is a kind of concentrated bone-dust) mixed with the soil, to be an excellent and immediate stimulant. Some of the best forcing Strawberries are so subject to mildew when forced, that many dare not grow them for forcing at all. Among these, Black Prince, acknowledged by all to be one of the earliest, most prolific, and easiest to force, is about the worst. I have so often heard of its being given up for that reason, that a word of advice at this season, when pot plants are being prepared, may be acceptable. I have forced Black Prince now for ten years, and during that time, owing to the simple precautions I always take, mildew has never given me the least trouble, I should be loth, indeed to give up this variety, for as a forcer it is a regular "fill basket;" never a single plant missing to fruit abundantly; and, though it is reckoned a small sort, the berries with me always run from about 1 inch to $1\frac{1}{2}$ inches in diameter from plants in 5-inch pots, and carrying each on an average from six to ten fruit. It is known that sulphur will arrest the mildew, but in consequence of its being applied at the wrong time, or too often, it adheres in a hardened condition to the berries, and the cure is about as bad as the disease. Now, it is rarely the plague appears on the plants to a serious extent before the berries are set; but it never fails to come then, and its presence may be detected at once by the white powdery-looking patches upon the leaves, and on the foot-stalks of the berries. This is the time to attack it, or at least to apply the sulphur, whether it is visible or not. If it is applied sooner it begins to lose effect when the berries are about half ripe, and, as the sulphur cannot then be applied, it will ruin them. The first-set berries are of course always the largest and best, and as soon as six or ten are set on each plant, and just set, then apply the sulphur. I am, of course, presuming that the earliest set plants are gathered together on one shelf, or at one part of the house. There is no way of applying sulphur so effectively as by means of the syringe, but it should first be disintegrated by mixing it in skim milk. About one pound will do a great number of plants, and it will require about one pint of milk to that quantity. Stir it well in the milk till it is thoroughly broken up, and then pour it into the water with which the Strawberries are to be syringed, and keep stirring

the water while syringing to prevent the sulphur settling to the bottom. Thoroughly deluge the plants right and left, till the sulphur can be observed on every part of them in minute particles. Smearing must be avoided, but there is no danger of this if the sulphur has been well disintegrated in the milk before using. No further application will be required after this, and the berries will swell off clean and beautiful without a speck of sulphur being visible upon them. I seldom syringe the plants after sulphuring, as it would wash the sulphur off. If the plants are well watered at their roots, and the house damped on bright afternoons, syringing will not be necessary. J. S. W.

THE GARDEN IN THE HOUSE.

DINNER-TABLE DECORATION.

Arches.

THERE is no prettier way of decorating a dinner-table, if oval or circular, than ornamenting it with a handsome arch, which is, moreover, by no means difficult to arrange effectively. It should, however, be remembered that, as a rule, no well done or elegant floral arrangement can be put together without a little trouble. The size of the arch itself must, as a matter of course, be proportionate to the size of the table on which it is to be placed; and, the size having been determined, next comes the material of which the arch is to consist. This should be strong wire, stiff enough to keep its form without bending, and each end should be inserted in a piece of iron or lead in the form of a large flat weight, which forms the stand. These supports should each be placed in a circular zinc pan, and packed in with damp silver-sand to keep them firm. Means are thus provided for having a group of flowers at the base of each end of the arch, which, together with the zinc pans, should be painted green. The shade of green selected should be as near as possible that of the Ferns usually arranged round the edge. The next thing to be considered are the creepers with which the wire arch is to be covered. Of this class of plants there is such a variety (some hardy, others tender) that it would be impossible for me to enumerate all that are suitable for the purpose. I always use two plants of the Creeping Fern (*Lygodium scandens*) for arches. Each plant is turned out of the pot in which it is growing, the soil is shaken from the roots, and it is replanted in the zinc pans of sand. This is a better plan than cutting off the fronds and inserting them in the sand, as, not being cut, they remain fresh for a much longer period than otherwise they would do. Through the *Lygodium* sprays of *Lapageria rosea*, or its white flowered variety, may be twined with good effect. On the centre of the table, under the arch, a pot plant is often placed, but I like best to see a small stand of flowers in that position; it must, however, be small, or it will detract from the effect of the arch. For this purpose, a small-sized flat tazza, with a trumpet rising out of the centre is best. Were I about to arrange a table in this style, say in the month of June, I should select the following flowers:—Round the edge of the tazza I should arrange, lightly, fronds of *Pteris serrulata*, in the tazza itself some blooms, say two Pink Cactuses, the same number of Water Lilies, a few sprays of Pink and White *Rhodanthe*, and four fronds of Maiden-hair Fern. Down the trumpet I should twine a spray of *Lygodium scandens*, and in the trumpet itself I would put a plume of wild Grasses, *Rhodanthe*, and a few fronds of Maiden-hair. The arch I should cover, as I said before, with plants of *Lygodium scandens*, and in the pans, I should arrange some of the flowers just named, with the addition of a few half-open Rose buds, blue Forget-me-nots, or any other suitable flowers which may be at hand. Round the centre vase might be placed a few specimen glasses, each containing a Rose, bloom of *Eucharis amazonica*, &c., each backed by a Fern frond. In some cases a plant is set under the arch, let through the centre of the table, and at the ends of the arch growing plants are often placed in the pans, instead of cut blooms. Those who do not have glass houses in which to grow *Lygodium scandens* or other creepers of that kind, might use in their places young shoots of Ivy, Japan Honey-suckle, or a spray of Passion-flower, and fill the pans or trays with whatever garden flowers are obtainable. It is useless for A to say to B, you should use so-and-so, and place this next to that, as perhaps B may not possess half of the plants

named by A. What, therefore, I wish to describe is how this style of management would look best, should the flowers recommended be at command.

Decoration Without Stands.

This also deserves attention, as one gets tired of getting up the same stands day after day, and unless one has a very long purse, indeed, vases cannot be constantly dressed afresh with flowers; I have therefore, had to manufacture (if I may so term it) stands of my own, the foundation of which is often a common soup plate, which if properly managed makes a charming stand. If I have friends at dinner, I use three plates; if for every day use only one. Let us first take three plates, which being obtained, the next important matter is to procure three nice plants to stand in them. That for the centre should be much taller than the others, say a nice Palm, the others being *Adiantum emeatum*, one of which should be set at each end, an arrangement about as good as any that could be made. Having placed the pots in the plates, they should be packed in with damp silver-sand in the form of a mound, so as to hide the pot; the surface of the sand should then be covered with fresh wood Moss, or better still, if you have it, growing *Selaginella denticulata*. This done, the next thing is the arranging of the flowers, which I have done myself as follows; but it must be remembered that it was for a dinner by daylight, as many of the shades, if subjected to artificial light, would have lost their beauty. The pot plant which formed the centre piece, was a well grown *Cocos Weddelliana*. Round the edge of the plate I had a wreath or fringe made of the fronds of *Pteris serrulata*, interspersed with a few leaves of *Cissus discolor*. Round the base of the plant were then arranged *Gloire de Dijon* Roses, *Christine Pelargoniums*, Pink *Rhodanthe*, some sprays of *Iresine*, and a few fronds of Maiden-hair Fern. The two end plants consisted of *Adiantum emeatum*, and round their base I had some more blooms of *Gloire de Dijon* Roses; in place of the *Pelargoniums*, I had sprays of *Bougainvillea*, and I substituted some young brown shoots of *Roses* for the *Iresine*, finishing off round the edges with fronds of *Pteris tremula*. With reference to the single stand, it was dressed in March and was very effective by gas-light, to which, of course, at that season it was subjected. The pot plant which I employed on that occasion was *Pteris tremula*, and round its base I had white *Primulas*, scarlet *Geraniums*, and *Begonias*, *Snowdrops*, and Maiden-hair Fern, while round the edge were different varieties of Fern fronds. Sometimes the centre piece is a March stand, which, some think, looks better than the three alike; at all events it forms a change, and where this arrangement is adopted a quantity of wild Grasses and Horse-tails may be used in the centre piece, as well as in the end stands, with good effect. Nothing, indeed, tends to give such a light appearance to an arrangement of this kind, as plenty of wild Grasses intermixed with the flowers employed. In the end stands, Lily blooms take the places of the growing plants, and if the soil be kept damp, they will retain their freshness for a long period. *Lilium lancifolium*, both white and crimson-spotted varieties, are well suited for this purpose, the white more especially, a colour which does not interfere with any other with which it may be brought in contact; I have also seen *Lilium auratum* used for this purpose; but, though good, so far as form is concerned, its perfume is much too powerful, and many blooms of it in a room are undesirable. As a rule, all very fragrant flowers should either be avoided, or, at least, be used in small quantities.

A. HASSARD.

***Rochea falcata*.**—This old and well-known succulent is now flowering freely in conservatories and window gardens. It has glaucous fleshy leaves, and great dense heads of bright scarlet flowers, which contrast well with the bright green foliage of Ferns and other foliage plants of that kind with which it may be associated. The plant is readily propagated by inserting fully-developed leaves in cutting pans filled with light soil and surfaced with sand. These root and form little plants in a few weeks, and may then be potted off singly and grown on near the light. As a window plant, it has few equals when in flower, and it is always interesting as an indoor decorative plant. The secret in its culture is getting it to bloom in a dwarf state, and this is done by fully exposing the young plants in a sunny window or on a shelf in the greenhouse near the light.—B.

THE INDOOR GARDEN.

THE LEMON-SCENTED GARDENIA.

(G. CITRIODORA.)

THIS, perhaps the most free flowering species of the useful genus to which it belongs, deserves to be generally cultivated where choice cut flowers are in demand. It grows well in an ordinary stove, where its bushy habit, glossy green leaves, and dense clusters of flowers render it conspicuous, even among the most select of stove plants. Like all its congeners, it is readily propagated by means of cuttings inserted in a genial bottom heat, and young plants, if liberally treated, seldom fail to flower the first year. A rich peaty soil suits it admirably, and during the growing season it requires copious supplies of moisture both at the roots and in the atmosphere. Apart from its attraction as a decorative stove or warm greenhouse plant, its flowers are extremely useful for bouquets, and especially for button-holes, as they can easily be mounted on thin wires, either singly or in clusters. Like other Gardenias, this species is very liable to be infested with insects, which must be carefully looked after. Its pearly sweet-scented flowers, which are produced in winter, form a good substitute for Orange blossom, and on that account alone it deserves more attention than it at present receives. It is a native of Southern Africa.

B.

CHOICE CONSERVATORY CLIMBERS.

THE interiors of our stoves, greenhouses, and conservatories are necessarily of such a cramped and artificial character, of a style so much at variance with everything we are apt to associate with the highest type of vegetable beauty, that it becomes very desirable to drape them with vegetation, and to beautify them as much as possible without injury to the contents of the house, by placing the best climbers on such pillars, supports, or positions in the house as may be most suitable to them. Nothing can tend more to the embellishment of the indoor department than the introduction of a good selection of well-grown climbers, kept clean, and in graceful training. Some climbing plants, like the *Lapageria*, are so well known and appreciated as scarcely to require mention. My object is to add the names of a few subjects of first-rate merit not so generally cultivated. This remark, perhaps, hardly applies to *Plumbago capensis*, which is grown in nearly every garden. But how? In many old stoves it may be seen treated as a pot plant, with very trifling success, compared with what may be attained by planting it out in the conservatory. It is unquestionably the finest autumnal plant we have for a pillar in a conservatory or any large cool house, and the masses of lovely light blue it produces when in that position are

unequaled. With this *Plumbago* against a tall pillar there can be no mistake. The large class of gardeners who have to specially provide for an autumnal effect would do well to plant it, and, after taking it up the tallest pillars, to train it along the roof in wreath-fashion, if possible. In addition to the highest beauty and abundance of prolonged bloom, it has the great merit of being a clean plant, not a nuisance to keep clear of green-fly, like the *Mandevilla*, or of scale and mealy bug, like some of the *Tacsonias* and others. The treatment, too, is quite simple; cut in close in winter, and allow it to take its own way in the growing season, and thus will be secured a mass of pleasant green through the summer, and in autumn every shoot will bend down with its lovely crest of blue. It may be planted anywhere in the floor of a conservatory, or in a bed of any kind, and

should be cut in with a free hand in winter. *Cantua dependens* is magnificent when planted against the back wall of a conservatory, or in any suitable position in the conservatory, and allowed to make a free full growth there. It has a fine effect trained up a pillar. It should be planted in a good free loam, but it is not particular as to soil. In South Devon it flowers splendidly on the open walls. From the great fragrance and value in winter of the flowers of *Jasminum grandiflorum*—the Catalonian Jasmine—this plant is well worth planting out in an intermediate house or warm greenhouse, there to afford a profusion of its flowers—of so much importance for bouquet-making or indoor decoration, or, in fact, for any of the purposes of the decorating horticulturist. *Rhynchospermum jasmynoides*, so often shown well in pots, is a fine thing to plant out in the warm greenhouse or intermediate house. It should have a nice position near the glass, and requires very little more care as to choice of position and attention, than *Cobaea scandens* or *Passiflora cærulea*, with which some embellish their conservatories. One can fancy nothing more beautiful than wreaths of this *Rhynchospermum* in a rather low position near the glass towards the front of a house, of a temperature suited to its wants. It is a sweet and beautiful thing grown in any way. Wherever there are conservatory walls or large wall-spaces in conservatories, a place should be found for the *Datura*

Flowering Branch (reduced) of Lemon-scented Gardenia, and Bloom (natural size).

or *Brugmansia suaveolens*, a noble plant when planted in such a position, and whose large white pendent flowers, popularly called Angels' Trumpets, would diffuse their sweetness through the house, even though it were as large as the conservatory at Chatsworth. A fine flower like this, which open and breathes fragrance when animated Nature is drowsy or asleep, is certain to command admiration.—*Florist*.

Nertera depressa.—It is stated (see p. 123) that this beautiful little plant is seldom to be found in nurseries. I therefore think it right to mention that I have recently seen in the Lawson Nurseries, Edinburgh, upwards of 1,000 nice plants of it, many of them—from the smallest in thumb-pots to those growing in pans—exhibiting their tiny coral berries through a carpet of green foliage. This plant is mentioned by Lindley as the most southern species of the extensive family of which it is a member.—*EDINA*.

THE KITCHEN GARDEN.

HOW FRENCH BEANS ARE GROWN FOR MARKET.

Of all market garden summer crops this is the chief; for, when French Beans appear in the market, the demand for Cabbages, Cauliflowers, and Peas begins to decline, Vegetable Marrows being their greatest rivals. With the latter, however, it is possible to overstock the market, especially if they come in large quantities at the beginning of the season; but French Beans always command a sale, provided they are good and fresh, and overstocking the market with them is almost a thing unknown; but, when large quantities of them are introduced, prices are materially affected. The Valley of the Thames is, perhaps, unequalled as regards the growth of this crop, which does best in a deep soil not liable to excessive drought, and that is made light and rich by much working and heavy manurings. As French Beans are short-livers and gross feeders, they require manurial substances of such a character as can be speedily turned to account: therefore, land that was richly manured for the previous crop—such as for Celery—and that has also been liberally dressed with short manure, such as that from Mushroom beds or old Cucumber pits for this year's crop suits them best. Newington Wonder and Negro are the principal sorts grown in the London market gardens, and, although old varieties are reckoned to be the two best. Their productive qualities are great; for, when well attended to as regards timely picking of the pods, they continue fresh, vigorous, and fruitful for a long time, and their pods, as a rule, are less apt to turn tough and unusable with age than is generally the case with other varieties. The Black Belgian has also found its way into the market gardens; it is a good dwarf early sort, much like the Negro, of which it is considered to be a variety. It is very useful for late sowings, and for early framework. Mr. Myatt, of Deptford, prefers the Newington Wonder to all other sorts, and he has a dwarf prolific sort, with the name of which he is unacquainted, that is used for the earliest crop. The Fulham growers, on the other hand, prefer the Negro, which they grow in frames, as their earliest, main, and latest crops; but most of them now also grow a quarter of the Newington Wonder.

In Frames and Hand-lights.

The first crop of French Beans is generally grown in frames, and those just cleared of Cauliflower and Lettuce plants are the ones used for this purpose. The frames being already sufficiently filled with mould, it is pointed over with a spade, and the seeds sown, provided the soil is not cold and wet—which might easily be avoided by keeping on the sashes after removing the late occupants—in four rows under each light, and about 3 or 4 inches from seed to seed in the row. The middle of March is the common time for sowing in frames, and then the sashes may be kept close till the seeds germinate, when they should be tilted up a little at the back in favourable weather; but care is always taken to keep the sashes close in the case of cold winds, and to cover them over with mats or litter in the event of frost. As they advance they may certainly be treated more hardily, but judiciously, judging according to the weather. After the middle of May, when all fear of frost has passed, the sashes are entirely drawn off these frames throughout the day, if fine, and, as a rule, replaced at night. Beans are commonly picked from frames about the second or third week in June, or about three weeks sooner than the earliest border ones come into use. A few frames, too, are also frequently occupied by French Beans sown thickly, for the purpose of transplanting the Beans from thence to the open ground, and to fill any blanks that may exist in the frames in which the sowings for fruiting therein have been made. For the first out-door planting the warmest piece of ground or border that can be spared is devoted, and the Beans are planted therein in little patches under hand-lights. The usual way is, about the first week in April, to draw lines 3 feet apart across the border, and others 2½ feet asunder lengthways, and upon the middle of every little square thus marked place an ordinary hand-light, under which plant eight French Beans; but they must have been pretty well hardened off previously. If there are not sufficient hand-lights for the whole space to be planted, use half-bushel vegetable-baskets, which invert over the plants;

and, as they are so open to the wind, they should be covered for a time with mats. The hand-lights and baskets, being just removed from performing the same end for the Cauliflowers, are now available for the French Beans; from which, as soon as they have got a good hold of the soil and begun to grow, their protectors may be removed to fill a like office in the case of Vegetable Marrows. Great care must be exercised with hand-light Beans, otherwise they are a deceptive crop, and sometimes die off altogether, especially when nursed too tenderly and changed too suddenly, if the ground be cold and wet, and their top covering insufficient and permeable to frosty winds.

Outdoor Crops.

The first outdoor crop is usually transplanted thence from the frames, and the warmest possible position is selected for this purpose; the real time for so doing entirely depends on the state of the weather and nature of the ground. If the weather be fine, the soil moderately dry and light, and the position warm and sheltered, the plants are commonly transplanted sometimes during the first fortnight of April; but, if otherwise, they are delayed a little later. Last year Mr. George Steel had a fine plantation of early French Beans, treated as follows:—He had a long south border in front of a thick hedge, just cleared of Radishes, and this he got dug over, and lined off in cross rows at 18 inches apart, drawing the lines in the form of seed furrows with a hoe. Herein he planted, 5 inches asunder in the row, near the middle of April, Negro Beans raised in frames. They grew and promised well, until the hard mid-May frost that followed damaged them considerably; but they nevertheless recruited themselves, were earthed up in due time, and came into good bearing condition a fortnight after those Mr. Steel had growing in frames. Mr. Wm. Bagley and others erect barricades of mats in an upright position to stakes driven into the earth, and placed to the windward side of the borders; and they also surround frames containing them, but not covered with sashes, with the same protection to ward off cold and frosty winds, that are always detrimental to this crop. Sowing begins out of doors some time during the first fortnight of April, just as the state of the weather and soil permits, and the warmest available position, such as in front of a wall or hedge, is selected for the purpose. If the ground is free from all other crops at the time of sowing, there is more need for a sheltered place than if it were cropped. In sowing, the lines are drawn at 2 feet, 2½ feet, and sometimes at 3 feet apart, and the seeds planted about 4 or 5 inches asunder. The earliest crop, as a rule, is sown on empty ground, and that just cleared of Radishes, Spinach, young Onions, Broccoli, or Coleworts is what is generally used; or a piece of ground may be kept uncropped from the winter purposes for the Beans. The drills for the seeds are generally drawn with hoes in the forenoon of a fine day, and left open till the afternoon, when the seeds are sown, and some earth is drawn over them with the feet. When empty ground is not used for them, they are sown in drills drawn between lines of Cauliflowers, Cabbages, or Lettuces. These crops, instead of being injurious to the French Beans when they appear above ground, are simply beneficial to them, inasmuch as they protect the tender Beans from cold winds, and act like foster parents to them until the Beans have gained some strength and the weather becomes mild and warm, by which time the bulk of the Cauliflowers will have been removed for market. Even then, however, the French Beans do not get all the space to themselves, for no sooner is the earth cleared of the other crop than it is loosened a little between every alternate line, and those spaces replanted with Lettuces or Brussels Sprouts. Thus one space contains another catch crop while the other is empty; and, by means of having this empty space to walk in, the gatherers can pick two lines of Beans, one on either side of the empty alley, and, never disturb the other crops in the alternate alleys. Should the French Beans have come up well, and be nearly ready for picking before the first occupants of the soil are entirely removed, the alleys are not cropped again until the Beans become exhausted, when the ground is entirely cleared, and cropped with Celery, Radishes, Turnips, Onions, transplanted Leeks, Spinach, or Coleworts. The first main sowing is made on the open field about the end of the second or third

week in April, under the same circumstances as that already mentioned, or the field may have been previously planted out with Cos Lettuces in lines 1 foot, 15 inches, or 18 inches apart; between every two lines of these would be sown one of Beans, for which the rows are not drawn to a line, but merely done so by guesswork.

First Crop Failures.

Many failures of the first crop take place if sown too early, especially in the case of cold and wet soils. Indeed, in a market garden at Hammersmith about an acre and a half of good ground had been sown about the end of March, in a promising season, with French Beans at 2 feet apart, the grower being determined to be early. All seemed to prosper well for eight days, and the seeds had swollen nicely, when cold wet weather set in and the entire crop was lost; but the ground was immediately planted with Walcheren Broccoli, so the loss after all was not so great. Successional sowings are made every fortnight or three weeks, until the end of June, by some growers, but most of the large growers sow their French Beans about the 8th and 20th of April, the first and last week in May, and the first week in July, the Scarlet Runners occupying the interval. The last sowing consists chiefly of the Negro, and just yields a nice crop of young and fine pods before being destroyed by frost; whereas, were they sown a fortnight later they would be apt to be nipped when coming into bloom. French Beans are, likewise, sown along both sides of Asparagus ridges containing two or more rows in April, in single rows about 6 or 8 feet apart, with Custard Marrows grown between them; and in rows 3 feet apart, with two rows of Shallots or Onions occupying the intervening alleys. Some growers sow late crops in rows 4 feet apart, and plant two rows of Coleworts in every intervening alley. Before the seeds appear, the soil immediately over the seeds is gone over and slightly loosened with an iron-toothed rake, so as to permit of an easy egress of the seedlings. When sown in bare fields, even though Lettuces be planted amongst them, a little ridge of soil is frequently drawn to the north or windward side of them as an additional protection from cold winds. Whilst the plants are growing, they are rigidly attended to as regards keeping clean and hoeing the soil, and when they reach 4 inches in height they are earthed up a little. The catch crops, too, are cleared away as soon as they are ready, in order to give the French Beans every opportunity of a healthy development, as they are reckoned a very remunerative crop. Those grown in frames come into bearing in June, just according to how they are treated and last in good picking condition for six weeks; and those in warm borders begin to fruit in the last week of June or first week in July, and continue to yield a fair crop for nearly two months in a moderately moist season, and if closely picked. The first main crop immediately follows the border ones, and as a rule lasts the longest. Drought makes them short-lived sometimes, but in rich soils and warm moist seasons, the yield is so heavy, that it is scarcely possible to pick them as quickly as they grow. Drought too, induces red spider, with which I have seen half-a-dozen acre fields completely overrun; and, although this pest is very prejudicial to the health and longevity of the crop, there is no remedy for it. The Beans are gathered by women, who put them into half-sieve baskets, which they empty when full into larger ones; or they may put them at once into large ones, which, when full, they carry on their heads to the end of the rows, where to leave them to be carted home, where they are washed to remove the grit. They are then packed into round half-bushel vegetable baskets, which are covered with Rhubarb leaves fastened down with withes, and piled one above another on the waggons that convey them to market three times a week. The market gardeners, as a rule, save their own seeds, and a piece of the first or second main sowing is generally selected for this purpose. The plants in the rows to be saved for seeds are first subjected to two or three pickings for market; then they are left untouched until they are fully ripe, when they are pulled up by the roots, tied into little bundles, which are slung in pairs across a fence or rail to dry. Sometimes, too, the haulms are spread over sashes to dry, and in the event of wet weather they are strewed under some spare sashes, where they get well dried without

receiving any of the rain. I have sometimes seen them spread out over a series of sashes resting on frames, and other sashes laid over them again, and tilted up at back and front so as to permit of a free current of air, and here they dry readily. They are then safely housed until wintry weather sets in, when they are threshed, cleaned, and stored in rough brown paper or canvas bags, or placed in drawers, or the corner of a loft, until sowing time again arrives.—*Fitch*.

THE BEST DWARF FRENCH BEANS.

The following are all useful for forcing purposes, or for the first outdoor crop; but they should be grown for such purposes only, as they are, both in size of pod and quality, less meritorious than good second-early or main-crop kinds:—

Osborn's Early Forcing.—Dwarf and compact; flowers, flesh-white; pods, short, very plentiful; ripe seed, medium length, plump; in colour, buff, heavily marked with dark red.

Williams' Early Prolific.—Dwarf and compact; flowers, large, pale mauve; pods, medium length, flaked with purple, abundant; seed, rather short, plump; in colour, buff, spotted black and red.

Dell's Kidney.—This variety seems to be in every respect an exact duplicate of Williams' Prolific. The flowers are the same, pods the same, and habit the same; but there is considerable difference in the character of the seed, which is short, round, thick, and dun-coloured.

McMillan's Early Prolific.—Another duplicate of Williams' Bean in growth, colour of pod, and of seed; but, singularly enough, the flowers differ, being of a pinkish white colour.

Carter's White Advancer.—Medium growth, less branching than the previous ones; pods, rather longer, pale green in colour; good when very young, but thickens quickly; flowers, white, good average cropper; seed, medium length, plump; in colour white. This is a good first early outdoor kind.

Yellow Canterbury.—Tall and erect in habit, pods, medium length, very freely produced; flowers, flesh-white; seed, small liver-coloured; a good outdoor first early.

Menier's First Early.—Tall and compact in habit, pods, medium length, average cropper; flowers, flesh-white; seed, nearly round, pale buff; a very good first early.

Salmon Mexican.—Stout and compact, flowers, flesh-white, pods of good length, a large cropper and of excellent quality; seed, rather long, of average size; in colour pale salmon-buff. A capital second early variety.

Newington Wonder.—Compact in growth, but with a great tendency to run at the points; flowers, lilac; pods, small, abundant; seed, very small, flat, and in colour brownish-white. This variety is one of the very latest; it is inferior to some of the other kinds.

Long-podded Negro.—Vigorous and branching; flowers, pale mauve; pods, of good length, very freely produced; seeds, flat, long, and black in colour. A most excellent main crop variety.

Cutbush's Giant Dwarf *alias* **Long Red Flageolet.**—Tall and erect in habit; pods, long, of good shape and of excellent quality, abundant; flowers, flesh-white; seed, long, large, dark red. A fine main crop kind, and valuable for show purposes.

Exhibition Dwarf, *alias* **Wilson's Wonder**, *alias* **Victoria Dwarf.**—A very distinct kind; habit, tall, branching; flowers, white; pods, very long and thin, of first-rate quality, and freely produced; seed, longish, thin; in colour, buff-white, with small black spots next the eye. This is a very fine late kind, valuable for main crop and for exhibition.

If I were asked to name six kinds out of this number suitable for general garden work, I should name Osborn's Bean for forcing, Carter's White Advancer for first sowing out-of-doors, to be followed by Salmon Mexican, Negro, Cutbush's Giant, and Exhibition Dwarf. Pods that have dark-coloured flakes upon them are, I think, objectionable. A. D.

New Potatoes at Christmas.—For many years past I have always managed to have a few new Potatoes for Christmas. This I effected some twenty years ago by saving a few old tubers until September when they more resembled pieces of sponge than Potatoes. I then placed them in layers among damp leaf soil, when they threw out Potatoes from the eyes, instead of foliage, but the Potatoes were anything but good. After that I planted outside in July, covered up with long litter when frost set in, and dug Potatoes from open quarters; but, I must admit, that the disease often caught us napping. For these six years past, however, I have pursued the following plan and have always had new Potatoes in abundance at Christmas. After I get clear of early Melons, I dig up the soil and mix it with leaf mould, and plant old seed saved from last year, the best variety for the purpose being the Lapstone. I place the lights on the pit, tilting up both ends with bricks, so as to allow a free circulation of air. I give only one good watering, and the result is new Potatoes equal in size and flavour to those grown naturally outside. When the tops die off, I cover the haulm with dry litter and replace the lights, to keep out frost.—R. GILBERT, *Burghley*.

MOOR PARK.

THERE are but few great gardens within a short distance of London that are better worth a visit than those at Moor Park, while the old historical associations of the place give it an additional charm. The park itself consists of about 500 acres of gently undulating ground, and this diversity of surface makes one think that it is much more extensive than it really is. It contains some splendid old Pollard Oaks, with rugged trunks, varying from 20 to 30 feet in circumference, the tops being as fresh and as healthy as in specimens only a century or two old. Of the Scotch Fir, too, one of the most characteristic of trees for park or woodland scenery, there are some fine specimens, with enormous stems and great flat heads. They are judiciously planted in clumps or irregular masses, and so treated, have a far more striking effect than when dotted indiscriminately all over a domain, so as to become monotonous. The rising ground in the park affords capital standpoints, from which extensive views of the surrounding country may be obtained, more especially of Harrow and Watford. The pleasure grounds were laid out by "Capability Brown," and slope gradually from the park to the mansion, which stands on a spacious plateau in the valley. The lawn is pleasingly diversified by some splendid Conifers and masses of Rhododendrons, that have long ago outgrown their original boundaries, and now ramble unrestrained over the fresh velvety turf. Masses of dark glossy-leaved Portugal Laurels, judiciously interspersed, here and there, also give to the whole a pleasing appearance; of Cedars of Lebanon there are also some remarkably fine examples, and a Spruce Fir is said to be one of the oldest and largest in the country; it has several massive trunks forming in themselves a little grove, the roots rambling over the surface of the ground, interlacing and forming in some places a perfect network. At a distance of several feet from the main trunks of this little Fir grove, another young tree has started up from one of the large exposed roots, and this promises to equal its associates in size in a few years time. Looking at the mass of interwoven roots and the group of trunks, old and young, to be found here, one is irresistibly reminded of the Banyan tree, which, by means of stem-roots, soon covers large spaces of ground, to the exclusion of other kinds of vegetation. *Pinus Pinsapo* does remarkably well here, one specimen of it being close on 50 feet in height, a perfect pyramidal mass of fresh glaucous foliage from top to bottom. In localities where this prospers it is one of the most attractive of all Conifers, and well deserves a place in the most select collection. The drooping variety of the Lawson Cypress forms a graceful specimen here along with the erect normal form. Adjoining the flower garden, which has been most effective even this dry summer, is an extensive and beautifully kept croquet lawn, which is not only admirably adapted for the purpose for which it has been specially constructed, but also furnishes a cool fresh expanse of mossy turf, than which few things contribute more to our enjoyment of a garden. The fine appearance of this broad velvety natural carpet is still further enhanced by a luxuriant hedge, formed entirely of the common Sweet Briar or Eglantine, which cuts it off on two sides from surrounding objects. At the time of our visit the fence was one dense mass of fresh young growth, profusely studded with delicate pink flowers and unopened buds. A Rose fence, or hedge of Sweet Briar, should certainly find a place in every garden; for, when once well planted, they give but little trouble, and are almost certain to succeed, especially on deep rich soils. The kitchen and ball-room, which are partially detached from the mansion, jut out on to the lawn. Instead of being obtrusive, however, they have actually been made most attractive, the walls and roof being wreathed with Ivy, Virginian Creeper, Roses, and other graceful climbers, in such a way as to conceal all architectural details. A terrace at one extremity of the lawn overlooks an attractive wild garden, in which is caught delicious glimpses of natural wildness, in contrast with much that is more kempt and trim. In this sheltered spot are cool winding walks that meander amid Ferns, Heather, Grasses, and Great St. John's Wort, the great golden flowers of which shine like golden chalices amid the deep-green foliage by which they are surrounded. Great Scotch Thistles rise here in native luxuriance, and the gracefully pendent plumes of *Carex pendula* sway to and fro with the slightest

breeze. This is a native plant far too seldom seen in our gardens, a fact sadly to be deplored, as when planted by the moist spongy margins of ponds and streams, it forms an object of as much beauty and grace as the most delicate exotic. In another part of the grounds, between the terrace and the flower garden, a fine broad sweep of fresh mossy turf is nearly over-shadowed with Elms and other shade-trees, with here and there a fine large-leaved Catalpa, or a glossy-leaved purple Beech, to break the monotony of the surrounding green-tinted foliage.

The kitchen gardens are a considerable distance from the mansion, and are nearly 10 acres in extent. Moor Park is notably a fruit-growing place, and it was here that the Moor Park Apricot, one of the best varieties in cultivation, originated. The Vineries and Peach-houses are well stocked with healthy Vines and trees, most of which were bearing abundant crops of splendid fruit. When we saw them, the early Vinery and Peach-houses were over, all the fruit having been gathered; the trees were, however, not left unattended to on that account. This is the great secret of good culture; any ordinary cultivator will attend to a tree or plant in fruit or flower, but how often do we find them left to the ravages of thrips and red spider directly the last fruit is gathered, and just at the time when the partially-exhausted tree requires extra attention to enable it to recruit its energies for the production of next year's crop. A long glass wall here serves the double purpose of Peach and orchard-house, and most of the small standard trees of Plums, Apricots, and Cherries, were bearing heavy crops of fine fruit. These appliances are extremely useful to a gardener, more especially in cold exposed northern districts where, all through the winter, they can be utilised for the preservation of different half-hardy plants and vegetables, which invariably suffer if fully exposed. The Vineries are in part heated by old brick flues; but, notwithstanding this drawback, fine crops of large well-coloured bunches of Grapes are obtained annually from them. In one of the Hamburg-houses a Vine of the Gros Colman bore thirteen fine bunches. This is a remarkably fine Grape in appearance, and a Vine or two of it should find a place in every establishment. The Muscat-house is heated with pipes, and the Vines are bearing a good and even crop of fine well-coloured bunches. Peaches were this season of excellent quality, and one of the houses, just at its best, contained Princess of Wales, Noblesse, Royal George, and other standard varieties, models of successful cultivation; while Figs do well trained along the back walls. Of Pines some nicely-swelled fruit were ready for cutting at the time of our visit. In the kitchen garden Peas, Cauliflowers, and other vegetables were abundant and of excellent quality, while Strawberries and other small fruits were producing immense crops.

Hampstead Heath.—It is now some two or more years, says Dr. Laukester, since London became possessed of Hampstead Heath, yet, with the exception of the fact that a large number of persons around the Heath have claimed and enclosed little bits of it, nothing has been done. The inhabitants of London should remember that they are now the possessors of this picturesque bit of land, and should do what they can to make it an agreeable place of resort for all classes. As far as I can see this fact has been quite overlooked. The first thing necessary to make Hampstead Heath a healthy place of resort is to have it drained. From its undrained condition it is positively in many parts malarious. Neuralgia, rheumatism, and diseases produced by undrained land are frequent amongst the inhabitants on and around the Heath. One of the wealthy inhabitants of the Heath has offered the Board of Works £1,000 to enable them to drain that part of the Heath around his house. The ponds on the Heath are gigantic nuisances. Now what is really, at present, so dangerous might be converted into a great boon for health. These ponds might be made into baths; Hampstead Heath is a favourable situation for such an institution. The North London, Metropolitan, and Midland Railways have all of them stations near the Heath, and tens of thousands from the City, Islington, Marylebone, and St. Pancras would gladly avail themselves of an opportunity of bathing on the Heath. Let the South Hill Pond be at once filled up, and the ponds known as "Two" and "Three" should be cleaned and concreted at the bottom, and a fresh supply of water obtained. These ponds should then be walled in, and proper accommodation provided for bathers. The walls need not be ugly, but ornamental, and trees and shrubs planted outside, to add to their agreeable appearance.

WILHELMSHÖHE.

THE palatial villas of the lesser princes of Germany were frequently erected in emulation of the palaces of the greater potentates of Europe, and sometimes rivalled, if they did not exceed in dimensions and magnificence, the models from which they were taken. They were, indeed, very often quite out of all proportion with the extent of the electorate, or landgravate, or principality of whose sovereign ruler they formed the state residence. Wilhelmshöhe is one of the most remarkable of the State residences of the Germanic reigning princes, and was celebrated as a noble residence, erected at enormous cost, long before the attention of the present generation was attracted to it, as the palace-prison of the late Emperor Napoleon III. It was founded by the Landgrave Moritz in the seventeenth century, and its situation among the woods which clothe the heights to the west of the handsome little city of Cassel,

especially as seen from between the columns of Ionic portico, greatly adds to the beauty and charm of the more distant objects. The designing of the artificial lake and islands certainly does credit to the whole succession of landscape gardeners who have gradually brought them to something like their present state; for the detached trees, such as those which form the foreground of our engraving, and other plantations, in which fine Conifers play a conspicuous part, help, with the lake and islands, to make a very graceful picture, in which the palace, which has no great merit except that of being built with a very beautiful white stone, plays but a secondary part; the gardeners' work having been, on the whole, far more successful than that of the architect. The great want which is strongly felt on a visit to Wilhelmshöhe is the presence of flowers, which may be antithetically said to be "conspicuous by their absence." There is not, in fact, so

Wilhelmshöhe.

sufficiently indicates that it was originally designed as a hunting seat, just as, in somewhat similar situations, the château of Compiègne and Versailles were by Louis XIII. of France. The woods about Wilhelmshöhe, at the time the site was determined on, abounded with all kinds of game, especially wild boars, of which the modern Westphalian hams still afford evidence. The situation is, in many respects, really magnificent; the height of the ground, above the valley of the Fulda, being more than 1,300 feet. The views commanded from the terrace and the principal apartments to the east, are, consequently, very fine; and, from the nature of the country seen over, very extensive, ranging for nearly five and thirty miles beyond the pretty little city of Cassel, which is situated in the plain. The nature of the scenery thus seen is extremely varied in character, exhibiting finely contrasting expanses of woodland and open country, as well as extensive ranges of hills and far-spreading plains. The foreground to the extensive prospect which the lofty terrace commands,

to speak, a single flower bed to cheer, even with a solitary mass of colour, either the western terrace or the lower ground beneath; nor are the fronts of any of the plantations anywhere lighted by those flashes of flower-colour, which, in analogous situations, often produce such artistically charming and rich effects. Till quite recently, the gardens of Versailles, and those of nearly all the great French châteaux, were open to a similar objection; but, happily, the love and knowledge of flowers has increased so rapidly of late years that in a very short time not even the cottage of the artizan, any more than the palaces of a landgrave will be open to the objection that it is without flowers. The western front of Wilhelmshöhe commands a view of the formal and extensive gardens, which are of the school which the last century delighted in. There is a grand series of waterfalls and fountains, with one especially grand cascade, the whole of the display being supplied from an aqueduct of fourteen arches, which are combined with a complicated series of hydraulic engineering work on a scale

only second to that of Versailles; and, barring the lavish addition of sculpture, which is not altogether wanting at the landgravean palace of Wilhelmshöhe, the effect produced is almost as striking. It is certainly superior, in a general character, to the cascades of St. Cloud, the machinery of which is still intact, though the palace is destroyed. The Westphalian palace of Wilhelmshöhe is, in fact, well worthy of the study of a landscape gardener: for, to be a complete master of that difficult art, the methods of past schools must be as carefully studied as the more familiar principles in practice at the present time. This is not the place to enter upon the historical associations of Wilhelmshöhe: but it should be noted, *en passant*, that it was possessed by a Bonaparte, in the character of master, sixty years before it became the abode of another of that family as a state prisoner. When Western Germany was overrun, during the first Empire, the kingdom of Westphalia was established, and Jerome Bonaparte, the ephemeral king of an ephemeral kingdom, resided, during his brief term of kingly dignity, at what was then called the *royal* palace of Wilhelmshöhe. H. N. N.

THE ARBORETUM.

SEA-SIDE PLANTING.

By W. GILCHRIST.

SOME extensive plantations have recently been formed, both in England and Scotland, on barren tracts within the influence of the sea-breeze; and our Continental neighbours have also taught us a great lesson in the indomitable perseverance with which they have overcome so many difficulties and succeeded in the planting of barren tracts and sandy wastes, where the soil was of the poorest description, and considered altogether unfit for the growth of any vegetable product. The providing of artificial shelter by forming screen-fences, sowing tree seeds, and then thatching the ground with branches; or sowing Broom or Whin seeds along with the tree seeds, so as to shelter the seedling plants, have been some of the chief causes of success, especially where the soil was light and inclining to drift-sand. About five years ago, on the west coast of Ayrshire, I saw a plantation on soil of this description. It consisted chiefly of Scotch Pine; where it was fully exposed to the blast there was not half a crop of trees on the ground, and these were either drifted up with sand, or their roots were left almost bare of soil. The trees appeared to be about ten years old, and what of them were growing appeared to be in a healthy condition. Had screen-fences been erected on the exposed parts of this plantation, there is no doubt but they would have prevented the sand from drifting so much, and the plantation would by this time have been providing shelter to the adjacent lands, and forming a very prominent object in the landscape. The soils along some parts of the sea-coast are sometimes found to be very suitable for the growth of trees and shrubs, and in such places there is little difficulty in growing any of the hardy trees, and even some varieties that do not stand the frost inland are found to grow well along these favoured shores; especially is this the case along the shores of Inverary, Lochgilphead, and Loch Fyne. This is principally owing to these places being sheltered from the cold western blasts of winter and spring by the range of hills lying between them and the main ocean. One of the most difficult situations for the formation of a plantation on the sea-coast is to be found where the ground is low lying, or rising from the shore with a gentle slope, and at the same time exposed to the full force of the ocean breeze. The difficulty can only be overcome by erecting screen-fences at such distances as will effectually break the storm and provide shelter for the young plants. These screen-fences should be erected with brushwood; the thinnings of young plantations, Broom, Furze, or anything of that description, that will make the fence open and allow the wind to pass through it, instead of passing over it, as in the case of turf or stone dykes. Some of the cheap and hardy varieties of underwood, such as the common Elder, sea Buckthorn, Willows, Sloe, Thorn, common Whin, &c., should all be used. Of course, where these or any variety of underwood is found growing naturally, full advantage should be taken of it; but where there is none, it must be provided and planted at from 2 to 2½ feet apart, so as to act as nurses to the young trees which may be planted at the ordinary distance apart. This underwood, though absolutely necessary for a number of years at the first outset, must be always kept in check, so that the trees may have full scope for the development of both root and branches. If the soil is light, with a gravelly bottom (as is often to be found on the west coast of Scotland), or dry barren sand, the kinds of trees

to be planted must be principally of the Pine tribe, such as the *Pinus pinaster*, *P. montana*, *P. austriaca*, *P. Laricio*, and Scotch Pine. Where the soil is loam or peat, with a mixture of sand, and the sub-soil inclining to clay, the broad-leaved trees may be used, such as the Birch, Elm, Pine, Alder, and Norway Maple. All these varieties of trees mentioned have been thoroughly tested along the shores of the west of Scotland, and, if properly taken care of, they will in due time form valuable timber trees for which a ready market and a high price can at all times be had. In an exposed situation, such as has been described, where the trees are planted near to maritime residences, chiefly for ornament and shelter, besides the varieties mentioned, some of the ornamental trees and shrubs may be used, such as the Laburnum, Mountain Ash, Oak, Ash, and Beech; and for shrubs, the Ribes, Sea Tamarix, Hazel, Elder of sorts, Snowberry, Privet, and common Lilac. When these have succeeded so as to provide shelter, some of the evergreens and finer sorts may be introduced. To provide shelter for these maritime residences, hedges will be found to be better than stone and lime walls; that is, unless the walls are higher than what it is intended for the trees or shrubs to grow. I have often observed that where the trees grow a few feet higher than the wall, the tops of them grow freely and are regularly furnished, while the branches parallel with the top of the wall appear as if a portion of them had been cut away. This is caused by the blast striking against the wall in full force, the wall being a resisting body through which wind cannot pass, it ascends to the top of the wall with increased velocity, and the higher the wall the greater is the force at the top, and of course its influence on plants is the more destructive. Screen-fences, composed of Brushwood, near to a residence have a bad appearance, and at the best are only temporary; but I have seen them used with good effect during the most severe winter and spring months. As before mentioned, the most effective shelter and fence for these residences is a good hedge, viz., a sunk wall or fence with the back sloping inwards, and a hedge on the top planted with Sea Buckthorn, Beech, Elder, or Blackthorn. These hedges do not altogether resist the sea-breeze, but they tend to prevent it striking with so great force on a given point, and the salt spray is very much exhausted before it passes through a good hedge, and by that time will do no harm to any of the maritime plants. Where the elevation rises abruptly from the shore and terminates in flat or table land, even though the situation be as fully exposed to the blast as the one previously described, there is little difficulty in forming plantations; for as soon as the harder varieties of plants can be got to grow on the exposed side, so as to provide shelter, any sorts of trees that are suitable to the soil will grow, as the temperature is generally higher in these situations during the winter and spring months than it is in the inland districts. In regard to the exposure of trees to the influence of the sea-blast, I consider that it is not the blast or sea-breeze, but the sea-air that is so damaging to the trees during the winter and spring months. Climatic influence acts on the vegetable kingdom as well as on the animal, and it is no uncommon thing in exposed districts of the west coast, during the prevalence of westerly and south-westerly gales, to see the windows crusted with salt like frost. When salt is in the air in such quantities as to leave its impression on the windows, it must of necessity be very damaging to the constitution of trees and shrubs. It is well known that salt used in moderate quantities is a very efficient manure, but if overdone, nothing is more damaging to vegetable life.

Causes of Failure.

In speaking of the formation of plantations on the sea-coast, reference has often been made to the failure of the plants that were planted by a very enterprising gentleman on one of the islands of the Hebrides. But too much stress should not be laid upon the failure of that undertaking, as it was done under very adverse circumstances, and at a time when the formation of plantations was not so well understood as they are at present. The undertaking has been a success, in so far as it has proved that some trees will grow under the climatic influence of the ocean; and I have no doubt that, had the formation of this plantation been more judiciously and carefully done, it would by this time have been one of the monuments of arboricultural triumphs on the sea-coast. Some of the causes of failure may be here mentioned, such as the unsuitableness of the soil for the growth of any trees, a great part of it being deep Moss, combined with a humid atmosphere, which keeps the soil always in a damp and spongy state. Yet, in that soil and situation, *Pinus pinaster*, *maritima*, and *montana*, trees that are said to grow best in light sandy soil, not only kept in life, but for a number of years after being planted appeared to be in good health. Of course none of the plants, except what are on the sides of ravines or some sheltered spots where the soil is more congenial, will ever come to be timber trees; but if they grow so as to provide shelter for the growth of timber trees, a great end will have been gained. Another cause of failure was

the extent of the undertaking for one season. The formation of the plantation should have extended over a number of years, beginning with the most exposed parts, and planting such trees and shrubs only as would provide shelter. As soon as shelter was thus obtained, the remainder could be planted, and even some useful timber trees might be introduced into the exposed parts, as they would then be sheltered by the shrubby sorts that were formerly planted. In the absence of this system, screen-fences ought to have been adopted, irrespective of the extent of the plantation. The packing and shipment of the plants in so large a quantity would also be against their future success; for it is a well-known fact, that even in the most favourable districts for growing plants, the shorter time they are out of the nursery ground before planting the better. Acclimation also exercises a very great influence on plants, whether they be planted inland or along the shores; but more especially would the influence of acclimation be felt on an exposed coast, or a bleak and barren island, where the soil, even at the best, cannot be said to be suitable for the growth of trees. In such a situation, to be successful in the formation of plantations, a home nursery must be established, and the plants grown from seed.

Best Sea-side Trees.

In a report on sea-side planting, for which the Highland and Agricultural Society awarded their gold medal, special reference is made to plantations that have been formed on the northern extremity of the county of Norfolk, at an altitude of from 200 to 500 feet above the level of the sea. The surface is reported as generally being poor, and the sub-soil a hard ferruginous gravel. The plants used were Goat Willow, Alder, Birch, Sycamore, Scotch Elm, and two varieties of the *Pinus Pinaster*. The formation of the plantation, including planting and fencing, is reported as having cost upwards of £10 per acre. The success of the undertaking is attributed to the preparation of the ground by trenching 18 inches deep; erecting screen-fences of Brushwood, &c., 6 feet high; carefully preparing the plants, having them well furnished with fibrous roots before planting; and having the ground cleaned by hoeing for the first two years after planting. The cost of the formation of these plantations appears to be very high when compared with plantations formed on the north coast of Morayshire by Mr. Grigor, and reported by him as having cost £232 18s. 7d. for 298 acres; or, on an average, rather less than 16s. per acre. The plants used were Scotch Pine and Larch. However, the writer states that the unusual small expense of these plantations was owing to "the ground being soft, with little or no surface herbage, rendered it suitable for small plants, which were planted by the hand-iron, by people in the vicinity much practised in the work, and who could plant an acre each daily on such ground without difficulty. The plantations were also made at a time when the price of nursery plants was under the usual rate," and also that "the expense of fencing these plantations was very small." In specifying the kinds of trees and underwood best suited for planting within the influence of the sea-breeze, our remarks must be understood as being chiefly applicable to the west coast of Scotland, and none will be recommended but what have been thoroughly tested, either along the Ayrshire coast, the shores of Campbeltown, or on the islands of Arran and Bute; and first amongst these, the palm of honour must be awarded to the *Pinus Pinaster* and its varieties. This tree was introduced in 1593, and is common throughout Europe and the shores of the Mediterranean. It is generally found in plains near to the sea, and on sandy soils of the poorest description. It has been successfully grown on the coast of Galloway, and on the northern coast of the county of Norfolk, where, as Mr. Grigor, in his "Arboriculture," states that "some of the best specimens of the tree in Britain are to be found standing nearly 80 feet high, with trunks 12 feet in girth. Many such trees stand at Westwick Park, where few other species of trees would become timber." It has also been most extensively used by our Continental neighbours in the successful formation of plantations on the sea-coast, and on large barren tracts of drift-sand, where, previous to its cultivation, scarcely any plants of a ligneous nature could be found to grow. Its accommodating nature in regard to soil and situation was also distinctly proved in the success that has attended its introduction to some of the islands of the Hebrides, where, under very adverse circumstances, and in soil entirely uncongenial to its nature, or, at best, very different from that of its native habitats, it has shown such symptoms of success as will ensure its further introduction at no distant period. On the Continent of Europe its wood is principally used for the production of resin, tar, and turpentine, and for the ordinary kinds of carpentry and fuel. The *Pinaster* has a very strong tap-root, which, in loose, dry, sandy soils, descends perpendicularly into the ground, seeking its nourishment and fixing its anchor or stronghold in a strata that is not reached except by some of the broad-leaved trees. This is a peculiarity which makes it, unless frequently removed in the nursery lines, very difficult to transplant successfully;

but this very peculiarity is what makes it, above all others of the Pine tribe, a suitable plant for barren sands and sea-side planting. It grows very fast; but is rather loose in its habit, and is very often "kneed," or blown a little to the one side; but it very rarely occurs that any of them are uprooted by the storm. One of the varieties of this tree—*Pinus Pinaster* minor, or *P. p. maritima*—is said to be hardier than the species. It is chiefly distinguished by the smallness of its cones and the shortness of its leaves, as compared with the other. It is found growing on the Continent along with the *P. Pinaster*. The next in order of rank amongst the Pine tribe are the *Pinus montana* or *Pumilio*, *P. sylvestris*, *P. austriaca*, and *P. Laricio*. The *P. montana* is of a low-spreading bushy habit; a native of Europe; abundant on the Alps, Pyrenees, and other high mountains; was introduced in 1779. It stands the exposure of the sea-breeze; but is of little use except to cover the ground so as to produce shelter for the more useful plants. It prefers a dry soil and a high altitude, but will grow on Moss, or on calcareous or chalky soils, and at a higher and more exposed altitude than any of the other Pines. The Scotch Pine, *P. sylvestris*, is also very accommodating as to soil and altitude. The merits of the Scotch Pine are so well known amongst arboriculturists, that they do not require to be set forth in a paper of this kind. The *P. austriaca*, while growing freely on light sand or gravelly soils, will also grow well on wet or heavier soils than either the Scotch Pine or the *Pinaster*. However, it prefers a deep dry, calcareous sand and a southern exposure. The *austriaca* was introduced from the Bretnia forest of Austria in 1835, and is a free-growing noble tree. It grows freely along the shores of the Firth of Clyde, and many noble specimens of it are to be seen throughout England. For producing shelter or forming a dark background in the landscape, it is unsurpassed. When allowed to grow in an open situation, its branches are wide-spreading and very picturesque. Its timber is strong, tough, and resinous, and in its native country is said to be valuable for resisting the effects of change from moisture to dryness. If this characteristic holds good of its timber grown in this country, it may yet come to be valuable as material for railway sleepers, &c. But for this purpose it is said to be surpassed by the *Pinus Laricio*, one of the most valuable and fast-growing Pines that has yet been introduced. Although introduced in 1759, it has not been so thoroughly tested on the sea-coast as the other Pines we have already mentioned; but wherever it has been carefully planted there it has given satisfaction. Being a native of the island of Corsica, where it frequently attains the height of 110 feet, it will, in course of time, be regarded as one of our best maritime plants. It is very difficult to transplant, and requires a good, open, loamy soil to ensure success. The wood of it is soft and easily wrought, of a whitish colour; the heart-wood is darker, and is found to be of very great duration. It is used by the French Government for ship building, and other favourable circumstances, is fit for masts for the navy in thirty or forty years. I have not seen the Corsican Pine planted to any extent along the sea-coast; but specimen plants of it are to be found growing within the influence of the sea-breeze in different parts of the Ayrshire and Wigtonshire coasts, and also on the shores of Campbeltown. The Larch (*Larix europæa*), Silver Fir (*Picea pectinata*), and Norway Spruce (*Abies excelsa*), are sometimes found growing remarkably well within the influence of the sea-breeze, but they cannot be relied upon unless sheltered by other trees. In fact, the Spruce, though growing within the influence of the sea in its native country, seldom attains even to mediocrity in the west of Scotland when exposed to the sea blast. The American Spruces, *A. nigra* and *A. alba*, are more to be depended on, but they do not come to be so useful timber trees. Where the soil is suitable for hard-woods, the Larch may be grown profitably amongst them; but on exposed sandy soils it will not succeed. The same may be said of the Silver Fir; but wherever a suitable situation for either of them can be got they should be introduced, as there are some fine specimens of them along the Firth of Clyde, and they soon come to be profitable trees when grown in a suitable situation. We have given the preference to the Pines for planting within the influence of the sea-breeze, both for shelter and profit; but it cannot fail to be observed that the broad-leaved or hardwood varieties of trees form the greater part of the plantations along the west coast of Scotland and the islands we have mentioned. Conspicuous amongst these, and growing where there roots are sometimes submerged in salt water, are the Sycamore (*Acer pseudo-Platanus*), a native of Switzerland, which withstands the sea-breeze better than most trees. It is rarely known to grow one-sided, even in the most exposed situations, where it is often seen standing alone. The Norway Maple (*A. platanoides*) is a native of the west coast of Norway and the shores of the Baltic, where it attains large dimensions, growing close to the sea-shore. The Scotch Elm (*Ulmus montana*), when exposed to the sea-breeze becomes a low-spreading tree, of little value for timber, but produces good shelter, and will thrive in almost any sort of soil that is not water-logged. The Alder (*Alnus glutinosa*) is specially

adapted for growing in the wet and marshy places along the shore. It stands the sea-breeze well, and has been used as a nurse in dry situations; but for this purpose it is surpassed by *A. incana*, the hoary-leaved Alder, which forms a very handsome tree, and will grow in either dry or moist soils. The Birch (*Betula alba*) is one of the most useful trees for growing in exposed situations; but when grown fully exposed to the sea-breeze it seldom attains that graceful weeping form which makes it such a general favourite in landscape scenery. As a maritime plant it is most useful for planting in a dry peaty soil, with a rocky bottom. On the island of Scurba, Birches are growing out of the rocks, where they are fully exposed to the ocean blast. The foregoing (with the exception of *A. incana*, which has been recently introduced) are what we have found to be the healthiest and most suitable trees for growing on the west coast of Scotland, in situations where they are fully exposed to the influence of the sea-breeze; but there are others that are found growing freely in some of the more sheltered nooks. Amongst these are the Beech (*Fagus sylvatica*), common Hornbeam (*Carpinus betulus*), Ash (*Fraxinus excelsior*), and Oak (*Quercus pedunculata* and *sessiliflora*). The two former are well suited for planting in a mass, or forming hedges; but I have not seen them succeed as timber trees when fully exposed to the sea-blast. They are, however, useful for planting as a mixture with other hardwood trees for shelter, as they retain (when young) their leaves during winter. The Ash, when grown in good soil and a little sheltered, form good timber trees, and ought to be cultivated wherever the situation is suitable. The Oak will grow exposed to the sea-breeze; but unless in very favourable situations, it becomes very "scraggly," and assumes a dwarf habit. If the soil is suitable, it may be cultivated profitably as copse-wood. The Willows also grow remarkably well on some parts of the sea-coast; in fact, they are so tenacious of life that they will grow almost anywhere; but they never succeed and become timber trees on the coast, except when grown in the hollow places by the side of the running water. These water "rills" are very common on some parts of the coast; and where they occur, no better situation can be got for the Willows. The sorts best suited for timber trees near to the coast are the Bedford Willow (*Salix Russelliana*), Huntingdon Willow (*S. alba*), and the Goat Willow (*S. caprea*). Besides these, a great many of the dwarf varieties of the *Salix* are suitable for growing as underwood. Some of the Poplars are said to grow well on the sea-coast, but I have not seen such success attend any of them as would warrant their being recommended as maritime plants; however, if they are sheltered and the soil suitable, they will ultimately become profitable.

Underwood.

Amongst the underwood best suited for planting within the influence of the sea-breeze must be enumerated a number of the semi-dwarf trees. I will only give the names of these, dividing them into two classes, viz., those that are suited for the general formation of plantations, and those that, though equally hardy, are by the price that is still charged for them, only suitable for ornamental planting. In the first class may be included the Laburnums (*Cytisus Laburnum* and *C. alpinus*). Mountain Ash (*Pyrus aucuparia*) is one of the most admirable trees for planting as a nurse in exposed plantations: it will grow in any soil and in the most exposed situations, is a free grower, and forms excellent copse-wood. Common Elder (*Sambucus nigra*), Black or Sloe-Thorn (*Prunus spinosa*), Sea Buckthorn (*Hippophae rhamnoides*), which is the best of all deciduous shrubs for standing the sea breeze: it seems quite at home on the shore, and will grow in pure gravel, throwing out its branches to the sea; the Hazel (*Corylus avellana*), common Whin or Furze (*Ulex europæa*), and the Privet (*Ligustrum vulgare*). These, along with the dwarf Pines we have mentioned, will produce sufficient shelter and give a very pleasing appearance to a plantation, as compared with the bare-stemmed stunted-looking trees that are so often to be seen along our shores. The ornamental shrubs for sea-side planting are the Bird Cherry (*Cerasus Mahaleb*), the Tamarisk (*Tamarix*), French Tamarisk (*T. gallica*), common Lilac (*Syringa vulgaris*), evergreen Oak (*Quercus ilex*), Snow-berry (*Symphoricarpos racemosus*), common Holly (*Ilex aquifolium*), Laurustinus (*Viburnum Tinus*), red-flowering Currant (*Ribes sanguineum*), the common Arbor-vitæ (*Thuja occidentalis* and *T. Warreana*). Besides these, specimens of the Araucaria imbricata, Cedrus Deodara, Wellingtonia gigantea, Cupressus Lawsoniana, and Nutkaensis, and others of the same class, are occasionally to be met with growing freely on the sea-coast; but they cannot be recommended except where shelter is provided, either natural or artificial. The Portugal and Common Laurel, *Rhododendron ponticum* and its varieties, are often planted, but do not succeed unless sheltered.

Preparation of the Ground.

Before concluding this paper I would beg to offer a few general remarks regarding the cultivation of plantations on the sea-coast and

islands; and, first, the preparation of the ground. If rank Whins or Heath are growing on the surface, they should be burnt down; Whins one year before planting, and Heath at least two years. This is better than trenching, as the natural Whins and Heath provide shelter for the young plants; only, the Whins must be kept in check, so as not to injure the young trees. Hard, "benty" ground on "links," with coarse herbage, ought to be trenched at least 18 inches deep, and the surface "spit" put into the bottom of the trench. This should also be done a considerable time previous to planting, so that the ground may have time to consolidate. Deep mossy or peat ground should also be trenched, and, if possible, some of the under strata (be it clay, sand, or gravel) brought to the surface. If this is not practicable, sand or gravelly soil should be got and added to the surface, so as to give the plants a fair start. Where the ground is wet, it must be thoroughly drained before planting, as nothing is so injurious to plants as stagnant water. On drift sand or sloping banks, much exposed to the sea breeze, screen fences must be provided. The plants must be well rooted, hardy, healthy, and, if possible, reared in the neighbourhood, and kept as short a time out of the ground before planting as possible. Planting operations ought to be done in the months of October and November, or March and April. In the case of Mossy ground it is absolutely necessary that the planting be not begun before the latter end of March. Where the situation is exposed, plant close and thin, early and often. Prune the hardwood trees when young, so that they may grow compact, and not be liable to have their side branches lashed or broken with the wind. Keep the young trees at all times clear of Brushwood or whatever tends to prevent a free current of air from passing through amongst them. The last is of the utmost importance, for unless trees are grown open and allowed to spread their branches, they will never spread their roots; and when the storm comes in all its fury, they become an easy prey to its ruthless blast.—*Transactions of the Scottish Arboricultural Society.*

Pines and Firs.—1. The Pine and Firs being so numerous, and the timbers of many being known in commerce by such a variety of names, it is difficult to ascertain the trees which yield them. 2. The Scotch Fir yields the red deal of Riga, called the yellow deal in London. Norway Spruce Fir yields white deal. 3. North American Pine, known as such here, as imported from America, has many names there. The North American Pine or Weymouth Pine is called white Pine in North America. Yellow Pine is chiefly employed in the States for house and ship building, and is considered to be next in durability to the southern Pine, which again is called Yellow Pine, Red Pine, and Pitch Pine. The American Pitch Pine or Red Pine, called Norway Pine in Canada and Yellow Pine in Nova Scotia, and many others, yields deals of various qualities more or less used in different districts. 4. The American Spruce Firs are the white, black, and red. The last is sometimes called Newfoundland Red Pine, and employed in ship building. Both it and the Black Pine are exported to England.—C. HOLTZAPFELL.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

The Eucalyptus at Balmuto.—I saw in THE GARDEN the other day (p. 42) a notice of this Eucalyptus, which is growing against the wall of my house. It is, however, certainly not *E. globulus*, but apparently *E. cordata*.—J. BOSWELL SYME, Balmuto, Kirkcaldy, Fifeshire.

The Japanese Quince as a Hedge Plant.—An ornamental hedge, formed of the best scarlet form of *Cydonia japonica*, is very beautiful when in full bloom. Another excellent quality of this plant is its defensive character. When properly trimmed, it forms a good hedge.

Bignonia radicans grandiflora.—I recently saw in the old village of Munster, about five miles from either Margate or Ramsgate, a magnificent specimen of this Bignonia. It covered the south side of a house, and was full of blossom, the flower-heads containing some eight or ten blooms of a handsome orange-red colour. Anyone in that neighbourhood who cares about such things should pay it a visit.—"RAMALHO."

The Burr Oak (Quercus macrocarpa).—This is perhaps the most ornamental of American Oaks. Nothing can exceed the graceful beauty of these trees, when not crowded or cramped in their growth, but left free to follow their own mode of development. Who has not admired these trees in American Burr Oak openings? Their large leaves are dark green above and a bright silvery white beneath, which gives the tree a singularly fine appearance when agitated by the wind. The wood is tough, close grained, and more durable than the White Oak, especially when exposed to frequent changes of moisture and dryness.

The Duke of Edinburgh's Norfolk Island Pine at Malta.—In the garden of the governor's town residence at Malta, which is surrounded on all sides by buildings, there is, we learn from the *Farmer's Gazette*, a magnificent specimen of the Norfolk Island Pine, *Araucaria excelsa*, to accommodate a specimen of which, as most of our readers are doubtless aware, the lofty octagon house at Glasnevin was originally built. The Malta specimen was planted in 1858 by the Duke, then Prince Alfred, and at that time was only 7 feet high. In the brief space which has intervened its growth has been so rapid that it is now a fine specimen, at least 50 feet in height.

"LONG MOSS."

(TILLANDSIA USNEOIDES.)

To the traveller in the Southern States of America no natural object is likely to be more striking than the Long Moss, which, from North Carolina to Texas, drapes the trees of all kinds, but is especially abundant upon those which grow in damp situations. This Moss is sometimes found only here and there in small tufts, but frequently it is in such quantities upon a tree as to appear to fill all the spaces between its branches, and from the lower limbs it hangs in pendent tufts several feet in length, which, as they are swayed by the wind, wave with a certain amount of grace. In localities where the Moss is very abundant, its dull grey colour and general drooping habit produce a very sombre effect. As it grows most luxuriantly in situations, which, from being constantly moist, are unhealthy, it is easy to associate it with disease and death, and in some localities it bears the not very cheerful name of "Coffin Fringe." Though popularly called Moss, it does not belong to Mosses, properly so called, at all, but, strange as it may seem, to the Pine-apple family, the Bromeliaceae. Its botanical name is *Tillandsia usneoides*. The genus was named in honour of a Russian professor, Tillands, and its specific name means, resembling *Usnea*—a long drooping Lichen which hangs from northern trees in a similar manner. Including this, there are eight species of *Tillandsia* in the United States, this being the only slender pendulous one; some of the others have broad Pine-apple-like leaves, 2 feet or more long, with their bases dilated so as to hold water. All the *Tillandsias* are epiphytes—*i.e.*, they grow upon other plants, mostly upon the branches and trunks of trees, but they are not parasites, as they desire no nutriment from the plant to which they are attached; this merely serves them as a resting place, and they are nourished entirely by what the air and the rains bring to them. Some of the South American and West Indian species are valued as ornamental hot-house plants, and are usually grown in pots of *Sphagnum*, a condition which approaches nearly to their natural one. Indeed, our southern species are some of them quite handsome, especially *T. bracteata*, the bright red stems of which bear small purple flowers. The species under consideration, *T. usneoides*, is, as just stated, of a very different habit from the others. Its long branching stems are so slender as to be almost thread-like. They produce leaves at intervals of about 3 inches, which are narrow, recurved, and from 2 to 3 inches long; from the axil of each a branch is produced, which may be terminated by a flower or be much prolonged to form a part of the tangled mass of stems of which each plant

consists. The plant presents one peculiarity, of which we find no mention in any of the descriptions; each internode, or space of the stem between two leaves, forms an open graceful

spiral of about two turns, which adds much to the beauty of the plant, when its stems are separated and allowed to grow singly. Both stem and leaves present a uniform grey colour, which, while the plant is growing, has a greenish tinge; an examination with a glass shows the stems and leaves to be of a light apple green, but completely covered with small, almost transparent, overlapping scales, which give the silvery-grey appearance. The epidermis is readily separated from the central portion of the stem, which is tough, and resembles horsehair in size and appearance. The solitary flowers are borne at the ends of the branches; they have a three-parted calyx and corolla of three petals, which, though not more than a fourth of an inch across, is exceedingly interesting from being of bright gamboge-green colour. The pod is about an inch long, and splits up in such a manner as to look very much like a withered flower. Aside from forming a striking feature in the landscape, the Long Moss is of no little economical importance. The central portion, exceedingly tenacious and elastic, has long been employed as a substitute for hair. The plant is found in Central and South America and the West Indies, and has been put to so many uses by the Spanish Americans that in some localities it is known as "Spanish Moss." The primitive method of procuring the fibre is to place the Moss in shallow ponds exposed to the sun to rot the somewhat fleshy outer covering; it is then taken out and allowed to dry, after which a moderate beating removes the outer portion, and the fibre is left in a black tangled mass, which but for its branching character it would be difficult to distinguish from hair. We learn that since the war several establishments have been erected for the preparation of the Moss in a more rapid manner. The Moss is placed in large tanks, where it undergoes maceration by heat, and after drying is beaten by machinery; this is said to afford a superior product. By itself it forms an excellent stuffing for mattresses, chairs, and the like, and is probably largely used to mix with hair; it forms a considerable article of commerce, and its domestic uses are numerous. In Texas we have seen it twisted and woven into coarse matting, and it is said to be capable of forming excellent ropes and cables. — *American Agriculturist*. [This *Tillandsia* may be seen growing in the succulent house at Kew, on *Cereus rostratus*, a climbing species

Long Moss (*Tillandsia usneoides*).

of Cactus, and it is the opinion of many that it would succeed in the open air in Devonshire and in some of the other warmer parts of England, as in Texas it is often found coated with ice a quarter of an inch in thickness.—*Ed.*]

SQUILLS (SCILLA).

(Concluded from p. 136.)

Sub-genus II.—*Ledebouria* (Baker).

Perianth, rosy-purple or greenish, with strap-shaped segments, joined together for a considerable length at the base, and forming a cup, falcate in the expanded upper half of the flower; filaments, usually in one series, and inserted above the base of the segments; ovary, globose, stalked, usually expanded at the base into a disk; ovules, collateral, always in pairs in the cells; bracts, small, solitary, deltoid.

38. S. Sandersoni (Baker).—Leaves, produced along with the flowers, fleshy-herbaceous, ascending, ovate-oblong, sub-acute, narrowed abruptly at the base, 2 to 2½ inches long, 9 to 15 lines broad, with very numerous snken veins; flower-stems, 2 to 2½ inches high; racemes, roundish, somewhat dense, containing from twelve to twenty flowers each, and 9 or 10 lines in diameter; most of the flowers are abortive; pedicels, 3 or 4 lines long, the lower ones nodding; perianth, roundish bell-shaped, 1½ lines long, of a deep rosy-purple colour, with strap-shaped segments, one-third of a line broad, distinctly streaked with green on the back, and falcate in the expanded upper half of the flower; filaments, thread-like, of a rosy-purple colour, and 1 line long; ovary, globose, stalked, with a discoid expansion at the base; style, thread-like, half a line long, deeply coloured. Cape of Good Hope, in the Transvaal district.

39. S. revoluta (Baker).—Bulb, globose, multiplying abundantly; leaves, five to nine in number, fleshy-herbaceous, spreading, produced along with the flowers, oblanceolate, spoon-shaped, acute, gradually narrowed at the base into a short channelled foot-stalk, 2½ to 3 inches long, 6 to 8 lines broad, green and somewhat wrinkled on the upper surface; flower-stem, central, very slender, flexuose, 3 to 6 inches high, at first nodding at the apex, coloured at the base; racemes, oblong lance-shaped, loose, containing from twelve to thirty flowers each, and, when fully expanded, 2 or 3 inches long, and 12 to 15 lines broad; pedicels, patent, the lower ones 6 to 8 lines long; flowers, nodding; perianth, roundish, bell-shaped, 1½ lines long, of a deep rosy-purple colour, with strap-shaped segments, half a line across, streaked with green on the back, falcate in the expanded upper half of the flower; filaments, thread-like, rosy-purple, 1 line long; style, thread-like, deeply coloured; capsule, globose, stalked, with a discoid expansion at the base. Cape of Good Hope; formerly much grown in European gardens, but now apparently lost.

40. S. minima (Baker).—Bulb, elongated-ovoid, 3 or 4 lines in diameter, the outer coats membranous and lengthened at the apex; leaves, produced along with the flowers, fleshy-herbaceous, ascending, green, smooth, linear, acute, 12 to 18 lines long, 1 to 1½ lines broad; flower-stems, one to two in number, very slender, flexuose, 1 or 2 inches long; raceme, oblong, somewhat dense, containing from twelve to thirty flowers, and, when fully expanded, 1 inch long and 5 or 6 lines in diameter; pedicels, 1½ to 2 lines long, sub-patent, the lower ones nodding; perianth, roundish, bell-shaped, 1 line long, of a deep rosy-purple colour, with segments 1¼ lines across, broadly streaked with green on the back, falcate in the expanded upper half of the flower; filaments, purplish, a little shorter than the segments; ovary, stalked, with a discoid expansion at the base. Cape of Good Hope.

41. S. exigua (Baker).—Leaves, fleshy-herbaceous, ascending, lance-shaped, 1½ to 2 inches long, 3 lines broad, streaked and spotted with purple; flower-stem, straight, 2 or 3 inches high; raceme, somewhat dense, containing from twelve to twenty flowers, and, when fully expanded, oblong, about 1 inch long, and 5 or 6 lines in diameter; pedicels, 1½ to 2 lines long, the lowest ones nodding; perianth, roundish bell-shaped, 1½ lines long, with segments of a deep rosy-purple, and green at the bottom outside; filaments, thread-like, distinctly shorter than the segments; ovary, shortly stalked, with a discoid expansion at the base. Natal.

42. S. Barberi (Baker).—Leaves, produced along with the flowers, fleshy-herbaceous, linear, smooth, 2 to 2½ inches long, 1½ lines broad; flower-stem, 2 to 2½ inches high; raceme, loose, containing five or six flowers, and, when fully expanded, oblong, 12 to 15 lines long and 7 or 8 lines in diameter; pedicels, 1½ to 2 lines long, sub-patent, the lower ones nodding; perianth, oblong bell-shaped, 2 lines long, of a deep rosy-purple colour, greenish at the bottom on the outside; ovary, distinctly stalked, with a discoid expansion at the base. Cape of Good Hope, on the banks of the river Tsomo.

43. S. Cooperi (Hook. fil. "Bot. Mag." t. 5, 580).—Bulb, sub-globose, purple, 1 inch in diameter; leaves, four or five in number, sub-erect, fleshy-herbaceous, linear lance-shaped, gradually narrowed towards the pointed apex, 8 to 10 inches long, 6 to 9 lines broad, green, streaked on the back and spotted at the base with purple; flower-stem, firm, flexuose, 5 or 6 inches high; raceme, somewhat dense,

containing from thirty to fifty flowers, and, when fully expanded, cylindrical in shape, 2 or 3 inches long and 1 inch broad; pedicels, sub-patent, 4 to 6 lines long, the lower ones nodding; perianth, globose bell-shaped, 1½ lines long, with segments half-a-line broad, green on the back, and falcate in the expanded upper half of the flower; filaments, thread-like, 1 line long, of a deep purple colour; ovary, stalked, with a discoid expansion at the base; style, purple, 1 line long, finally projecting slightly. Cape of Good Hope. Grown in Kew Gardens in 1863.

44. S. Zambesiaca (Baker).—Bulb, ovoid, 8 or 9 lines in diameter, the outer coats membranous, lengthened; leaves, two or three in number, produced along with the flowers, fleshy-herbaceous, tender, acute, ovate-lance-shaped, 2 to 2½ inches long, 9 or 10 lines broad, very much undulated at the edges, and narrowed at the base into a foot-stalk an inch long, embracing the stem; flower-stems, erect, very slender, 2 or 3 inches high; racemes, somewhat loose, containing from thirty to forty flowers, and, when fully expanded, cylindrical in shape, 2 or 3 inches long, and 5 or 6 lines in diameter; pedicels, patent, 1½ to 2 lines long; flowers, nodding; perianth, roundish, bell-shaped, 1 line long, greenish on both sides, with segments one-third of a line broad, paler at the edges, and reflexed in the expanded upper half of the flower; filaments, whitish, a little shorter than the segments; ovary, stalked, with no discoid expansion at the base. South-eastern tropical Africa, at Tette, on the banks of the Zambesi River.

45. S. Cameroonia (Baker).—Bulb, ovoid, 8 or 9 lines in diameter; leaves, fleshy-herbaceous, produced along with the flowers, sub-erect, thong-like, 5 or 6 inches long, 6 to 8 lines broad, bluntish and very shortly cuspidate at the apex, and gradually narrowed at the base into a foot-stalk, which embraces the stem; flower-stems, slender, flexuose, 4 to 6 inches high; racemes, loose, containing from twenty to thirty flowers each, and, when fully expanded, of a cylindrical lance-shape, 2 or 3 inches long, and 6 to 9 lines broad; pedicels, sub-patent, 3 or 4 lines long, the lower ones nodding at the apex; bracts, small, sometimes in pairs; perianth, roundish-bell-shaped, greenish, with segments ½ line broad, falcate in the upper part of the flower; filaments, 1 line long, of a deep purple colour; ovary, stalked, with a discoid expansion of the base. Cape of Good Hope and Caffraria. Grown in Kew Gardens in 1862-3.

46. S. prasina (Baker).—Bulb, elongated-ovoid, 9 to 12 lines in diameter; leaves, five or six in number, fleshy-herbaceous, spreading, oblong-lanceolate, 4 to 5 inches long, 12 to 15 lines broad in the middle, acute, lower third narrow, often spotted with purple; stem, flexuose, deflexed, 3 to 4 inches long; racemes, sub-dense, with thirty to fifty flowers, expanding, lanceolate, or sub-cylindrical, 1½ to 2 inches long, 6 to 10 lines broad; pedicels, central, horizontal, spreading, 1½ to 2½ lines long, deflexed inferiorly; perianth, rounded, bell-shaped, greenish; segment ½ line broad, falcate above; filaments, 1 line long, stained with purple; ovary, stipitate, producing discoids at the base. Cape of Good Hope. Grown in Kew Gardens in 1862-3.

47. S. Ludwigii (Baker).—Bulb, ovoid, 8 or 9 lines in diameter; outer coats membranous and lengthened at the apex; leaves, five or six in number, ascending, fleshy-herbaceous, lance-shaped, 2 or 3 inches long, 5 or 6 lines broad, hardly narrowed at the base, gradually narrowed towards the acute apex; flower-stem, 1 to 3 inches high; racemes, dense, containing from twenty to forty flowers each, and, when fully expanded, of a cylindrical lance-shape, 1½ to 2 inches long, and 4 or 5 lines broad; pedicels, 1½ to 2 lines long, the lower ones nodding; perianth, green, roundish-bell-shaped, 1 line long; filaments, purplish thread-like, a little shorter than the segments; ovary, stalked, discoid at the base. Cape of Good Hope.

48. S. moesta (Baker).—Bulb, ovoid, 15 to 18 lines in diameter; leaves, five or six in number, produced along with the flowers, fleshy-herbaceous, lance-shaped, sub-erect, 5 or 6 inches long, 6 to 9 lines broad, spotted with purple, slightly narrowed at the base and gradually narrowed in the upper half towards the acuminate apex; flower-stems, two or three in number, flexuose, 3 or 4 inches long; raceme, somewhat dense, containing from thirty to fifty flowers, and, when fully expanded, of a cylindrical shape, 1½ to 2 inches long, and 6 or 7 lines in diameter; pedicels, ascending, 3 or 4 lines long; perianth, green, oblong-cylindrical, 1½ lines long; filaments, greenish, ¾ line long, distinctly shorter than the segments; ovary, stalked, with a discoid expansion at the base. South-eastern tropical Africa, near Luabo, at the delta of the Zambesi River.

49. S. undulata (Baker).—Bulb, globose, 1½ to 2 inches in diameter, scaly on the lower half, where it meets the soil; leaves, produced after the flower-stem, five or six in number, firmish, lance-shaped, acute, glaucous, smooth, ascending, undulated, 4 or 5 inches long, 3 or 4 lines broad; flower-stem, firm, tapering, 1½ to 2 inches high; raceme, somewhat dense, containing from twenty to thirty

flowers, and, when fully expanded, oblong in shape, $1\frac{1}{2}$ to 2 inches long, and 12 to 15 lines in diameter; pedicels, horizontal, 3 to 5 lines long; perianth, 3 or 4 lines long, oblong bell-shaped, greenish, slightly tinged with purple; filaments, whitish, a little shorter than the segments; ovary, stalked. Cape of Good Hope.

50. *S. Currori* (Baker).—Leaves, produced along with the flowers, fleshy-herbaceous, rounded, cuspidate, 8 or 9 lines long, 7 or 8 lines broad, rounded or slightly heart-shaped at the base, with a distinct foot-stalk, 5 or 6 lines long, which embraces the flower-stem; flower-stem, erect, straight, about 1 inch high; raceme, somewhat dense, containing ten or twelve flowers, and 9 or 10 lines in diameter; pedicels, straight, erect-patent, 5 or 6 lines long; perianth, tubular bell-shaped, $2\frac{1}{2}$ lines long, with strap-shaped purple segments, paler at the edges, and $\frac{1}{2}$ line broad; filaments, pale, thread-like, half the length of the segments; ovary, sessile, top-shaped, with no discoid expansion of the base; style, thread-like, purple, as long as the ovary. Equinoctial parts of Guinea.

51. *S. Richardiana* (Bachling).—Bulb, ovoid, 8 or 9 lines in diameter, and growing under the surface of the soil; leaves, two in number, opposite, fleshy-herbaceous, produced along with the flowers, oblong lance-shaped, smooth, sub-acute, sometimes bearing bulbils at the edges, 2 to $2\frac{1}{2}$ inches long, 8 to 12 lines broad, narrowed at the base into a foot-stalk an inch long, which embraces the stem; flower-stems, one or two in number, erect, 4 to 6 inches high; racemes, somewhat loose, containing from ten to thirty flowers each, and, when fully expanded, oblong or cylindrical in shape, 1 to 3 inches long, and 9 to 12 lines in diameter; pedicels, 3 or 4 lines long, at first nodding; perianth, oblong bell-shaped, 2 to $2\frac{1}{2}$ inches long, greenish, slightly tinged with purple, and with the segments falcate in the upper half of the flower; filaments, purple, a little shorter than the segments; ovary, globose, sub-sessile, with no discoid expansion of the base. Abyssinia.

52. *S. maculata* (Baker).—Bulb, ovoid, 8 or 9 lines in diameter, coated towards the apex, and growing under the surface of the soil; leaves, three or four in number, produced along with the flowers, fleshy-herbaceous, oblong, obtuse, 2 or 3 inches long, 9 to 12 lines broad, spotted on the upper surface, never bearing bulbils at the edges, gradually narrowed at the base into a foot-stalk, which embraces the stem; flower-stems, one or two in number, 4 to 8 inches high; racemes, somewhat dense, containing from twenty to fifty flowers each, and, when fully expanded, 2 to 4 inches long, and 10 to 12 lines in diameter; perianth, 2 lines long, of a greenish-purple colour; filaments, of a deep purple, a little shorter than the segments; ovary, distinctly stalked, with no discoid expansion of the base. The East Indies, everywhere in both the Concavo districts.

53. *S. indica* (Baker).—Bulb, ovoid, $1\frac{1}{2}$ to 2 inches in diameter, scaly at the top; leaves, five or six in number, produced along with the flowers, fleshy-herbaceous, oblong, or lance-shaped, acute, 3 to 6 inches long, 9 to 12 lines broad, often bearing bulbils at the edges, gradually narrowed at the base and embracing the bottom of the flower-stem; flower-stems, one to three in number, flexuose, 2 to 6 inches high; racemes, dense, containing from thirty to sixty flowers each, and, when fully expanded, of an oblong-cylindrical shape, 2 to 4 inches long, 9 to 12 lines in diameter; pedicels sub-patent, 3 or 4 lines long; perianth, $1\frac{1}{2}$ to 2 lines long, somewhat roundish, bell-shaped, of a greenish-purple colour, with segments falcate in the upper half of the flower; filaments, purple, a little shorter than the segments; ovary, globose, distinctly stalked, with no discoid expansion of the base. The East Indian Peninsula and Ceylon. Also recorded from Abyssinia by Dr. Schweinfurth, under the name of *Drimia lilacina*.

54. *S. lilacina* (Baker).—Bulb, ovoid, $1\frac{1}{2}$ to 2 inches in diameter, scaly at the top; leaves, six to eight in number, produced along with the flowers, fleshy-herbaceous, sub-erect, oblong-lance-shaped, acute, undulated, 3 or 4 inches long, 12 to 15 lines broad, narrowed like a wedge at the base into a foot-stalk 1 or 2 inches long, and embracing the stem; flower-stems, one to three in number, flexuose, slender, 4 to 6 inches high; racemes, somewhat loose, containing from thirty to sixty flowers each, and, when fully expanded, cylindrical in shape, 3 to 5 inches long, and 12 to 15 lines in diameter; lower pedicels, sub-patent, 3 to 5 lines long; flowers nodding; perianth, 3 to $3\frac{1}{2}$ lines long, tubular bell-shaped, of a lilac-purple colour, with strap-shaped segments inflated at the side and apex, like those of a *Drimia*; filaments, deeply coloured, 2 to $2\frac{1}{2}$ lines long; ovary, top-shaped, sessile, with no discoid expansion of the base. Nubia.

55. *S. paucifolia* (Baker).—Bulbs, gregarious, ovoid, 12 to 15 lines in diameter, with the top over-ground and scaly; leaves, two in number (rarely three), opposite, produced along with the flowers, patent, fleshy-herbaceous, oblong-lance-shaped, acute, undulated, $2\frac{1}{2}$ to 3 inches long, 9 or 10 lines broad, pale green on the upper surface, marked with darker spots, slightly narrowed at the base, and embracing the stem; flower-stem, firm, not spotted, terete,

3 or 4 inches high; raceme, loose, containing from twenty to thirty flowers, and, when fully expanded, oblong in shape, 3 or 4 inches long, and 15 to 18 lines in diameter; pedicels, 5 or 6 lines long, the lower ones nodding; perianth, greenish, roundish bell-shaped, $2\frac{1}{2}$ to 3 lines long, with segments falcate in the upper half of the flower; filaments of a deep purple colour, a little shorter than the segments; ovary, stalked, with a discoid expansion of the base. Cape of Good Hope. Grown in Mr. Wilson Saunders's garden.

56. *S. socialis* (Baker).—Bulbs, gregarious, ovoid, 15 to 18 lines in diameter, with the top over-ground and scaly; leaves, three or four in number, produced along with the flowers, fleshy-herbaceous, patent, oblong-lance-shaped, acute, 2 to $2\frac{1}{2}$ inches long, 9 to 12 lines broad below the middle, slightly narrowed at the base, of a pale glaucous green on the upper surface, marked with darker spots; flower-stem, firm, terete, not spotted, 2 or 3 inches high; raceme, dense, containing from twenty to thirty flowers, and, when fully expanded, oblong in shape, $1\frac{1}{2}$ to 2 inches long, and 1 inch in diameter; pedicels, $1\frac{1}{2}$ to 2 lines long, the lower ones nodding; perianth, greenish, roundish bell-shaped, 2 to $2\frac{1}{2}$ lines long, with segments falcate in the upper part of the flower; filaments, $1\frac{1}{2}$ lines long, of a deep purple colour; ovary, stalked, with a discoid expansion of the base. Cape of Good Hope. Grown in Mr. Wilson Saunders's garden.

57. *S. lanceæfolia* (Baker).—Bulb, ovoid, $1\frac{1}{2}$ to 2 inches in diameter, with the top over-ground and scaly; leaves, six to eight in number, produced along with the flowers, fleshy-herbaceous, sub-patent, oblong, acute, 4 to 6 inches long, $1\frac{1}{2}$ to 2 inches broad above the middle, narrowed for a short distance at the base, pale green on the upper surface, marked with darker spots; flower-stems one to three in number, firm, terete, 2 to 4 inches long, often curved downwards; racemes, dense, containing from thirty to fifty flowers each, and when fully expanded, oblong in shape, 2 or 3 inches long, and 15 to 18 lines in diameter; pedicels, 5 or 6 lines long, the lower ones bent downwards; perianth, somewhat globose, bell-shaped, $2\frac{1}{2}$ to 3 lines long, with strap-shaped lanceolate segments, which are purple on the inside and greenish on the back; filaments, 2 lines long, of a deep purple colour; ovary, stalked, with a discoid expansion of the base.—Cape of Good Hope, Caffraria, and Natal. *Scilla maculata* of Schrank, Pl. var. Hort. Monac. t. 100, is a variety with flower-stems 6 inches high, and with leaves double the length. A variety, *S. l. ovatifolia* (Baker), has shorter and broadly ovate leaves, 2 or 3 inches long, and 18 to 24 lines broad above the middle. Cape of Good Hope. Grown in Mr. W. Saunders's garden.

58. *S. concolor* (Baker).—Bulb, ovoid, $1\frac{1}{2}$ to 2 inches in diameter, of an ash colour and scaly in the upper part; leaves, 5 or 6 in number, produced along with the flowers, fleshy-herbaceous, falcate, strap-shaped lanceolate, 5 to 8 inches long, 15 to 18 lines broad in the middle, obtuse, or sub-acute, narrowed for a short distance at the base, of a deep green and unspotted on both sides; flower-stems, one to three in number, flexuose, green, 3 or 4 inches high; racemes, dense, containing from thirty to fifty flowers each, and, when fully expanded, oblong-cylindrical in shape, 3 or 4 inches long, and 9 to 12 lines in diameter; pedicels, 2 to 4 lines long, the lower ones nodding; perianth, greenish, roundish bell-shaped, $2\frac{1}{2}$ lines long; filaments, greenish, a little shorter than the segments; ovary, stalked, with a discoid expansion of the base. Cape of Good Hope. Grown at Kew and in Mr. W. Saunders's garden.

59. *S. linearifolia* (Baker).—Bulb, ovoid, $1\frac{1}{2}$ to 2 inches in diameter, growing with the top under the surface of the soil; leaves, four to six in number, fleshy-herbaceous, somewhat erect, linear, 9 to 12 inches long, 4 to 8 lines broad, acute, narrowed for a short distance at the base, of a pale green, and spotted with purple for a short distance down the back; flower-stem, flexuose, 3 or 4 inches high; raceme, somewhat dense, containing from thirty to forty flowers, and, when fully expanded, oblong in shape, 2 or 3 inches long, and 15 to 18 lines broad; pedicels, 3 to 5 lines long, the lower ones nodding; perianth, $2\frac{1}{2}$ to 3 lines long, oblong bell-shaped, of a deep purple on the inside, greenish on the outside, with segments falcate in the upper half of the expanded flower; filaments, $1\frac{1}{2}$ to 2 lines long, deeply coloured; ovary, stalked, with a discoid expansion of the base. Cape of Good Hope and the Transvaal district. Grown in Mr. W. Saunders's garden.—*Drimia angustifolia* of Kunth is, from the description, probably, a form of this species with narrower leaves. They are said to be $1\frac{1}{2}$ lines broad.

60. *S. concinna* (Baker).—Bulb, ovoid, growing under the surface of the soil; leaves, three to four in number, produced along with the flowers, fleshy-herbaceous, somewhat erect, linear, 8 or 9 lines broad, narrowed for a short distance at apex and base, of a deep glaucous green colour, marked on the back with purple spots; flower-stem firm, erect, terete, 2 to 6 inches high; raceme, dense, containing from twenty to thirty flowers, and, when fully expanded, oblong in shape, $1\frac{1}{2}$ to 2 inches long, and 12 to 15 lines broad; all

the pedicels erect-patent, the lowest ones 4 or 5 lines long; perianth, oblong bell-shaped, 2½ lines long, of a deep rosy-purple on the inside; filaments, 1½ lines long, deeply coloured; ovary, stalked, with a discoid expansion of the base. Cape of Good Hope. Grown in Mr. W. Saunders's garden.

61. *S. subglauca* (Baker).—Bulb, sub-globose, 1½ to 2 inches in diameter, growing under the surface of the soil; leaves, five or six in number, produced along with the flowers, fleshy-herbaceous, strap-shaped, lanceolate, 9 or 10 inches long, 1 inch broad in the middle, acute, distinctly narrowed at the base, pale glaucous green on the upper surface, slightly spotted with purple on the back; flower-stem, spotted, 3 or 4 inches high; racemes, somewhat loose, containing from thirty to forty flowers each, and, when fully expanded, 3 or 4 inches long and 18 to 20 lines in diameter; pedicels, 6 or 7 lines long, the lower ones nodding; perianth, oblong bell-shaped, 3 lines long, greenish outside, purple within; filaments, 2 lines long, of a deep purple colour; ovary, stalked, and with a discoid expansion of the base. Cape of Good Hope. Grown in Mr. W. Saunders's garden.

62. *S. lorata* (Baker).—Bulb, ovoid, 1½ to 2 inches in diameter, growing under the surface of the soil; leaves, five or six in number, produced along with the flowers, fleshy-herbaceous, somewhat erect, thong-like, lance-shaped, 8 or 9 inches long, 10 to 12 lines broad in the middle, acute, narrowed for a short distance at the base, of a deep green colour, spotted with purple downwards on the back; flower-stem, terete, erect, 8 or 9 inches high, spotted on the lower half; raceme, somewhat dense, containing from thirty to sixty flowers, and, when fully expanded, of an oblong-cylindrical shape, 3 or 4 inches long, and from 18 to 21 lines broad; pedicels, 4 or 5 lines long, the lower ones nodding; perianth, of a livid purple colour, the segments tinged with a greenish hue on the back and edges, 3 or 4 lines long, and oblong bell-shaped; filaments, purple, shorter than the segments; ovary, stalked, and with a discoid expansion of the base. Cape of Good Hope. Grown in Mr. W. Saunders's garden.

63. *S. zebrina* (Baker).—Bulb, 1½ to 2 inches in diameter, growing almost beneath the surface of the soil; leaves, five or six in number, produced along with the flowers, fleshy-herbaceous, strap-shaped lanceolate, somewhat erect, 8 to 12 inches long, 12 to 21 lines broad, acute, slightly narrowed at the base, of a pale glaucous green on the upper surface, streaked with purple on the back, and spotted with purple downwards; racemes, dense, containing from thirty to forty flowers each, and, when fully expanded, of an oblong cylindrical shape, 3 or 4 inches long and 15 or 16 lines in diameter; pedicels, 3 or 4 lines long, the lower ones nodding; perianth, roundish bell-shaped, 3 lines long, of a greenish-purple colour; filaments, of a deep purple, distinctly shorter than the segments; ovary, stalked, and with a discoid expansion of the base. Cape of Good Hope. Grown in Mr. W. Saunders's garden.

64. *S. spatulata* (Baker).—Bulb, ovoid, 2 to 2½ inches in diameter, purple, the upper part over-ground and scaly, leaves, five or six in number, produced along with the flowers, fleshy-herbaceous, thong-like, spoon-shaped, 6 to 8 inches long, 18 to 21 lines broad, of a pale glaucous green colour, marked with darker and purple spots; flower-stems, flexuose, 3 or 4 inches high; racemes, dense, containing from thirty to forty flowers, and, when fully expanded, 3 or 4 inches long and 18 to 21 lines in diameter; pedicels, 6 or 7 lines long, the lower ones nodding; perianth, oblong bell-shaped, 3½ lines long, purple on the inside, greenish on the outside; filaments, of a deep purple colour, a little shorter than the segments; ovary, stalked, and with a discoid expansion of the base. Cape of Good Hope. Grown in Mr. W. Saunders's garden.

65. *S. Kirkii* (Baker).—Leaves, produced along with the flowers, fleshy-herbaceous, thicker and firmer than those of any other species, oblong lance-shaped, acute, 6 to 8 inches long in the blade, 1½ to 2 inches broad, narrowed at the base into a wedge-like, broad, channelled foot-stalk, 2 to 4 inches long; flower-stem, stout, about a foot high; raceme, loose, containing from thirty to forty flowers, and, when fully expanded, 5 or 6 inches long, and 18 to 20 lines in diameter; pedicels, 2 to 5 lines long, the central ones sub-patent, lower flowers nodding; perianth, 1½ lines long, tubular bell-shaped, greenish outside, purple within, with narrow segments which are rolled inwards at the sides and apex, like those of a *Drimia*; filaments, 3½ lines long, of a deep purple colour; ovary, stalked. Zanzibar.

66. *S. lanceolata* (Baker).—Bulb, sub-globose, 15 to 18 lines in diameter, and growing entirely under the surface of the soil; leaves, five or six in number, produced along with the flowers, fleshy-herbaceous, lance-shaped, acute, 3 or 4 inches long, 8 to 10 lines broad, green, without spots; flower-stem, flexuose, 4 or 5 inches high; raceme, very loose, containing from eight to twelve flowers, and, when fully expanded, 1½ to 2 inches long, and 1½ inches broad; pedicels, dotted with red, sub-patent, the lower ones 5 or 6 lines long; perianth, tubular bell-shaped, 4 to 4½ lines long, of a purplish-

green colour; filaments, deeply coloured, a little shorter than the segments; ovary, stalked. Cape of Good Hope.

67. *S. floribunda* (Baker).—Bulb, sub-globose, 2 to 2½ inches in diameter, growing almost entirely under the surface of the soil; leaves, five or six in number, produced along with the flowers, fleshy-herbaceous, somewhat erect, thong-like, about a foot long, 21 to 24 lines broad in the middle, acute, hardly narrowed at the base, of a pale green colour, marked with deeper spots; flower-stem, stout, erect, 6 to 9 inches high; raceme, somewhat dense, containing from sixty to 100 flowers or more, with a thickened, furrowed axis, and when fully expanded, 6 to 8 inches long and 2 inches broad; pedicels, 6 to 8 lines long, the central ones patent, lower ones nodding; perianth, oblong bell-shaped, 4½ to 5 lines long, greenish on the outside, and rosy-purple within; filaments, 3 lines long, deeply coloured; ovary, stalked, and with a discoid expansion of the base. Cape of Good Hope. Grown in Mr. W. Saunders's garden.

68. *S. pendula* (Baker).—Leaves, produced along with the flowers, fleshy-herbaceous, thong-like, 12 to 15 inches long, 15 to 16 lines broad in the middle, acute, slightly narrowed at the base, flattish, of a pale green colour, very faintly spotted; flower-stem, very slender, flexuose, 8 or 9 inches high; racemes, somewhat dense, containing from thirty to sixty flowers each, and, when fully expanded, 3 to 6 inches long, and 2½ to 3 inches in diameter; pedicels, very slender, 9 to 15 lines long, many of them nodding; perianth, 4 to 4½ lines long, oblong bell-shaped, greenish on the outside, purple within; filaments, of a deep purple colour, a little shorter than the segments; ovary, stalked, and with a discoid expansion of the base. Cape of Good Hope.

69. *S. princeps* (Baker).—Bulb, globose, 2½ to 3 inches in diameter, growing entirely under the surface of the soil; leaves, five or six in number, produced along with the flowers, fleshy-herbaceous, thong-like, 18 to 24 inches long, 2 to 2½ inches broad, acute, narrowed at the base, of a pale green colour, marked with deeper spots; flower-stems, two or three in number, stout, 7 to 9 inches high; raceme, dense, containing from 150 to 200 flowers, with a thickened furrowed axis, and, when fully expanded, a foot long, and from 3 to 3½ inches in diameter; pedicels, 12 to 15 lines long, the central ones patent, the lower ones nodding; perianth, oblong bell-shaped, 4½ to 5 lines long, reddish-purple on the inside, and greenish without, with segments 1 line broad, reflexed in the upper half; filaments, 3 to 3½ lines long, of a deep purple colour; ovary, stalked, and with a discoid expansion of the base. Cape of Good Hope. Grown at Kew and in Mr. W. Saunders's garden.

Doubtful Species of this Sub-genus.

70. *S. viridiflora* (Baker) (*Drimia viridiflora*, Ecklon, Kunze, *Linnæa*, xx. 10).—Leaves, linear awl-shaped, channelled, shorter than the flower-stem; raceme, many-flowered; pedicels, patent, shorter than the flowers; perianth, greenish on the outside, whitish within. Cape of Good Hope (Gueinzins). I have not seen a specimen.

Sub-genus III.—*Endymion* (Baker).

Perianth, normally blue, but frequently varying to rosy-purple or whitish; segments, remaining united for a considerable time in the lower half of the expanded flower; filaments, in two distinct series, inserted above the base of the segments; ovary, sessile, with numerous ovules in each cell; bracts, linear, in pairs.

71. *S. hispanica* (Mill. Diet.).—Bulb, ovoid, 6 to 12 lines in diameter; leaves, five or six in number, produced along with the flowers, fleshy-herbaceous, smooth, ascending, linear thong-like, 6 to 9 (or, in cultivated specimens, 12) lines broad, bluish, convex on the back; flower-stem, 6 to 9 inches high; raceme, equilateral, somewhat loose, containing from six to twelve flowers; bracts, linear, in pairs, 6 to 9 lines long; lower pedicels, 6 to 12 lines long; flowers, more spreading than those of *S. non-scripta*; perianth, sub-globose, bell-shaped, 6 to 9 lines long, with segments 2 to 2½ lines broad; filaments inserted alternately above the base, and at the top of the upper third of the segments; free part, 2½ to 3 lines long; ovules, six to eight in each cell; capsule, like that of *S. non-scripta*. Spain and Portugal. Frequently grown in gardens. *S. campnallata* ("Bot. Mag." t. 1102) is a form with spreading flowers, a little smaller and more oblong bell-shaped, approaching *S. non-scripta*. It is also found in Southern France and in Italy.

72. *S. non-scripta* (Hoffm. et Link.; *Hyacinthus non-scriptus*, Linn.; *Scilla nutans*, Smith).—Bulb, ovoid, 6 to 9 lines in diameter; leaves, five or six in number, produced along with the flowers, fleshy-herbaceous, smooth, ascending, linear-thong-like, convex on the back, 8 to 12 inches long, 3 to 6 lines broad; flower-stem, 6 to 12 inches high; raceme, nodding, containing from six to twelve flowers, somewhat turned to one side of the stem; pedicels, 4 to 6 lines long, nodding when in flower, but ascending when bearing fruit; bracts, linear, in pairs, 6 to 9 lines long; perianth, tubular, bell-shaped, 6 to 9 lines

long, with strap-shaped segments, $1\frac{1}{2}$ to 2 lines broad; filaments, alternately inserted in the middle of the segments (when the free part is $1\frac{1}{2}$ lines long), and alternately at the top of the lower fourth (when the free part is a little longer); ovules, six to ten in each cell; capsule, sub-sessile, ovoid, 5 or 6 lines long; seeds, globose, black, scarcely 1 line in diameter.—Britain, and extending to Spain, Italy, and Illyria. *S. cernua* (Hoff. et Link.; *Ilyacanthus cernuus*, Linn.), is a small Spanish and Portuguese form, with reddish flowers. There is a garden form called *bracteata*, distinguished by its elongated bracts, which are 2 inches or more in length.

GARDENING FOR THE WEEK, AND AMATEUR'S CALENDAR.

The Flower Garden and Pleasure Grounds.

CONTINUE to increase, by cuttings, the stock of bedding *Pelargoniums* for next year's embellishment as fast as such cuttings can be obtained, although it will still be unadvisable to, in any degree, despoil the flower beds for this purpose; but, in the meantime, endeavour to make the most of any surplus stock which may have been left in pots at the time of bedding out, or which may have been planted in the reserve ground. Attend well to the watering, stopping, and pegging down, when required, of plants forming what are known as "carpet beds," as such beds will be found to be by no means the least attractive in the flower garden during the present season, being composed, in a great measure, of succulents and other plants upon which extreme drought has not so injurious effects as it has upon many other decorative plants. The brilliantly coloured foliage of the *Alternantheras*, *Colasces*, *Golden-feather Pyrethrum*, &c., renders the use of flowering plants little, if at all, necessary in this style of planting. Still, a bright blue colour is a desideratum which is hardly secured in the glaucous hue of the foliage of the *Echeveria secunda glauca* or the *Sedum glaucum*; but can, nevertheless, be obtained by using some of the dwarf blue *Lobelias* of the "pumila section," and of which the new double variety is decidedly the best, and appears to be less apt to die off in patches than some of its single flowering congeners. Beds of sub-tropical plants should still be abundantly supplied with water, as they are nearly all gross feeders; and tall-growing species, such as the *Castor-oil* plants, should, if in exposed situations, be securely staked to prevent injury from high winds. Very few annuals can be confidently recommended as bedding plants, on account of their short duration; although such species as the blue *Lobelias*, the *Perilla*, and the *Golden-feather Pyrethrum*, generally succeed best when raised from seed every season. It is also found that the *Abronia umbellata grandiflora* succeeds well when treated in this manner, and forms an exceedingly pretty and interesting bed, more particularly during such dry and hot seasons as the present has so far been, and as its native habitat is the loose dry sands on the sea coast of tropical countries, it will naturally suffer little, if at all, from the heat and drought of this country. Its habit of growth is that of a trailing plant, which, with a very little training or regulating, soon completely covers the surface of the soil, while its stout glossy dark green foliage is plentifully bespangled with sparkling trusses of bright pink white-eyed flowers, which do not rise above 6 inches from the surface of the soil. Plant out in properly prepared soil, in beds or patches, where they are intended to flower, rooted cuttings of *Pinks* and *Picotees*, also of *Pansies* and double-flowered *Wallflowers*, &c., and as it is advisable to perpetuate unusually fine varieties of *Sweet Williams* by cuttings, if these cuttings were inserted under hand-glasses when the plants were in flower, they will now be rooted, and may at once be planted in beds or borders, where they are intended to remain. Plant out at the same time the various sorts of biennial and perennial hardy plants which have been raised from seed, including the German and other *Wallflowers*, the strain of which has of late years been so greatly improved, that such seed generally produces varieties nearly, if not altogether equal to the old double sorts, which can be perpetuated by cuttings only. Plant also *Brompton* and *Queen Stocks* in situations where they are intended to flower; and where it is desired to have the *Ten-week* and *Intermediate* sorts in flower in spring, they should be sown now, and a portion of them, at least, should be afterwards potted-up and kept in cold pits or frames during winter. Look frequently over beds of seedling *Hollyhocks*, and pull up at once all worthless varieties as soon as they flower, and increase promising seedlings and named sorts by cuttings or eyes. Attend also to the watering of *Auriculas* and *Polyanthuses* in pots, keeping them, as yet, in a somewhat shady situation, and free from weeds, &c.—P. GRIEVE, *Culford, Bury St. Edmunds*.

Roses.

Where pot *Roses* are required for forcing, if not already done, no time should be lost in giving them a shift, and in seeing that the drainage is effective. *Roses*, to keep up a supply of bloom from December to March, should not, however, be shifted; only see to the drainage, and top-dress with some nice fresh loam and rotten dung, as it is rather too late now to disturb the roots too much. The drainage of the pots sometimes gets filled up through worms; and, in that case, water continually given sours the soil and rots the roots. When this occurs, I shake the plants out, wash their roots, and while wet, sprinkle them with sand and re-pot. In this way I have saved many a plant of some of the best varieties. The best compost for pot *Roses* is half loam, half good rotten dung, and plenty of sharp sand; silver-sand is too fine. I have used for some time washed road grit, but river-sand, where it can be got, is best for *Roses*, which require to be potted tolerably firm. Pick off all flower buds, and keep down mildew, to which pot *Roses* generally are subject this month. I have found syringing with soap-suds and sulphur a good preventive. It is, however, rather too unsightly to syringe planted-out *Roses* with this mixture, as it stains the foliage. Cuttings may now be made of the ripened shoots. They should be removed at the point from which they grow from the old wood, and a slip of this wood should be removed with them, forming "a heel." The cuttings, about 3 inches long, should be inserted to the depth of 1 inch, round the edge of a pot filled with a light rich soil of leaf-mould and loam, with an abundance of silver-sand; and being well pressed round the roots, and well watered through the rose, should be put in a frame under a north wall until they have "callused." They should then be placed in bottom-heat under glass, and when rooted should be dignified with pots of their own, restored for a little while to heat, and then gradually inured to the air, grown on, and re-potted.—H. G.

Indoor Plant Department.

Although most kinds of indoor plants will now have completed their growth, they should nevertheless still receive abundance of water, be kept as far apart as possible, and have plenty of ventilation. Such as are in flower on front stages will still be benefited by a little shading. Introduce from frames, pits, and greenhouses successions of flowering and fine-leaved plants, and those turned out to accommodate them, if annuals or biennials, and seed sowing is not an object, should be discarded at once; perennials should be retained, and have their flower-spikes cut off, and the plants placed on north borders, or if necessary potted and placed in frames. Greenfly, thrips, mealy bug, and scale must be vigilantly searched for and destroyed. Large plants of *Camellias*, now that their wood is pretty firm and their flower-buds well developed, should be placed out of doors in shady sheltered places, and their pots should be fixed in position by means of three or four stakes driven into the ground. Syringe every fine afternoon, so as to keep them fresh and clean. Such plants as are not placed out of doors should be kept in cool, light, airy houses, their leaves, if dirty, should be washed, and the plants should be kept well watered. Young growing plants, if necessary may be re-potted, and also spring grafted plants. The ligatures may in nearly all cases now be removed from the latter; lateral growths on the stocks rubbed off, and part of the points of the stocks cut off if the scions are making good progress. Proceed with the grafting of *Camellias* as previously directed, and propagate an additional quantity of stocks of *C. japonica* from cuttings. If a portion of a north wall in any cool house can be devoted to this sort, its young shoots may be used every August for propagating for stocks. A close frame or a very gently heated bed is the most suitable place in which to strike them. If last year's cuttings, when rooted, have been potted singly and grown on favourably since, they may now be turned out into a cold pit, so as to get their young wood well ripened. They will then be in a good condition for "working" on next year. Pick decayed blooms off *Heaths*, and encourage the ripening of the wood by fully exposing the plants, either by plunging them out of doors in a bed of ashes, or by keeping them in pits or frames that are well ventilated night and day. No more pinching should be done now, unless it be to remove any useless growths in the centre of large specimens, which growths are generally very weakly and subject to disease. Do not water the plants overhead, but supply them liberally at the root, and pour plenty of water about the floor of the house or on the beds. Any young plants that were pricked off three in a small pot in the spring may now be potted off singly and placed in a cool frame. The earliest *Azaleas* should now have completed their growth and formed well-developed flower-buds; therefore remove them to cooler quarters that are light and well ventilated. Water *Azaleas* plentifully at the roots, but not overhead, and maintain a moist atmosphere by spilling plenty of water about the floor and on the stages. Indeed, towards the end of this

month all the plants, both early and late, should be transferred to cooler houses; but on no account put them out of doors. Pick off withered leaves, and destroy thrips, scale, and any other depredators that may make their appearance. No more pinching of the shoots should be done now; on the contrary, the maturation of the wood should be the main object kept in view. It is a curious fact, however, that young *Azaleas* may be treated for the first twelve or eighteen months after being grafted and re-potted, as cool stove plants, with beneficial effects in the way of securing a strong and rapid growth; and, if properly attended to in the matter of pinching, they will form excellent and stubby plants. Those plants that were grafted about the end of June and first of July, will now have taken well; therefore the ligatures should be cut away, and the plants re-potted from thumb-pots—which are commonly used for stocks that are to be grafted—into 60-sized ones, and still kept moderately close. Proceed with the grafting of these plants, if not already finished, as recommended last month. Re-pot and place in pits some *Zonal Pelargoniums* for late blooming, and pot off rooted cuttings of show varieties. Keep up a succession of *Fuchsias*.

Soft-wooded Plants.

Of *Gomphrena globosa*, have a good stock of plants, both in flower and coming forward; they may be treated like *Balsams*, but less liberally, and should be protected from heavy rains. Preserve some of the best flowered *Balsams* for seedling purposes; keep plants of them for late blooming gradually shifted as they require it, and keep the flower-buds picked off until a short time before they are required to open. *Balsams*, as well as *Cockscombs* and other *Celosias*, should be grown in cool pits, with the sashes removed during the day, and replaced, but tilted up, at night. Sow *Mignonette* in pots; thin out advancing plants, and shift them, if necessary, into larger pots without injuring their roots. Sow the latest batch of hybrid *Calceolarias*, and prick off or pot singly plants from previous sowings. *Cineraria* seedlings or off-sets should be shifted when necessary, using a rich soil for the purpose, and place the plants on a layer of gravel or ashes, in a frame with a north aspect. Pot on Chinese *Primroses*, using a light rich soil, and pinch and grow on moderately *Bouvardias* for winter blooming. Keep hybrid herbaceous and other *Begonias* as near the glass as possible, and shade them a little from bright sunshine. *B. Weltoniensis* is one of the best compact autumn blooming plants which we possess. When *Begonias* become pot-bound give them a little manure-water occasionally. Propagate this class of plants by means of seed and cuttings, but be careful not to cover the cuttings with a bell or hand-light, as they strike better without such assistance. Young *Hydrangeas* for September blooming should be kept moderately close and well watered; but old stocks that were potted in spring and since plunged out of doors, or which, having their roots cut round, are now lifted and placed in large pots, will also yield a great quantity of late blooms. Pot a few plants of the common and larger-growing varieties of *Mask* in rich soil, and grow them against a wall with a north aspect, for blooming between September and Christmas. Keep the different varieties of *Monochætum* in a growing temperature, and pinch them in no longer. Give *Chrysanthemums* plenty of manure-water, and take off and strike a few flowering points for dwarf plants. Tall plants produce the best single blooms, and pyramidal or mushroom trained ones the greatest profusion of flowers. *Nerines* that have done blooming should be kept moderately dry; and *Cyclamens* should be examined and watered a little more liberally than they have been, *Lantanas*, particularly one-year old plants, if kept pinched until now and grown on moderately, will have formed good plants that will continue flowering for a long time. Keep succession plants of *Coleus* in open frames, merely protecting them from wind and rain; in this way they grow freely and sturdily, and seldom require pinching. A few *Coleuses* may be propagated for keeping through the winter, as young well-hardened or half-starved plants keep better than old ones, and in spring under exciting treatment they readily take to growing and yield plenty of cuttings. The same remarks are equally applicable to *Iresines*, *Centaureas*, and *Altemantheras*. *Lilies*, as soon as done flowering, should be placed in a sheltered position out of doors, and watered a little until their stalks have withered, when the pots may be laid on their sides to prevent wet getting to their bulbs. Treat succession plants liberally, as well as those of *Campanula pyramidalis*. Where *Dahlia imperialis* is grown, the plants should have been kept out of doors from June till now, and then introduced into a little heat, when they will soon expand their flowers. *Salvias* form excellent winter-flowering plants, and old plants may be started now for that purpose, and young ones for winter and early spring use. In stoves, as in other plant houses, our chief object should be to get the wood well ripened. Ventilate well in the first part of the day, close early, and shade moderately.

Train out the shoots of *Dipladenias* along the roof. Store away in dry places *Achimenes* and *Gloxinias* that have flowered early, and grow on moderately *Gesneras* of the *Exoniensis* section. Transfer such *Allamandas* as have come well into bloom to the conservatory, where they continue longer in perfection than in warmer quarters. Thin out the shoots of *Bougainvilleas* as soon as the flowers are shed, preserving only such as are necessary for next year's work. Keep *Aphelandra Roezlii* in a growing condition; this is one of the best and most showy of winter-blooming plants. Some of the earliest started *Caladiums* may be permitted to go to rest, as may also early-bloomed plants of *Clerodendron squamatum*. Plants of *Euphorbia Jacquinæflora* and *Poinsettia pulcherrima* should be encouraged to make growth, and should be kept near the glass. The general stock of young plants may be re-potted and kept growing a little throughout the whole year. *Libonia floribunda* and *Sericographis Ghiesbreghtiana* should now be permitted to grow without further pinching; they will form good blooming plants for winter use. Preserve a young stock of *Torenia*s, *Pentas*, *Scutellarias*, *Centradenias*, *Thysacanthus*, &c., as well as of fine-leaved plants for decorating the front stages, baskets, and apartments. Most of the stove plants may now be increased by means of cuttings made of the half-ripe wood, as well as from seeds. Keep *Gardenias* in a vapour-bath, a mode of treatment that applies equally well to the *Eucharis amazonica*, and to *Marantas* and *Alocasias*. Stove aquariums should be kept clean from *Conferve*, as well as from the decaying leaves and flowers of *Nymphaeas*, *Nelumbiums*, and other aquatic. In the case of Ferns, while the weather is fine, fire-heat may almost be dispensed with, provided Ferneries containing tender plants are shut up early. Shading should still be used during strong sunshine, for the young fronds are yet tender, and the sun's rays powerful. Abundance of water must be given at the roots, and a gentle syringing overhead to *Aspleniums*, *Polypodiums*, &c.; but *Adiantums*, *Nothochlenas*, and *Gymnogrammas* prefer having their leaves kept dry. A moist atmosphere must be maintained, especially in the tropical Fernery. Thick shading must be used in the case of filmy Ferns, which, if in cases, may be assisted by green gauze, in addition to the ordinary canvas outside, or a thick coating of paint may be rubbed over the glass outside. They must be kept cool and in a moist atmosphere, and gently dowed overhead daily. Take off and wipe the bell-glasses used for covering them every day, or wipe the glass inside the cases, so as to preserve a sweet and genial atmosphere. Greenhouse Ferns require to be kept cool and in well ventilated houses or pits, and hardy Ferns in pots should be placed in frames having a northern aspect, or they may be set against a wall having a similar position. Seedling Ferns, which may now be picked up on the surface of pots, damp walls, paths, old stages, and amongst *Orchids*, should be selected, potted, or inserted in wire baskets, or they may be left where they are, for yielding fronds for associating with cut flowers during winter and spring.

Orchids.

Less water and shading will now be required in the case of such plants as have finished their season's growth, but *Masdevallias*, *Odontoglossums*, *Oncidium macranthum*, and many *Dendrobes*, which will now be growing freely, must have a copious supply, and as much light and air as possible during fine weather. *Cypripediums* should be syringed once or twice daily, and *Cattleyas*, *Lalias*, and other leathery-leaved species will be all the better for occasional spongings with clean tepid water. The bare surfaces of the pots should be covered afresh with living *Sphagnum Moss*, and plants in baskets should be overhauled and examined every two or three days, while those on blocks will require attention oftener. A little fire heat will be needful for the cool houses on cold nights, but air should still be left on night and day. Plants in flower, such as *Odontoglossos*, *Dendrobes*, *Cattleyas*, *Lalias*, and *Cypripediums*, may be removed to a drier house or to the conservatory, where they will last much longer in perfection than in an atmosphere heavily charged with moisture. Cleanliness should prevail in every department, and all pipes, boilers, and other appliances should now be seen to before sharp weather sets in. Now is a good time for carrying out any repairs not already attended to. Potting may still be done in the case of strong-growing species and imported plants. Now, too, is a good time to re-pot *Disas* that have finished blooming, using a fresh open compost of peat, leaf-mould, and living *Sphagnum*, with sufficient coarse sand or grit to keep the whole open and porous.—F. W. BURRIDGE.

Hardy Fruit.

The gathering and storing of ripe fruit now claims considerable attention. The temptation is strong to gather fruit before it is ripe, as every day the nearer it approaches to perfect maturity, the dangers to which it is exposed increase. Insects lurk in hidden places to devour it, and hosts of hungry birds hover over it, but once safely

stored it is secure. Still, it must not be gathered too soon. The last service the growing tree confers on fruits, is to fill them brimful of flavour, and if we sever the connection prematurely, this service cannot be rendered. The result is, the fruit becomes shrivelled, or preserves a tartness more sharp than agreeable. In no simple operation is the skill of the cultivator more severely tested, than as regards the right time and mode of gathering fruit. Neither too soon nor too late must be our rule. Each fruit has the right day, perhaps, its proper hour, to be gathered—a set time, in which it has reached the greatest perfection. If this be true, and it is, how often in our hap-hazard mode of harvesting, must we, as a matter of course, make mistakes. No doubt, as a rule, fruits are gathered too soon; still, it is possible, though less excusable, to err on the other side. There is hope of a fruit gathered too early. Many ripen more or less after being gathered, but a fruit once past perfection is comparatively ruined. In general terms, it may be stated, that no fruit should be allowed to drop from the tree, certainly no stone fruit. The experienced eye can readily detect the gathering signs of maturity; and just as the fruits are about to fall, the cultivator's hand should be found waiting to receive them. A word as to the time of day to gather fruits; this has often to be determined by convenience. But supposing a choice possible, early in the morning is the best time, when the nourishing dews or quiet coolness, and darkness of the night will have given the last touch of quality to the fruit; gather it before the sun warms or dissipates part of its lusciousness and flavour. The worst time to gather fruit is at noon, when the sun expends its maximum force upon it. No fruit should be gathered—none sent to the table—warm, nor must it be made cool by being iced; a sudden chill as well as a fierce heat, drives the flavour out of it. Flavour is a more fugitive quality in fruits than many seem to think. Hence the importance of these minute instructions. Fruit should be gathered tenderly and touched gently; the true cultivator is ever careful not to mar the beauty or blemish the flesh of his fruits, each bruise being a step towards decomposition. Gather the fruit for the day's consumption as early in the morning as possible, store it in single file in a cool place till wanted; dish it up with a profusion of fresh green leaves, and arrange it with taste and judgment, and in quantity proportioned to the number of guests, and it will be sure to be appreciated and enjoyed. In gathering for storing in the fruit-room use shallow baskets padded with cotton wool, carry and store the fruit in single layers, and it will keep well and go to table in its season perfect alike in form, appearance, and flavour.—D. T. FISH.

Kitchen Garden.

Potatoes in many places, in consequence of the retarding influence of spring frosts and the subsequent check caused by drought, are small, and the crop therefore light. Super-tuberculation also is taking place amongst later crops to a considerable extent; and, in all cases where the skins of the tubers are sufficiently set, it would be advisable to take up the crop, but not to store it in large heaps at present. Although the main crops of Broccoli and winter Greens should have been planted last month, there is yet time to make a further planting for spring use, provided good plants can be obtained. They will not attain the same development as those planted earlier, but, wherever the Potato crop falls short, all vacant spots should be filled up, as the chances are, they will be found to be useful in spring. Make the last sowing of White Lisbon and Tripoli Onions; sow thickly, as they may be transplanted in spring; in fact, in all places where the Onion maggot is troublesome, this may be looked upon as the most reliable time to sow, so as to escape its ravages. This is also a good time to sow prickly Spinach for spring use. It delights in deep, rich, well-manured land; both this and previous sowings should be thinned out to about 1 or 5 inches apart, and, if necessary, the thinnings may be planted to furnish a succession. Wherever no provision has been made for a good supply of Parsley for use in bad weather, such should now be seen to; plants from the main bed may be lifted, the larger leaves cut off, and the roots planted in some warm sheltered place, where they can easily be protected by placing a frame over them. Hurdles thatched with straw form some of the most useful protections for this and other crops, and are usually available almost everywhere. A row of Parsley might also be planted at the foot of a south wall for the sake of early growth in spring. Late Peas now coming into bearing, considering the ordeal through which they have passed, are looking well, and are at present free from mildew. It is necessary that great care should be exercised in gathering the crops so as not to break any of the shoots or foliage. This has more significance now than early in the season, as upon its observance depends, in some measure, their continuous bearing. South borders will again prove useful for the purpose of sowing and transplanting such things as Endive, Lettuces, Radishes, &c. We have latterly had cooler weather, accompanied by moderate, but refreshing, rains, which have very much benefited everything, and the growth of recently planted crops will now be very

much accelerated. Keep the surface stirred among growing crops; never allow a weed to seed; and thus weeds will soon cease to be troublesome. Clear off all run-away crops the moment they are done with; the proper place for such matters is the pigstye, where what is not consumed will be quickly converted into excellent manure. Any bad smell arising from the process of fermentation will be neutralised by a free use of the long littery manure from the stables. In the same way any bad smells arising from the fermentation of short Grass, or other vegetable refuse, in the rubbish yard should be attended to with sprinklings of lime; burnt earth or dry earth of any kind is a capital deodoriser. If any symptoms of mildew should appear upon Cucumbers in frames, or on ridges in the open air, sprinkle sulphur freely amongst them.—E. HOBDAV.

How to Soften Hard Putty.—Amateurs who, for amusement, make themselves "handy" about their premises, sometimes adopt modes of doing work that would be repudiated by professed workmen, either because it was not the custom of the trade or that the work was dispatched too quickly. My object is to assist those who may sometimes try their hands at glazing. Those who have repaired broken glass in an old greenhouse or pit know well the labour of cutting out the hard putty without destroying the wood-work. After many trials, and with a variety of differently shaped tools with various success, I at last accomplished my end by the simple application of heat. My first experiment was with a soldering iron, when, to my great delight, I found the putty become so soft that the broken glass could be removed by the fingers and the putty be easily scraped away. All that is required is a block of iron about 2½ inches long by 1½ inches square, flat at the bottom, and drawn out for a handle, with a wooden end like a soldering-iron. When hot (not red) place this iron against the putty or flat on the broken glass, if any, and pass it slowly round the sides of the square. The heat will so soften the putty that it will come away from the wood without difficulty. Some of it may be so hard as to require a second application of the hot iron, but one experiment will give sufficient instruction to meet all difficulties.—C. J. C., *Canford Bridge*.

The Gardeners' Royal Benevolent Institution.—In reference to a "Head Gardener's" observations upon this institution (see p. 102), I should like to make one or two remarks. In the first place, the smallness of the pensions given deters gardeners from becoming subscribers, owing to the fact that they are not sufficient to exist upon now-a-days, whatever the original pensioners may have managed to do. Raise the pensions even at the cost of electing fewer pensioners at each half-yearly election, and as death makes vacancies, there will be fewer to pay until the requisite funds come in to give an increased sum per annum. By this means a greater inducement would be offered to gardeners to join the charity. I often peruse the reports of various benevolent societies, and I must confess that the gardeners' pensions are the lowest of any. Let each member put the question to himself—Is the miserable sum offered to live upon when old age comes, any enticement for the craft to give their guinea per annum? Let the committee make it to a gardener's interest to subscribe, and they will soon have an increase of members. The majority of gardeners have but few friends left to give them a helping hand after they have reached sixty years of age, and I certainly do hope that some scheme may be introduced, by which the pensions may be increased. There are, doubtless, many large-hearted subscribers, who, if they knew that there was an endeavour being made to give poor gardeners a trifle more, would only be too happy, in some cases, to double their subscriptions, and in others, to give some three or four shillings more per annum. In the latter case subscribers would not miss the trifling sum, and they would have the satisfaction of knowing what an inestimable benefit it was to the recipients.—C. D., *Chelsea*.

Darwinism Again.—A Darwin philosopher was brought before a justice on a charge of drunkenness. In defence, he said, "Your worship I am a Darwinian, and I have, I think, discovered the origin of my unfortunate tendency. One of my remotest grandfathers was an anthropoid of a curious turn of mind. One morning, about 4,391,633 B.C., he was looking over his store of Cocoanuts, when he picked up one for his breakfast in which the milk had fermented. He drank the liquor and got gloriously drunk, and ever after he always kept his Cocoanuts until fermentation took place. Judge, then, whether a tendency handed down through innumerable ancestors, should not be taken in my defence." Casting a sarcastic look at the prisoner, the justice said, "I am sorry that the peculiar arrangement of the atoms of star dust resulted in giving me a disposition to sentence you to pay a fine of five shillings and costs."

LARGE forests of the India-rubber tree have been recently discovered in Columbia, near the river Chucumagne.

THE HOUSEHOLD.

VARIOUS WAYS OF COOKING APPLES.

THERE is no article of food which can be prepared in such varied ways, and in such palatable dishes, as Apples. Whether eaten raw or cooked, this fruit is generally popular, and is equally desirable and nutritious for young and old; it may therefore be desirable to direct attention to some of the different ways in which it may be used. Apples that are to be employed for sauce should be pared, cored, and put into cold water unless cooked directly, to keep them from discolouring. Add a little water, cover closely, and cook gently, not stirring them until the whole are softened, or you will cook them in lumps; when soft, stir and mash, add a little butter, sweeten and strain through a colander.

Apple Souffle.—Stew the Apples as directed for sauce, adding a little grated Lemon peel and juice, and omitting the butter; line the sides and bottom of a baking dish with them. Make a boiled custard with one pint of milk and two eggs, flavouring with lemon and sweetening it to taste. Let it cool, and then pour into the centre of the dish. Beat the whites of two eggs to a stiff froth (they can be left out of the custard), spread them over the top; sprinkle white sugar all over them, and brown in the oven. The stewed Apple should be about half an inch thick on the bottom and sides of the pudding dish.

Apple and Tapioca Pudding.—Soak overnight a quarter of a pound of Tapioca; in the morning pour off the water, and add one quart and a gill of boiling water, sweeten, and flavour with grated Lemon peel and the juice of one Lemon. Take six or eight tart Apples, pare, core, and place in a pudding dish; fill the centre of each Apple with sugar; then pour the liquid Tapioca over the Apples, filling the dish, and bake in a hot oven until the Apples are perfectly soft. Serve cold with cream. If preferred, the Apples can be sliced into the Tapioca. If one desires to prepare it in haste, turn cold water on to the Tapioca, let it soak for fifteen minutes, then pour boiling water on, and stir it until it looks like thin starch.

Apple Meringue.—Pare, core, and stew ten good sized Apples in as little water as possible; sweeten and add a small piece of butter, put into a pudding dish, cover the top with the beaten whites of four eggs, sprinkle them thickly with powdered white sugar, and brown in the oven.

Apple Dumpling.—Make a nice crust, line a quart bowl with it, battering it well; fill up the bowl with sliced Apples, sugar, grated Lemon peel, and Lemon juice. Cover with the crust, pinching the edges close together, flour a thick cotton cloth, and tie it closely over the top of the bowl, and set it into boiling water, but not enough to cover the top of the bowl. Boil two hours, not letting the water go below the boiling point, and keeping it well filled in as it evaporates. Serve with a sugar and butter sauce, or with sugar and cream.

Apple Pudding.—Grate ten large Apples, paring them first; add to them four table-spoonfuls of melted butter, eight of sugar, grated peel and juice of one Lemon, and the yolks and whites of six eggs beaten separately. Line a dish with puff paste, and bake like a custard pudding.

Apple Cobbler.—Pare, core, and slice twelve large tart Apples, add to them the juice of two Lemons, grated peel of one, sweeten to taste; stew very slowly for two hours; turn into a mould. When cold, serve with cream.

Apple Float.—Take one pint of stewed Apples; sweeten and flavour to taste. When cold, and just before you desire to serve, add the beaten whites of four eggs, stir thoroughly into the Apple; serve with cream and sponge cake.

Apples and Rice.—Core and pare as many Apples as will fill a pudding dish, stew them so that they are nearly soft. Boil half a teacup of Rice; when nearly soft, add sugar, salt, and a pint of milk. Place the Apples in the pudding dish, turn the Rice over them, filling up the core of each Apple with sugar before putting in the Rice. Bake until it is a nice brown. Serve with cream, or without any sauce.

Another Rice and Apple Pudding.—Boil two large spoonfuls of well washed rice in a pint of new milk; slice into it while boiling two or three Apples, pared, and a few currants or raisins. Simmer slowly until the rice is very soft, then add one well-beaten egg. Stir for a few minutes, and serve with cream and sugar, or a butter and sugar sauce.

Apples in Imitation of Ginger.—To three pounds of very hard Apples, take two pounds of loaf sugar, and a quarter of a pound of best white ginger. Put these in layers (having first sliced the Apples in eight pieces and cored them) alternately in a wide-mouthed jar. Next day infuse an ounce of white ginger, well bruised, in about a

pint of boiling water; let it stand till next day. Then put the Apples, that have been two days in the ginger, into a preserving kettle, and turn over them the water from the bruised ginger. Simmer slowly until the Apples look clear. Take great care not to break the pieces. If closely covered, over a slow fire, half an hour will cook them enough, without needing to stir them. Put into jars, and cover tightly while boiling hot. Let the bits of ginger remain in the syrup until it is served.

Rice and Apple Souffle.—Boil two table-spoonfuls of rice in half a pint of milk; add, when soft, the yolks of two eggs, and sugar to taste. Make a wall with it around the sides of the dish; stew some pared and cored Apples until soft, fill the centre of the dish with them, fill up the apertures in the Apples with candied sweetmeats or jelly, and cover the whole with the whites of the eggs, beaten to a stiff froth, and sprinkled thick with white powdered sugar. Brown in the oven, and serve with cream.—*Cultivator*.

Fruit in Tin Cans.—An impression prevails among those who freely use fruit put up in tin cans, that it is injured thereby, and this impression is in many instances correct. We have long contended that all preserved fruits and vegetables should be stored in glass, and that no metal of any kind should be brought in contact with them. All fruits contain more or less vegetable acids, and others that are highly corrosive are often formed by fermentation, and metallic vessels are considerably acted upon. Tin cans are held together by solder, an alloy into which lead enters largely. This metal is easily corroded by vegetable acids, and poisonous salts are formed. Many persons (according to the *Boston Journal of Chemistry*) are greatly injured by eating Tomatoes, Peaches, &c., which have been placed in tin cans.

Culinary Uses of the Papaw in Tropical Countries.—Your description of the Papaw in a late number of THE GARDEN, reminds me of what a treasure it is to the *cuisine* in a tropical climate, where meat cannot possibly be hung up to make it tender. In the West India Islands, where the Papaw abounds, its leaf or its fruit (I am not sure which) is rubbed well into the meat about to be cooked, and tenderness, otherwise unattainable, is produced at once. The leaf of the Papaw has a curious kind of odour, reminding me of our Fig-leaf's scent; perhaps, therefore, an infusion made from Fig-leaves might be of similar efficacy. I certainly have heard in the County Wicklow, of a turkey having been rendered tender by suspension in a Fig tree.—A. L., Bala, North Wales.

Fruit Eating.—A very mistaken idea found a lodgment in the minds of many, otherwise sensible persons, to wit, that summer complaints, the generic term under which the disorders peculiar to the season are known, are caused mainly by the use of fruit, and that the wise and safe plan is to prohibit its use altogether. This method, which neglects to take advantage of one of the most beneficial provisions for man's use, is detrimental to health. When fruit does harm, it is because it is eaten at improper times, in improper quantities, or before it is ripened and fit for the human stomach. A distinguished physician has said that if his patients would make a practice of eating a couple of good Oranges before breakfast, from February till June, his practice would be gone. The principal evil is that we do not eat enough of fruit; that we injure its finer qualities with sugar; that we drown them in cream. We need the medicinal action of the pure fruit acids in our system, and their cooling, corrective influence.—H.

NOTES AND QUESTIONS ON THE HOUSEHOLD.

Carrot Jam.—Boil a few Carrots quite tender, rub them through a cullender, afterwards through a sieve, and to 1 lb. of pulp add 1 lb. of lump sugar, boil it to a jam, and when nearly cold add the juice of two Lemons (strained from the seeds), and the rinds grated very fine, to that quantity of pulp. Choose deep-coloured Carrots.—L.

To Dry Plums.—Gather the Plums when not too ripe. Prick each one with aarning-needle in several places. Take half a pound of sugar to each pound of fruit. Melt the sugar with a little water; skim it thoroughly; then add the Plums, and boil for half an hour. Lift out the Plums, and boil the sugar for twenty minutes longer, or until it nearly candies, which you can tell by taking up a small quantity in a spoon and letting it drop down until it threads out in strings. Turn it over the Plums, and put them to dry in a cool oven, stirring them up every few minutes. When candied, put into boxes.

Walnut Jam.—Walnuts, taken in the same stage as that in which they are used for pickling, and made into jam, are an excellent laxative. The following is the recipe for making the jam:—Take fifty Walnuts in which the shell has not begun to form, prick them all over, and boil them in water till quite soft; strain the water off, put a clove in each, and stew them over two ounces of bruised ginger. Make a syrup of half-a-pint of water and two and a-half pounds of coarse brown sugar, stirring on the fire till all is melted; then put in the Walnuts and boil for twenty minutes, stirring to prevent them burning.

THE GARDEN.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

THE ROSES OF 1874.

WHEN the rosarian has carefully selected his Briar or Manetti stocks, and has planted them in rich soil, and in a favourable site; when he has seen them break luxuriantly in the following spring, and in the summer has "budded" upon them the varieties which he loves the best; when, some eight months afterwards, he has watched, in gladness of heart, the "eyes" swelling and bursting into life, the development of the leaves upon the straight strong stem (as round and as smooth as a ruler), the robust young bud atop—that egg which holds the loveliest of Flora's birds; and when, upon a clear, cold, cloudless night, somewhere about the 20th of May, he goes to bed, hopelessly sure that, waking to-morrow he will find every one of those delicate darlings crippled beyond recovery by frost—well, I will content myself with observing, lest I should be tempted to use violent language, unbecoming a peaceful florist, that the rosarian in question should refrain from presenting himself at this particular epoch of his existence as a study for the photographic artist, and that any friend of his, desirous of negotiating with him a considerable loan of money, had "better bide a wee." For a brief period the rosarian, usually the most agreeable of men, is not good company. The blackness, which has discoloured his Walnut trees, seems to have fallen upon his visage also, and not only in his Potatoes, but in his personal mien, we may discern a limpy droop. This great discouragement has come upon him with disastrous consequences in the last two summers, and never, I think, more generally or more grievously than in this present year. With the exception of mural Roses, which were sufficiently protected and sufficiently advanced to resist the vernal frosts, and which (Maréchal Niel and Souvenir d'un Ami, specially) produced their flowers in perfection, I have seen no Roses this season in their complete integrity. We have had Roses bright in colour and Roses symmetrical in shape—no lack of those flowers which we rosarians term "nice, pretty, little blooms," but the Rose in her royal grandeur has been nowhere seen. Having won the only silver cup for which I have contested, against growers of reputation, and having seen the Roses of our chief exhibitors, I know that my own have been as good as those of other folks, and their shortcomings, as to substance, may be gauged from the fact, that my victorious collection of three dozen were very comfortably accommodated in a box, which, on many happier occasions, I have seen well filled by two. And I would suggest, *en passant*, a hint for young exhibitors—never make a small boy ridiculous by putting upon his head a man's large wobbling hat; show your bantams in a diminutive basket, and your little Roses in a little box. Reverting to the season—although untoward, it has brought us important teaching; and sweet may be the uses of adversity, if we will observe and act upon them. Just as misfortune reveals to us the fidelity and foudness of our true friends, so 9° of frost towards the end of May will surely indicate the constancy and constitution of those Roses which alone can withstand the eccentric severities of our English climate. We may safely assert that all Roses which, despite the frosts of the spring and the drought of the summer, have worn an attractive, or even a respectable, appearance in the year 1874, are as weather-proof as Roses can hope to be, and should be found, accordingly, in every Rosarium, chosen first as maids of honour and ladies in waiting to attend upon the queen of flowers. I will, therefore, name, for the information of those who have not had any opportunities of acquiring it, the Roses which have most distinguished themselves in the perilous conflicts of our last campaign; and I strongly advise any young amateur, who is forming a collection, and may read these lines, to order them one and all. Alfred Colomb has shown that magnanimity in affliction which characterised his regal namesake, and though looking somewhat thinner than usual, and wearing sombre

purple instead of vivid scarlet, has been "every inch a king." No other Rose, among the As, has been Al, except Abel Grand, which has retained all the freshness of its clear pink complexion and all the fullness of its form. The Baroness Rothschild has been Queen of the Bs, "looking more like her own daughter" (as was said of Mrs. Nickleby by one of her lovers) in her diminished size, but, as ever, fairest of the fair. Not many great guns in the C battery—Camille Bernardin, Charles Lefebvre, Centifolia Rosea, Chabillant, and others hanging fire or bursting ingloriously. The best have been Countess of Oxford, a large well-shaped, rich-coloured Rose; and the pretty, pink, waxy, Tea-scented Catherine Mermet. Our old friends Caroline de Sansal and Celine Forestier have also been attractive as garden Roses. Doctor Andry and Dupuy Jamain have been best in the D division, but neither of them in true character. The Climbing Devonensis has been, and promises to be, very beautiful. Pursuing our alphabetical survey, we come now to four of the best Roses of the year, an admirable quartette in the key of E. Etienne Levet has been the finest bloom which I have cut this summer, and is, in my opinion, the most valuable of our recent acquisitions. I have budded it "in four places," as auctioneers say, when the bidding is brisk. Emilie Hausburg has bravely maintained, against bitter frost and broiling heat, her form and complexion; also Edward Morren has kept his symmetry though not his size; and Exposition de Brie, though disturbed in toilette by the inclement weather, has glowed with brilliant tints. François Michelon has now won his spurs (or spines) as a Knight of the Rose, and should have a place wherever Roses grow; and Felix Genaro has been one of the few who have presented themselves at the roll call in tolerable preservation after the great battle against General Frost and General Drought. Surely dear old Gloire de Dijon, "Glory de John," as cottagers name it, may complacently paraphrase Tennyson's "Brook":

Roses come, and Roses go,
But I bloom on for ever.

There is a plant, growing upon the church wall at Caunton, and fast growing into a timber tree, which had many hundred beautiful Roses upon it in the month of May, which has now several excellent flowers, blooming at intervals, and which will continue its inflorescence until December. I rejoice to think, when I contemplate this tree, that, however fidgetty and destructive the people and the Parliament may be, there are certain institutions which they never can disestablish, and that one of these is—Glory de John! S. REYNOLDS HOLE.

(To be continued.)

HOW MARKET-GARDENERS MANAGE MUSHROOMS.

Most people are acquainted with the mode of growing Mushrooms in sheds, cellars, tunnels, or in regular Mushroom-houses; but it is astonishing how few, even among gardeners, know anything about the way in which Mushrooms are grown for market. Between the end of September and April immense quantities of Mushrooms are disposed of, three times a-week, in Covent Garden, all of which are grown in the open air. Mushroom growing is, however, a somewhat uncertain matter in bad seasons; but, under favourable circumstances, if the ridges on which they are grown are in good order, they form one of the most remunerative crops. Mushrooms for market are all grown on ridges of manure, moulded over as in the case of indoor beds, and covered with a layer of loose litter, which is generally all the protection they get. They are built so as to form a series of successive ridges from 20 feet to 100 yards in length, and 8 feet apart from the centre of the one to the middle of the next. An open sheltered position is the most favourable for them, but they are also often made along the intervals between rows of fruit trees, where they do remarkably well. The manure used for making them is ordinary stable-dung, from which the most strawy portion has been shaken out with a fork, and laid aside for covering the beds when completed, or for other purposes, and turned once or twice so as to sweeten it, and prevent it as much as possible from heating; for, the fresher it is when used the more dependence there is on it. When the manure has been prepared the

ground is selected, levelled, and cleared of all other crops. It is then lined off into breadths 6 feet apart, with a space of 2 feet between them, lines being drawn with a hoe, and wooden pegs, from 2 to 3 feet long, inserted firmly in these lines a few feet apart, to mark the place after the hoe-lines have been obliterated by trampling and wheeling barrows across them. The manure, being now moderately short, sweet, and fresh, is carted alongside the selected piece of ground, if it has not been previously prepared there, and some men are then set to wheel it along the rows, whilst others build it very firmly into ridges with forks. It is the 2-feet wide space that forms the basis of the ridges, which are made at first about 2 feet high, or a little more, and bluntly tapered towards the top. They are then left exposed for some days before being spawned, so that the heat may subside to about 80°, which is readily determined by sticks inserted in the litter being drawn out and felt with the hand. If the heat gets strong, the ridges are immediately turned down, so as to form two out of the one, in order to cool the manure and prevent a violent fermentation. This is no uncommon occurrence, for we frequently see whole fields in August and September so overturned after having been put right. Now the use of the pegs is more than ever apparent, for they prove infallible guides, without any additional trouble, in lining off for the reconstruction of the ridges. When the heat has subsided to a proper temperature the beds are spawned on both sides. Market gardeners formerly made their own spawn, but now they find that they can purchase it much cheaper than they can make it, consequently they buy their spawn. They break the cakes up into pieces from 2 inches to 3 inches square, and these are inserted in three rows along each side, placing them pigeon-hole fashion, and from 9 inches to 1 foot apart in the rows. After being spawned, a layer about 3 inches in depth of mould is placed over the manure, and made very firm thereon by means of beating with the back of the spade; indeed, the ridges are commonly now watered through a water-pot rose, and again beaten very firmly and the surface left smooth and even. All is now left alone for a few more days, when, if the inside is not likely to get too hot, a loose covering of litter is applied over them, and increased in thickness a short time afterwards. This completes the ridges, which usually come into bearing about eight or ten weeks after being spawned. The first ridges are made about the end of July and 1st of August, and the main series in the latter part of August, and in September, whilst some are made as late as October. It is not altogether to form a succession that the ridges are made at intervals, but because it would be a difficult matter to get fresh dung sufficient to make many beds at one time, nor could the labour be conveniently spared all at once. Moderately dry and frosty winters are very beneficial to the Mushroom crop, but dull and damp weather is equally detrimental, hence the great risk they incur. Mr. Steel, of the Fulham Fields, informs us, that he once knew a most successful Mushroom grower, a friend of his own, to lose as much as £500 in one season, owing to the failure of the crop by reason of bad weather. Last year many of the growers did not nearly clear their expenses, because the winter was a continuous dull and rainy one, which soon rotted the spawn and rendered the ridges barren. In hard frosty weather additional protection is applied in the way of more litter, and to guard against wet, the beds are covered with mats pegged on either side with old Tomato stakes, or held in place by means of boards, stones, slates, bricks, or any other heavy materials; the same protections are also used to prevent the strawy litter from being scattered by the wind. The frost can thus be excluded, the wind prevented from doing irreparable damage; but, notwithstanding all these coverings, the cold rains find their way to the interior, and act with deadly effect upon the spawn. Even before the beds are spawned, and after that time and before being moulded over, they are covered with mats to exclude wet. We never yet knew out-door beds to be artificially watered, except at moulding time; nor yet have we seen them in a bearing condition at midsummer. In gathering the Mushrooms the rank litter is carefully removed by one man, and after him come others with baskets in which the Mushrooms are put, and following the pickers is another man replacing the covering, for it is an important point not to permit the ridges

to become much exposed at any time. After April, or the 1st of May, they are seldom any good, consequently they are then uncovered and entirely removed to be spread on some piece of ground about to be dug over, or carted into one solid heap to await such an opportunity of being committed to the soil. This manure, being thoroughly decayed, is in excellent condition for feeding gross and quick growing plants, such as Vegetable Marrows, Tomatoes, Lettuces, Cauliflowers, Celery, or French Beans, and is much relished by them. Mr. Geo. Steel, however, instead of removing his Mushroom beds as soon as they become exhausted, uncovers them and plants his earliest Tomatoes on either side of them, and, as they advance in growth, he pegs them to the ridges. As this is a warmer place for Tomatoes than the open border, Mr. Steel generally gets ripe fruit from them a week earlier than he does from any other plants in his extensive range of garden ground. Mr. Dancer, of Chiswick, grows Mushrooms in ordinary frames, and sometimes with extraordinary results. In autumn, winter, or spring, the Mushrooms do well grown in this way, but in the summer time they do not repay the trouble and cost incurred in producing them; for, Mr. Dancer tells me, they come up small, scantily, and irregular, and no sooner do they appear above the surface than they turn bad, no matter how carefully tended. His mode of culture is as follows:—Good fresh litter is selected, laid in a heap, and turned, to sweeten and ameliorate it. A trench is then cast out as for a Cucumber bed, 5 feet wide, and 2 feet deep, and this is filled with the prepared manure, which, after it has subsided to a proper temperature and wooden frames placed thereon, is spawned, and afterwards earthed over with 2 inches deep of mould. The sashes being thus put in position, are covered over with two or three folds of mats or a 4-inch thick layer of litter, held in its place by means of boards laid across it. In these frames, so darkened, the Mushrooms appear in two months or less, and continue in good bearing for the next three or four months. Mr. Livermore (Mr. Dancer's foreman) informed me that from one plot of these frames, including four large sashes, he gathered four half-sieves of Mushrooms in one week. This bed, instead of having the fermenting material buried in a trench, was built above ground, precisely in the same manner as a common hot-bed, and was little shaded by the neighbouring fruit trees. F.

HERB CULTIVATION AT MITCHAM.

MITCHAM has long been celebrated for its herb fields, from which the London herbalists derive their Mint, Sage, Liquorice, and similar herbs. Of these, as a rule, distillations are made by the growers, and they are disposed of in a semi-refined condition, or the herbs themselves are brought into market as soon as they are harvested.

Chamomile.—To this several acres are devoted, the double-flowered kind being preferred on account of the weight of the produce; but both single and double sorts are grown. In March, old and somewhat "spent" plantations are broken up and the plants divided into good-rooted slips, which are planted in well prepared ground in rows 2½ feet apart, and 2 feet asunder in the rows. A common practice, however, is to plant as thick again as this, and to thin out the plants afterwards to the distances just named. The plantations are intercropped with Lettuces in spring. As soon as the blooms begin to expand, they are fit for gathering, and from that time, as long as they yield sufficiently to pay, the flowers are gathered several times in a season by women, who are either paid a regular day's wage, or a penny, or thereabouts, per pound for picking.

Lavender.—This is extensively cultivated at Mitcham, both farmers and cottagers bestowing special attention on it; and this district presents a lovely sight in the last fortnight of July, when the different fields of it are in full bloom, the air for miles around being loaded with its fragrance. Lavender is increased by means of rooted slips, planted out, in rows about 18 inches apart and half that distance asunder, in March or April. Sometimes the sets are planted as wide in the row as the drills are apart. For the first year the produce amounts to but little; and, therefore, Parsley or Lettuce is planted between the rows. As soon as the plants have grown sufficiently to become crowded, every alternate row, and also every alternate plant in the rows left, are lifted—say in spring—and transplanted into another field, so as to form a new plantation. Thus the plants stand 3 feet apart each way, or 3 feet one way and 18 inches the other.

Coleworts, Lettuces, or other early and quickly matured crops, are raised amongst the lavender in the early part of the year; but, after June, all such catch-crops are removed. The flowers are usually harvested in the first fortnight of August, and, as has been stated, are distilled at the farm on which they are grown.

Liquorice.—This was once largely grown at Mitcham, but although it is still grown in considerable quantities, it is not now so extensively cultivated there as formerly, on account of the cost attending its culture. It entirely occupies the ground for three years, and during that time requires great attention in the way of cleaning, besides the ultimate cost of trenching out the roots, or rather, underground stems. The ground being deep, is heavily manured in autumn or winter, when it is trenched and laid up in ridges, in a rough state, till spring. It is then levelled, marked off in drills about 2 or 3 feet apart, and some 3 or 4 inches deep, and in these the sets are planted in March. The sets consist of finger-length pieces of the old root-stems, each containing an eye or two. During the first year the ground is usually intercropped, as is also the case in the earlier portion of the second year; but after the middle of the second summer, and throughout the whole of the third year, the Liquorice requires all the room. When the stems are matured in the autumn of each year, they are cut over close to the ground, and if time can then be spared, the soil between the rows is forked over, some well-decayed manure being occasionally worked into it at the same time. The lifting of the crop, which usually takes place in the end of the third season, is a difficult operation, involving much labour. A deep trench is cast out, lengthways, alongside the first row, and by means of forks, pulling-ropes being even sometimes employed, the root-stems are extracted. In this manner the whole of the rows are treated, until all are successively lifted. The roots may then be stored in sand or pits, like Beets, Carrots, or Potatoes. Growers of Liquorice do not always harvest the crop; on the contrary, they sometimes sell it as it stands in the field, and the purchaser lifts it himself.

Mint.—Both Spearmint and Peppermint are largely grown at Mitcham, particularly the latter; indeed, this crop ranks second in importance only to Lavender. It is first planted in rows 13 inches apart each way, and in the end of the next two seasons it is ploughed in. The plantations are kept free from weeds during the summer by means of hoes; and about the end of the first week, or during the second week of August is the usual time for cutting Mint for distillation. In the Fulham Fields, and in other districts in which market-gardening is carried on, Mint is largely grown for sale in a green state. For this purpose the dampest piece of ground is selected for its culture, if it is to be a permanent plantation, but it will grow in almost any soil. It is planted in rows a foot apart, and the ground is intercropped the first year, but afterwards it runs through the soil in such a way that it becomes a complete mass of under-grown stems and roots. It is cut and bunched for market as required, the greatest demand for it being during the Pea season. It is also forced in large quantities. I have seen a range of 43 light frames filled with Mint alone. These beds are made up in December or January, when the ground they occupy is excavated to a depth of 20 inches, and filled in with fermenting manure packed firmly. A few inches deep of soil are then added, and in this the Mint roots are thickly planted. Livings of manure are also placed round the frames, the sashes during the night and in cold days being also covered with it.

Poppies.—Of the white kind several acres are grown. They are sown in rows in spring, some 20 or 24 inches apart, and require no further care, beyond a little thinning and cleaning, till August, when their seeds ripen.

Sage.—This forms an important crop, which, under favourable circumstances, is pretty remunerative; the stalks being cut over, bunched, and sent to market at once. New plantations are formed with rooted slips, obtained by dividing the old plants; they are inserted, late in spring, in rows 1 or 2 feet apart, and about a foot asunder in the row. During the first season Parsley or Lettuces form an inter-crop, which also occupies the ground during the earlier part of the succeeding ones. Except hoeing and cleaning, the plantations need no care so long as they continue in a thriving condition; and, when the lines get broken, and blanks and sickly plants occur, the plantation is broken up. Both the reddish and green-leaved kinds are cultivated.

Squirting Cucumbers.—These are raised in frames, like Vegetable Marrows, and are planted out, about the end of May, in rows some 4 or 6 feet apart, and 4 feet asunder in the row. They flower and fruit at the same time, and the fruits are gathered before they are ripe, otherwise a mere touch would burst them. The fruits are usually distilled by the growers.

NATURAL SELECTION.

In this matter Nature (says Prof. Tyndall, in his address delivered before the British Association at Belfast) gives the hint, man acts upon it, and by the law of inheritance exaggerates the deviation. Having thus satisfied himself by indubitable facts that the organisation of an animal or of a plant (for precisely the same treatment applies to plants) is to some extent plastic, he passes from variation under domestication to variation under Nature. Hitherto we have dealt with the adding together of small changes by the conscious selection of man. Can Nature thus select? Mr. Darwin's answer is, "Assuredly she can." The number of living things produced is far in excess of the number that can be supported; hence at some period or other of their lives there must be a struggle for existence? and what is the infallible result? If one organism were a perfect copy of the other in regard to strength, skill, and agility, external conditions would decide. But this is not the case. Here we have the fact of variety offering itself to Nature as in the former instance it offered itself to man; and those varieties which are least competent to cope with surrounding conditions will infallibly give way to those that are most competent. To use a familiar proverb, the weakest goes to the wall. But the triumphant fraction again breeds to overproduction, transmitting the qualities which secured its maintenance, but transmitting them in different degrees. The struggle for food again supervenes, and those to whom the favourable quality has been transmitted in excess will assuredly triumph. It is easy to see that we have here the addition of increments favourable to the individual still more rigorously carried out than in the case of domestication; for not only are unfavourable specimens not selected by Nature, but they are destroyed. This is what Mr. Darwin calls "Natural Selection," which "acts by the preservation and accumulation of small inherited modifications, each profitable to the preserved being." With this idea he interpenetrates and leavens the vast store of facts that he and others have collected. We cannot, without shutting our eyes through fear or prejudice, fail to see that Darwin is here dealing, not with imaginary, but with true causes; nor can we fail to discern what vast modifications may be produced by natural selection in periods sufficiently long. Each individual increment may resemble what mathematicians call a "differential" (a quantity indefinitely small); but definite and great changes may obviously be produced by the integration of these infinitesimal quantities, through practically infinite time. If Darwin, like Bruno, rejects the notion of creative power acting after human fashion, it certainly is not because he is unacquainted with the numberless exquisite adaptations on which this notion of a supernatural artificer has been founded. His book is a repository of the most startling facts of this description. Take the marvellous observation which he cites from Dr. Craiger, where a bucket with an aperture, serving as a spout, is formed in an Orchid. Bees visit the flower: in eager search of material for their combs they push each other into the bucket, the drenched ones escaping from their involuntary bath by the spout. Here they rub their backs against the viscid stigma of the flower and obtain glue; then against the pollen-masses, which are thus stuck to the back of the bee and carried away. "When the bee, thus provided flies to another flower, or to the same flower a second time, and is pushed by his comrades into the bucket, and then crawls out by the passage, the pollen-mass upon its back necessarily comes first into contact with the viscid stigma," which takes up the pollen; and this is how that Orchid is fertilised. Or take this other case of the *Catasetum*. "Bees visit the flowers in order to gnaw the labellum; on doing this they inevitably touch a long tapering sensitive projection. This, when touched, transmits a sensation or vibration to a certain membrane, which is instantly ruptured, setting free a spring, by which the pollen-mass is shot forth like an arrow in the right direction, and adheres by its viscid extremity to the back of the bee." In this way the fertilising pollen is spread abroad. It is the mind thus stored with the choicest materials of the teleologist that rejects teleology, seeking to refer these wonders to natural causes. They illustrate, according to him, the method of Nature, not the "technic" of a man-like artificer. The beauty of flowers is due to natural selection. Those that distinguish themselves by vividly contrasting colours from the surrounding green leaves are most readily seen, most frequently visited by insects, most often fertilised, and hence most favoured by natural selection. Coloured berries also readily attract the attention of birds and beasts, which feed upon them, spread their matured seeds abroad, thus giving trees and shrubs possessing such berries a greater chance in the struggle for existence.

In Sweden gardening forms a part of the educational system. Upwards of 2,000 schools have gardens for planting attached to them, and the teachers of elementary schools are obliged to learn gardening.

NOTES OF THE WEEK.

— *BRUGMANSIA SANGUINEA*, Mr. Ellacombe informs us, is now flowering very freely in his garden at Bitton, near Bath, the plants having remained in the open air unprotected for the past dozen years.

— THE plants called Loco and Rattleweed in California, and which have proved destructive to large numbers of horses and cattle which had eaten them, are pronounced by Dr. Gray to be *Astragalus Hornii*, and *Astragalus lentiginosus* var. *Fremontii*.

— MUSHROOMS spring up in a night and cover meadows and pastures so plentifully that the business of gathering them has lately been quite brisk. Cheap as they have been on account of their superabundance, many of the Mushroom-gatherers have made considerable sums of money.

— MR. ELLACOMBE informs us that the *Eucalyptus cordata* which grows against Mr. Symes's house at Balmuto, Kirkealdy, fruits and flowers freely, and reaches to the top of the house. As we have not noticed *E. globulus*, the much-talked-of fever Gam tree, display such vigour in the south of England as *E. cordata* does in Scotland, it is probable that the last-named plant is most suitable for cultivation in this country.

— At Abney Hall, Cheadle, the residence of Sir James Watts, there is now in flower a plant of the Dove Orchid, bearing six spikes of flowers. Although said to be comparatively seldom met with in blossom, it flowers annually at Abney Hall, where it is treated in no way different from other stove plants. Its flowers are very interesting, and the so-called dove wings are especially pretty when viewed through a magnifying glass. Single flowers of this plant, mounted on wires, are found to be useful for bouquets.

— THE French husbandmen may rejoice (*Galignani* remarks), as the *Phylloxera* seems disposed to amend its ways, if not to disappear altogether. The following interesting information on that subject is from the *Midi* of Nîmes, and seems of a character to encourage Vine-growers. M. Monrret writes thus to that journal:—From all sides, and from the men most competent to judge, I hear it said that many Vines considered as dead are returning to life in our arondissement.

— MUCH has been said at various times in praise of *Eucharis amazonica*, but not one word more than it deserves. At Abney Hall, Mr. McKeller, has three plants of it under his care at the present time, beautifully in flower. On the first plant there are thirty-nine spikes or flower-heads; on the next, thirty, and on the third, twenty-seven heads. Before the plants threw up their flower-spikes, they were kept dry for a considerable time, but not so dry as to injure the health of the foliage. There seems to be no difficulty in growing this plant and flowering it well, and it is one of the most beautiful of *Amaryllidaceous* plants.

— MR. CHARLES MOORE, who recently brought a good many valuable and very novel plants to this country from the South Sea Islands and Australia, returns to Sydney by the next mail, having visited many of the best botanic gardens and nurseries in Europe, and selected an immense collection of valuable and rare plants for the Sydney Botanic Garden, which is said to be one of the most beautiful in the world. Mr. Moore, whom many of our readers will know as the brother of Dr. Moore, of Dublin, informs us that he was everywhere most kindly received, and that both directors of botanic gardens and the chief European nurserymen placed their collections at his disposal.

— THERE is now coming into bloom, for the second time, in the open border, at the gardens of the Royal Irish Society, at Glasnevin, near Dublin, a most beautiful deep rose-coloured variety of the *Crinum* family, figured without description (which was lost in going through the post) in the number of the *Botanical Magazine* for the current month, and raised by the learned Curator of the Gardens, Dr. David Moore, from seed received from the higher mountains of Natal. This plant has now withstood the Dublin winters without any protection for the last four years, and may thus be considered perfectly hardy in this country, as the Dublin climate in winter is quite the reverse of mild. This plant is likely to be a grand acquisition to our hardy plants.

— Two new flower markets were opened in Paris this month. One of these occupies all the *Avenue des Fernes* between *Avenue de Wagram* and the *Rue des Acacias*, and contains ninety-one places of six square metres each; it is to be open on two days in the week. The other is in an open space at *Osprey*; it contains ninety-nine places of the same dimensions, and is to be open three times a week. The rent for one of these places is only equal to sixpence a day, with a charge of fourpence per month extra for sweeping, &c. The two markets will consequently bring in to the city funds between four and five pounds each day that they are open. These markets are constructed in the simplest manner, with light roofs supported on thin iron colonnettes, or moveable standards, according to the

nature of the locality, and while they give a great air of gaiety to the city they supply employment to a large number of persons. Would not Trafalgar Square and others of our open spaces be very suitable for flower markets of this kind?

— MR. PULHAM is engaged in the construction of several very extensive rock-gardens in the north—at Smithall's Hall, Bolton, at Hutton Hall, Gisborough, and at Pierremont, Darlington.

— THE lovely little Irid *Anomatheca cruenta* is well worth the attention of those who have dry gravelly banks or rock-work to decorate. It lasts long in bloom and is quite hardy in situations such as those just indicated. Plants of it have been finely in flower at Messrs. Hooper's, Covent Garden, during the past month.

— THE singularly beautiful *Gladiolus brencleyensis*, by far the most effective in the tall-growing section, is now beautifully in flower in the cottage gardens all along the Suffolk coast. In Belle Vue Park, Lowestoft, there is a magnificent bed of it. The light sandy soil, both there and at Yarmouth, seems to suit both this and other *Gladioli* perfectly.

— THERE are now some remarkably fine examples of the new Potato "Climax," at Messrs. Hooper's, Covent Garden. It is a large handsome root, distinguished from many of the newer Potatoes by its good eating qualities, and is considered by many to be the best of all the new American Potatoes, so far as they have been as yet tried in this country.

— THE late spring frosts having spared some Shiraz Apricots, we have been enabled to taste this variety, and to confirm what has already been said of it. It is, without doubt, the best of all Apricots; its flesh, which is melting and sweet, has but little consistence. When better known the Shiraz must occupy a prominent place among Apricots; but it has one fault, and that is, it is not a handsome fruit on the table; it also travels badly. Nevertheless, it is a variety which no garden should be without. Such is M. Carrière's opinion of this Apricot, as given in the *Revue Horticole*. Do any of our readers grow it?

— It is stated that there are 2,300,000 Vineyard proprietors in France; that there are only eleven departments which do not grow the Vine; that twenty cultivate Grapes for home consumption, and fifty-one for export. Most of the fruit is intended for the wine-presses; but the best dessert Grapes also come from France. The famous Chasselas de Fontainebleau (Royal Muscadine) are grown in the two little townships of Thomery and Champagne. The Vineyards there produce an annual crop of about 2,000,000 pounds, of which the capital consumes about 1,000,000 kilogrammes, while the rest is exported to England, Austria, and even Russia. The trade in Grapes, foreign and home grown, amounts in value to several million francs a year. This, of course, does not include Grapes used for wine.

— THE August number of the *Florist* contains excellent coloured representations of two of the finest of the new hybrid Clematis raised by Messrs. Jackman & Son, of Woking. These are *Stella*, an eight-sepal variety, nearly white, with a band of purplish-lilac down the centre of each segment, and *Fair Rosamond*, a fine bluish-purple flower, the centre of the segments of which are tinted with claret-purple. There is also a second coloured plate containing three varieties of *Cyclamen persicum*, raised by Mr. Little, of Twickenham, a well-known amateur cultivator of *Cyclamens*, to which we have frequently alluded in THE GARDEN. These are *Royal Purple*, a fine massive flower of a rich purple colour; *Rose Queen*, also a fine variety, with purplish-crimson flowers; and *White Perfection*, a pure white-flowered form with nicely rounded segments.

— WE have lately seen some fine samples, grown by Mr. Knight, at Floor Castle, of *Mousteria deliciosa*, the very ornamental tropical Aroid, which is often classed among edible fruits. Its "prickles" must, however, prevent this ever taking a place as a useful tropical fruit. Many who know this merely as a fine foliage plant, or as a fruit-producer when grown in a warm humid atmosphere, may not be aware of its adaptability as a balcony plant during the summer months, and a useful decorative plant for a warm drawing-room or front hall during the winter season. It is often used along with some of its larger-growing allies as a sub-tropical plant throughout the summer, and has a noble appearance when tastefully grouped along with lighter and more graceful forms of vegetation. Just now a fine robust specimen is flowering freely in front of a confectioner's shop in Lowndes Square, where its great ivory-white spathes and bold lacinate foliage attract a large amount of attention from pedestrians. It is planted in a large square tub, and looks as if it had occupied that position for some years. When grown under cool treatment the plant acquires a short-jointed sturdy habit of growth, and does not extend so rapidly as when grown in a hot stove; nevertheless, it is none the less attractive, and deserves more general culture in the way suggested.

THE INDOOR GARDEN.

CULTURE OF THE GREAT WATER LILY.

(VICTORIA REGIA.)

THIS is one of the largest and most interesting of all tropical aquatics, although its indoor cultivation is almost necessarily limited to perhaps, less, than half-a-dozen gardens in this country, if we except Oxford, Kew, Sheffield, Birmingham, and other public gardens. Its culture with us is expensive, requiring a large house and tank from 15 to 30 feet in diameter, and a costly heating apparatus, to say nothing of minor details, all more or less troublesome and costly. In face of these facts, the question naturally arises, whether it would not be better to expend a hundred pounds annually on hardier plants, fine trees, fresh green lawns, or in the fruit garden, rather than expend twice that amount or more on the culture of a single plant, which, however beautiful, lasts only a month or two in perfection. No doubt, this question has occurred to many before, as the plant rarely finds a place in private gardens. Apart from its expensive surroundings, however, the indoor culture of this plant is very simple. Although not naturally an annual, it flowers much better when

to have the young specimen planted in a coarse basket of wicker-work, using a rich compost of sandy-loam and well rotted hot-bed manure. This basket and its contents would not take up much room in a shallow tub or tank in the plant stove, and when the mild weather arrived the plant could be gradually hardened off, and the basket and its contents might then be placed in a suitable position in the open-air tank. The *Victoria regia* is readily propagated from seed sown during the winter months, or nearly as soon as it is ripe, and but little difficulty would be experienced in obtaining a plant, early in the spring months, for experimental purposes, from Kew, Chatsworth, or other large garden where it is grown. The plant is a native of Guiana, where it occurs in the Parana River, and South America, being found abundantly in some of the sheltered tributaries of the Orinoco and also in those of the Amazon. In its native habitat the flowers acquire a richer rosy tint than in our hot-houses here at home, where it is a rarity to see more than one of its delicately-perfumed flowers open at the same time. The leaves of this species are frequently 6 feet, or even more, in diameter, and float on the surface of the water, being supported by a beautiful net-work of hollow veins. The under surface of the great table-like expansion is of a rich purple colour, the upper surface

Victoria regia in flower.

so treated in this country, and seedlings are raised every winter. These are simply planted out, in the spring, on a mound of richly manured compost, the temperature of the surrounding water being kept as near 80° as possible, by means of hot-water pipes which are conducted round the bottom of the tank. In order to keep the water fresh and sweet, some system must be adopted to secure circulation, and this may be obtained by having water constantly flowing into the tank on one side with an outlet at the other. Some cultivators employ a small overshot wheel, which is turned by the inflowing water, and at the same time keeps the whole body of the water in constant motion. This appliance is, however, not absolutely necessary, as the inlet and outlet pipes, with a constant supply of fresh water, is all that is requisite to ensure success. There are, however, many situations out-of-doors in which this plant will not only make a luxuriant growth, but produce flowers during the summer months. It has already flowered at several places in England, where tanks have been formed to receive the condensed steam from the engines of water-works or manufactories, and in favourable situations like these it deserves a fair trial. The main elements of success consist in having a strong healthy well-established plant ready for planting out in the latter end of May or beginning of June, and, in order to prevent the growth being checked, it would be advisable

being deep green. The plant is just now in bloom at Kew and elsewhere.

B.

DOUBLE CHINESE PRIMROSES.

THESE are more useful, though hardly more beautiful, than the single varieties. For pot plants the latter are as good as the former, and perhaps even more showy, and assuredly far easier grown. But they have a weakness for falling off the stems when cut for vases and bouquet work, whereas the double ones stick to their stalks well, and will keep a week or more in a damp bouquet, and at least a fortnight in water. They are also quite different in form, as, instead of a single flower, we have a ball—soft, lasting, pure—of white, purple, or other exquisite colour. As a rule—though a new race has of late years been introduced that may be held as more or less an exception—the double Chinese Primroses do not seed nor come from seed. They are perpetuated and propagated by division and cuttings, or Irish cuttings, as they are called—that is, single shoots with a small piece of root-stock adhering. If the latter are used, they should be potted deeply, so that the crown of the plant should almost rest on the soil. Such cuttings, with a root, cannot always be had without splitting the main stem of the plant into as many pieces as there are crowns. The modicum of root secured at the base of each piece is retained chiefly for a temporary object: it supports the plant until it emits fresh roots, just at the base of the

leaves. When this is accomplished, the lower roots and the lanky stem alike may both be dispensed with, and the plant treated like a cutting; or, if the old stem continues healthy, heals over soundly, and fresh roots are produced at the base, the whole may be left, and the plants potted on, with the old and new parts complete. But the old stem is likely to canker afterwards, and it is safer practice to remove it entirely with the knife, just under the main roots at the base of the leaves. If propagation by division is adopted, the plants should be earthed up right to the base of the leaves, as soon as they are out of flower, with light sandy soil, and encouraged to grow rapidly for a month or six weeks in a temperature of 55° to 60°. They must be watered sparingly, as the earthed-up stems are liable to rot. To facilitate the rooting of these shoots, it is well to peg each down separately, or even layer them. When rooted, shake out the plants and pot each shoot separately, and also make the most of the stem and bottom roots, if sound, by sub-dividing them, as already advised. Where large plants are desired, the plants may be treated as above, and then, when the branches left on the original plant are rooted from 3 to 6 inches, shift them into a larger pot; or the layering, &c., may be dispensed with, and the old plants simply potted into larger and somewhat deeper pots than before. In this mode of culture great care must be taken to have the drainage perfect, and also to use some crocks or pieces of charcoal around the old stem, as these plants are marvellously impatient of damp, especially in a dormant state, and stagnant water is sure and certain death to them at any time. These old crowns are apt to give way in the midst of their beauty, and for this reason I prefer making up a large plant, from a number of separate and independent ones, a month or so before they are wanted, to growing large plants as above. Besides, double Primroses never look better than in 6-inch or 8-inch pots; and, with good culture, a single crown may be grown large enough to furnish either in about ten months. Cuttings, to those who are pretty skilful propagators, is the most expeditious mode of increasing these charming Primroses. Perhaps the best method is to cut off the shoots, with about half an inch of heel under the leaves. Insert each separately in thumb-pots, well drained in pure sharp silver-sand. No stagnant water can rest in this medium. Place the pots in a light house or pit in a temperature of 55° to 60°, top and bottom, and see that no water is allowed to lodge in the crowns of the cuttings, and that the part in the pots is kept dry rather than wet. The base of the cutting must also be inserted firmly. In a month or five weeks they will be rooted and should at once be potted on, and grown throughout the season in a cool pit or greenhouse fully exposed to light and air, but not set in the eye of the sun nor the way of a draught. April or May, or as soon as may be after the plants cease blooming, is the best season for these modes of increase. Another simple mode of obtaining large plants is to reserve the latest and weakest of the plants struck one year; prevent them flowering, next season grow them on freely, and huge masses may thus be prepared for furnishing a 12-inch pot. But in such sizes rough lumps of peat and loam, and at least 2 inches of drainage must be used, to prevent the possibility of stagnation, with its consequent swift destruction. For the general stock a compost of equal parts loam, peat, and at least a sixth part of silver-sand, suits well. A small proportion of thoroughly rotted cow-dung is useful in giving colour and size alike to leaves and flowers. But it is safer to water occasionally with weak manure-water, as the unctuous nature of dung is apt to injure the free and open texture of the soil. As to varieties: For many years there were but two, the double white and the double purple, or rather lilac, for the purple was somewhat pale. A few years ago Messrs. Smith, of Dulwich, I think, introduced an improved set of double Primroses; and since then Messrs. Henderson and Son, and others, have raised or sent out many more, so that now we have quite a choice selection of double Primroses. Among these *Candidissima fimbriata plena*, King of Purples, *Magenta plena*, Gem, *Magnifica*, *Lilac Queen*, and *Magenta Queen*, are perhaps as good as most of them. For bouquet and vase-work, the old double white, which is easier grown than some of the newer varieties, is exceedingly useful. The semi-double varieties that are offered as coming true for seed are uncertain, and hardly worth the trouble. Better grow the best strain of single Primulas, and purchase plants of the finest double varieties, and propagate and grow them as above directed.—*Cornley*. [The following excellent selection of kinds is that of Messrs. E. G. Henderson, of St. John's Wood, who have a capital collection of these plants:—Double-flowered *Atro-rosea*, *Candidissima*, King of Purples, *Exquisite*, *Emperor*, Mrs. Eyre Crabb, *Magnifica*, *Rubra grandiflora*, *Blushing Beauty*, and *Princess of Wales*.—*Ed.*]

Large Cockscomb.—I have a Cockscomb which our local cultivators say is the best they have seen. Would some of your readers therefore kindly say if it is of more than ordinary size? It measures from tip to tip 2½ inches, and in depth over the crown 1½ inches. It is exactly its width that is remarkable. It was grown, I think, from a true seed, and it looks as if it would increase several inches yet.—JAMES SIMPSON, *Port Nisney, Broughty Ferry*.

THE GARDEN IN THE HOUSE.

DINNER-TABLE DECORATIONS.

Plants through the Table.

HAVING already described (see p. 101) the manner in which plants are put through the table, I shall now treat only of the floral arrangements round their bases, taking it for granted that the zinc trays are fixed in their proper places. Let us take the case of a dinner-table laid for sixteen persons. If the centre piece is a March vase, with a trumpet rising out of the upper tazza, it should be arranged thus:—In the bottom dish scarlet Cactus blooms and trusses of *Stephanotis* should be placed alternately with spikes of *Astilbe* (*Spiraea*) *japonica* and *Cyperus alternifolius*; around the edge, resting on the table-cloth, should be fronds of *Adiantum Farleyense* and *Pteris serrulata* alternately. In the top dish should be pale-flowered zonal *Pelargoniums*, Lily of the Valley, and Maiden-hair Fern; in the trumpet, *Astilbe* (*Spiraea*) *japonica*, *Rhodanthe Manglesii*, small-flowered scarlet and pale pink *Begonias*, Maiden-hair Fern, long-trailing sprays of *Lygodium*, and a few spikes of wild Grasses. The plants put through the tables should be Ferns (*Pteris tremula*), round the base of which should be arranged trusses of *Stephanotis*, white *Rhodanthe*, Maiden-hair Fern, and *Lastrea Felix-mas*. The baskets should be of glass, and might contain Grapes, two of white, and two of black, which should be set off with Ferns, a spray of *Lygodium* being also twined around the handle of each basket. There should be four oval glass dishes on the table, for Cherries and Strawberries. A Pine and Melon might be placed at top and bottom, which, like all the other dishes of fruit, ought to be decorated with foliage; between the baskets should be small circular stands or dishes for sugar. In front of each person might be a finger-glass, containing a button-hole bouquet, or coat-flower, of a colour to harmonise with those in the centre-piece, and on the surface of the water should lie double scarlet *Pelargonium* pips, and small leaves of the sweet-scented *Geranium*, called Lady Plymouth, the stem of each *Pelargonium* pip being inserted through the centre of the *Geranium*-leaf, so as to keep it firmly in its place. This table is suitable either for daylight or gaslight.

Groups of March-stands.

The lighter March-stands can be fitted, the greater is the effect produced, and for this purpose nothing is better than some of our wild field Grasses and Horse-tails; the foliage of *Asparagus* may also be usefully employed in decorations of this kind. I once awarded a first prize to a group of three stands ornamented after this fashion. Their forms were alike, with the exception of the centre-piece, which was the tallest, and which should always be the case where three stands are thus arranged. But few flowers were used in their decoration; and yet they were very beautiful, and much admired by all who saw them. The bases of the stands were concealed by a fringe of large Fern-fronds, on which were laid flowers of the showy *Eucharis amazonica* and the brilliant *Scarborough Lily* alternately. From among these the beautiful blue buds and expanded flowers of *Agapanthus umbellatus* peeped here and there; and the effect of the lower parts was still further enhanced by the judicious use of *Lagurus ovatus*, and other graceful ornamental Grasses. The tier above was fringed with Maiden-hair Fern (*Adiantum cuneatum*), beneath which drooped gracefully the beautifully formed blooms of both the rose and white-flowered *Lagerias*. The other flowers in this tazza were *Eucharis* and *Vallota*, with the addition of *Franseria calycina*, *Rondeletia speciosa*, and blue African Lily. The trumpet-shaped vases above were lightly filled with spikes of *Chelone barbata*, or scarlet *Pentstemon*, and light Grasses—the whole forming a most charming arrangement, and as good an example of a florally-dressed group of March vases as it would be possible to give as an illustration.

Decorations for Buffets.

The decoration of the buffet or sideboard forms an important point in the floral arrangements of the dining-room, and one not to be overlooked, though such is too often the case. Across the back of the sideboard nothing looks better than a handsome arch, formed of flowers and foliage; cut sprays can either be employed for this purpose, the ends being inserted in wet

sand at each end of the sideboard, or growing plants, one at each end, may be substituted, the pots being either concealed by ornamental cases or Fern fronds. Common Ivy forms a good foundation, as do also sprays of Cobaea, through which flowering creepers may be twined. The latter must be selected according to the season of the year, but the former, I need hardly remark, are always obtainable. A large stand of cut flowers looks well placed in the centre, and if a silver epergne, so much the better; for, though I dislike silver stands for flowers on the dinner-table, they are by far the handsomest for the buffet, where too much silver can hardly be grieved, provided that flowers and foliage are associated with it in such a manner that one sets off the other to advantage. Flowers for stands on the sideboard should be large, and arranged with as bold an effect as possible. A rough block of ice, with Ferns and flowers round the base, a few stems of bloom inserted in the ice (little holes having been drilled for that purpose), and a few light sprays of *Lygodium scandens* lying over the whole, have a charming effect; but where this style of decoration is used, there must be some vessel employed, into which the water from the ice can drip. Well-grown Palms, Ferns, and flowering plants also look well, but neat small plants are the most effective, as, if large-sized, they tend to give the arrangement a heavy appearance.

A. HASSARD.

AQUATICS IN BOTTLES.

THE more we see and know of plants for room and window gardening the more apparent does it appear that we have yet much to learn. Ferns, succulent plants, dwarf half-hardy Palms, and even some of the cooler-growing tropical Orchids,

Pontederia crassipes in a Bottle.

have been repeatedly recommended for indoor culture in window-cases and rooms, and I now wish to point out the adaptability of aquatics for that purpose, many of which will grow in a bell-glass in open windows, while some of those commonly grown in plant-stoves will luxuriate in a Wardian case or under a close glass shade, and actually give less trouble to their owners than *Geraniums* and *Fuchsias*. Our illustration represents a plant of *Pontederia crassipes*, grown by Mr. Kennedy, in a common Hyacinth-glass filled with soft water. His establishment in Covent Garden is, indeed, full of curiosities in this way. This plant was one of several which had been grown in an open shady window along with plants of the common bright green water Lettuce (*Pistia stratiotes*), which also grow well similarly treated. One of the best of all aquatics, however, for window or sitting-room culture is the

smaller variety of *Aponogeton distachyon*, which grows vigorously planted in sandy loam placed at the bottom of an inverted bell-glass. Another favourite plant for indoor aquaria is *Vallisneria spiralis*, the bright green semi-translucent grassy foliage of which is very ornamental. Apart from exotics, we have an abundant store of native plants, which may be grown either in Hyacinth-glasses or in inverted bell-glasses; and many of our common water-weeds, such as *Chara*, *Potamogeton*, *Anacharis*, *Callitriche*, *Lemna*, or *Hydrocharis*, readily submit to this system of culture. In addition to plants, a few water-beetles or small gold-fish might be added, to give life and interest to such aquaria. The only attention which water-plants require is a fresh supply of rain or river-water every week, taking care, at the same time, to remove all dead or decaying matter, so as to keep the whole fresh and pure. All through the summer and autumn months many sub-aquatic plants, such as *Cyperus alternifolius* and its variegated variety, *Narcissus*, *Nerines*, and other bulbs, may be grown in Hyacinth-glasses with as little trouble as that which attends the culture of the most ordinary window-plants; or, if they are filled with wet *Sphagnum*, sprigs of *Spearmint* or sprays of *Wood Ivy* will root and grow as freely as if they were in their natural haunts.

B.

GARDENING AT SALT LAKE.

ON making a late trip to the Rocky Mountains, I certainly did think it very curious that at none of the mines or mining camps, nor at any of the houses of the owners or managers, or at the mines or farms that I visited, did I ever see any attempt made to form a flower garden—very rarely even an attempt at raising a few vegetables. At all the stations or settlements, or houses in mining camps that I saw, the houses were placed on the bare ground, without enclosure or attempt at neatness or consideration for amenity. Sometimes, indeed, you would see a sort of enclosure at the back, but this is for the cattle or waggons, and is devoted to their use, and almost invariably is put up in the most temporary and makeshift fashion. The only places where I saw gardens in Utah were in Salt Lake City. It was otherwise in California, where the usual evidences of longer civilisation showed themselves in most towns, even mining towns of any standing. But with the exception of Salt Lake City, all the towns in Utah are of comparatively recent date. In the accounts of that city we usually read of the beauty with which it bursts upon the eye, with fruit trees rising among the houses, and reminding one of an eastern city. I can only account for this style of (according to my view) exaggerated admiration, by supposing the writers to have been sojourning for some time, either on the treeless prairies of the east, or among the alkaline deserts in the west, and so to have had their minds disposed to see exceptional beauty in anything approaching to trees or foliage. To one not so prepared, it needs a strong imagination to be able to see in the small orchards of less than five-and-twenty years growth, the richness and beauty claimed for the city; for with the exception of a single cluster of larger Cotton-wood trees (*Populus monilifera*), around one of the older houses, and which probably were there before the arrival of the Mormons, all the trees, whether Cotton-wood or fruit trees, are young, and have been planted since the foundation of the city in 1848. When in the city itself, young as they are, the trees look tall, but when seen from a little distance, as from the hills at its back, they dwindle to their proper value. They do not overtop the buildings, and, in general, scarcely reach the house-tops. Looking down on the city from these hills, we see far to the south the wide valley stretching before us. Its aspect is desolation itself. The few cultivated farms beyond the city are all within three or four miles of it, and then nothing but an unbroken expanse of Sage meets the eye. It has nothing of the greenness of Grass, but a uniform brownish-olive colour, spread out without interruption, until it melts in the haze of some distant low hills. The lofty ranges on each side redeem the landscape from sameness, but cannot save it from dreariness or desolation. On this side no water is seen, for the Jordan, which flows down the middle of the valley, creeps along out of sight between muddy or sandy deposits, through which it has cut its way; and when

the eye looks for relief to the nearer city beneath, it turns away disappointed, for the buildings are generally placed wide apart, and being wholly built of wood, both walls and roofs have all a grey uniform tint, giving them, at some distance, the aspect of rectangular grey boulders dotted over the plain. The absence of chimneys strikes the European eye; they are not needed, for the heating and cooking is all done by stoves, whose chimney is a slender iron pipe sticking up out of the side or in the rear of the house. I had no previous idea how much the picturesque beauty of our landscape at home owes to our square massive chimneys and to our roofs being slate, thatch, tile, or something different in colour from the walls below them. On a closer inspection of the trees I found that the young Cottonwood trees which line some of the streets, are suffering badly from the attacks of a goat or leopard moth, which bores in and eats away the wood, exactly as our goat moth does. While I was there a tree close to the hotel in which I boarded was broken right across the middle, at a place greatly eaten away by these insects. I got some old cocoons, but saw no specimens of either the larva or the perfect moth, so cannot give it a name. Some of the trunks, much bored by them, which they had deserted, I found taken possession of and utilised by swarms of a small black bee. The fruit trees seem perfectly healthy; they were principally Peach trees and Apple trees, and their lavish flowers beautified the place immensely in spring. I did not happen to notice any of them attacked by insects, their position in private enclosures not being favourable to entomological examination; but I have no doubt they must suffer considerably from the attacks of an insect very similar to our lackey moth, for in the hills, a mile or so off, I found a wild *Prunus* which occurred in considerable abundance in the hollows on the hill sides (and which is probably the Chokeberry of the settlers, or *Prunus virginiana* of botanists), terribly infested by the caterpillar of such a moth. I found the necklaces of eggs surrounding the twigs exactly as with our own, only slightly smaller, and almost every bush disfigured by such a caterpillars' nest as the larva of the lackey moth spins, consisting of a thick white web, tying together a few twigs in and around which scores of caterpillars, very similar to those of the lackey moth, were busy at work, creeping out and creeping in. I brought home with me to my room, two or three of these nests, first carefully removing all the caterpillars that I could find, and for a week after I had to endure a succession of them, making their appearance and crawling over the walls and furniture, and not even holding my own person or that of my friends sacred, one of whom I had the mortification to see a good deal discomposed by the appearance of first one and then another upon his clothes during a short visit that he paid to me, but I did not feel called on to enlighten him as to the source whence they came. The Apples are said to be good—whether better than our own or not, I had no opportunity of judging, not even such a one as Hepworth Dixon tells of—"When I was leaving Salt Lake City," says he, "Sister Alice, the daughter of Brigham Young, put up some very fine Apples in a box for me to eat by the way. At a station on the plains, I found that a lady, a fellow-passenger in the waggon, had been opening my box and helping herself to the fruit; and when she saw me looking at her, with some surprise perhaps visible on my face, she merely said, 'I am trying whether your Apples are better than mine.'"

The Peaches I can vouch for being the worst that ever I met with; small (not much larger than a Walnut), yellow, fuzzy, juiceless, flavourless, bits of sponge. Until I tasted these, I never knew the meaning of the American boast, that on the settlers' farms the Peaches were so plentiful that they were given to the pigs. I am sure that in Utah they could not be put to a fitter use, provided only you can persuade the pigs to eat them.

Burton, in his "City of the Saints," records—that when he visited Utah in 1867, a Vineyard was then being planted on the hill-side near Mr. Young's block, and expresses his belief that "home-made wine will soon become an item of produce in Utah." I heard and saw nothing of this, although I know well a Sage-clothed brae behind Brigham Young's block that is well adapted for the experiment. I imagine it must have failed, because I was asked by Mr. Jennings, one of the most prosperous merchants in Utah, to advise him as to the health

of some Vines he had growing in a greenhouse in his garden. I found the Vines to be slender pany canes, with the leaves small and yellowish. Mr. Jennings was inclined to refer their unsatisfactory condition to potash and other alkalis in the soil. But one would think that the alkali had surely been sufficiently washed out of the soil in and around the city by this time to allow everything that suits the climate to grow freely. It is said the worst alkali lands will get rid of their superfluous alkali by five years' luviation, and here the ground has been subjected to five-and-twenty years' irrigation. I therefore, incline to think that we must look elsewhere for the cause of the failure of the Vines, and I am more disposed to charge it to the cold of the winter. Mr. Jennings's greenhouse was a common small span-roof structure of glass and wood, standing on the bare ground, without foundation or flues, and the roots of the Vines of course as much out as in the house. A few days previously the ground had been covered with snow, and, the cold during winter, without being very intense or uninterrupted, is nevertheless pretty sharp; and it may help the reader to judge of the severity of the winter, if I mention that Mr. Jennings had tried the Irish Yew, the Bay, the Portugal Laurel, the Holly, and various other common evergreens, but they had all died during the winter; and, although he intended to try Elms, Planes, and other old country trees, he greatly feared they would not live. Nor had he been more successful in introducing Pines from the neighbouring mountains, which he had tried to do by transplanting them; but, I would not despair of these, for I found some Douglas Firs and *Picea grandis* growing in the bottom of one of the neighbouring canons only 200 or 300 feet above the level of the plain, and, at any rate, it could not be the cold that hurt them—it might be want of care in transplanting. But having no pretensions to practical knowledge of Vine-growing, I should be glad if any of the able Vine-growers, who from time to time impart their knowledge to us through the pages of your journal, would say (so far as the information given allows) to what they would ascribe Mr. Jennings's want of success. I should add that he had a Scotch gardener, that is to say, a Scotch labourer, who, at some former period of his life, had picked up some knowledge of gardening, and who kept the rest of the garden, especially the vegetable part, in very fair order. Gooseberry bushes seemed to thrive well enough; which, perhaps, is not surprising, seeing that they grow wild in the Sierra Nevada, where Douglas found them. I found one in the Sierra Nevada in fruit in July; the berry small but very hairy, and the hairs very long and very stiff, almost as long, indeed, as the diameter of the berry.

I did not notice our Black, Red, and White Currants, although I have little doubt they were there; but the yellow-flowering Currant seemed a great favourite. Mr. Jennings's garden was surrounded by an excellent hedge of the Osage Orange, which was almost the only fence that could be called a hedge in all the City. The common Hawthorn will not grow there, the winter being too severe for it. I found the same thing even in Upper Canada. As to flowers, I saw nothing that is not common in England. In front of one or two of the best houses you might, in spring, see a few Hyacinths or Parrot Tulips planted out, and the usual common flowers, such as the purple Iris, Roses, &c. In Mr. Jennings's greenhouse were the usual Tom Thumb Geraniums, scarlet-flowered Pelargoniums, the variegated *Coleus*, and such like; but I do not think that anything interested me or affected me more than to see in a little patch, not 12 feet square, in front of a small house, a few plants of the variegated Balm that you commonly see in the cottage gardens in Scotland. I could have wagered that the residents were, or had been, "cotters" from the old country, as I could that those in the next plot were not, who had, in the hot days of July, removed their double cooking-stove out of the house into their little plot, where I saw it standing busily at work in the open air.

I cannot pretend to nominate all that I saw or missed; it would serve no good purpose, and the cursory notes that I have given should be enough to enlighten anyone, that is interested in the subject, as to the true character of the climate and the great, but as yet undeveloped, horticultural capacities of Utah.

ANDREW MURRAY.

THE FLOWER GARDEN.

STRELITZIA NICOLAI.

This plant is one of the most graceful members of the Musal alliance, and deserves to become popular in our gardens and conservatories as a striking and elegant decorative foliage plant. It is sufficiently hardy to withstand our climate during the summer months, and grows even more freely than most of the Musas when planted in a richly manured soil and in warm sheltered positions. In habit the plant is more robust than any of its congeners, if we except *S. angusta*, which frequently attains a height of from 30 to 40 feet, treated as a warm conservatory plant. Both the last-named plants are chiefly remarkable for their fine foliage, but some of the smaller-growing kinds, as *S. ovata* and the even more beautiful *S. reginæ*, are well-known flowering plants, generally grown in a warm conservatory or in a humid plant stove. These species will, however, both grow and flower well in warm sheltered positions out-of-doors, and form striking objects massed along with Musas, Palms, and the larger Arads. Our illustration gives an excellent idea of the noble port assumed by well-grown specimens of *Strelitzia Nicolai*, which, although common as a half-hardy foliage plant in many Continental gardens, is very rarely to be met with in this country. B.

NEW DOUBLE-FLOWERED ZONAL PELARGONIUMS.

SOME months since, those of your readers who were interested in the above class of decorative plants were much indebted to M. Jean Sisley for some very interesting information regarding the origin of these popular and really beautiful plants, and certainly no one could be found better qualified for the task he set himself, than M. Sisley, who has probably done more than any other cultivator towards the improvement of this useful family of plants, and was the first, and, I believe, as yet, the only raiser who has succeeded in producing a double white variety. The improvement which has been effected in this section of the Zonal Pelargonium during the last fifteen years, or since *Triomphe de Gergovia* was discovered in the Botanical Gardens of Clermont-Ferrand, Puy de Dôme, in France, is something very remarkable; and this would, no doubt, be readily admitted were it possible to compare some of the more recent introductions with the above-named variety. On seeing the first blooms of some of the very fine sorts which were introduced last year, the production of English as well as of Continental raisers, I felt inclined to think that the double-flowering Pelargoniums, like their tricolored-leaved congeners, had nearly, if not altogether arrived at their *ultima thule*, and that the march of improvement could proceed little, if any, further. But on flowering three of M. Sisley's latest productions, which M. Aléatière, of Lyon, is now distributing, I felt pleased to find what I,

at least, considered a very decided advance on all previous introductions; indeed, I think the variety named *François Pertusati* must certainly be considered amongst the most unique and beautiful of all the double sorts which have, as yet, been introduced. The habit of the plant appears to be very good; the foliage is slightly zoned, and it has the appearance of being a very free-blooming variety; but, as my plant is, as yet, small, I cannot, of course, speak with certainty as to this quality. The florets or individual blooms are large and loosely double, and appear to lose their entire individuality in the formation of a finely-shaped globular truss of immense size and of a richly-shaded salmon colour; the petals being long, become lighter in colour or nearly white towards the margins, which imparts to the well-formed truss a singularly

beautiful appearance. George Sand is also a very remarkable and distinct variety of dwarf and compact habit of growth, the foliage being of a light green shade of colour and slightly zoned. The individual flowers are exceedingly large, with long and somewhat irregular petals; forming, however, a finely-formed truss of large size. Under glass the flowers are almost pure white, but they assume in the open air, or even in a situation much exposed to the sun, a delicate rose-coloured tint, which renders the truss exceedingly beautiful. Carl Vogt is of a somewhat stronger habit of growth, with a well-defined zone upon dark green foliage. This is also a very striking and fine variety, the shade of colour being new and peculiar. P. GRIEVE.

Oxford, Bury St. Edmunds.

A noble *Strelitzia*.

THE FLOWER-WALK IN REGENT'S PARK.

THE ornamental part of the Regent's Park, so tastefully laid out a few years ago by the late Mr. M. Nesfield, consists of two parts—one, an Italian flower garden, placed on each side of the fine Horse Chestnut avenue; and the other, an open undulating space, laid out after the manner of an English pleasure ground, with serpentine walks and different-shaped clumps, containing selections of the finer kinds of flowering shrubs and evergreens. Of these, some of the more striking are also planted singly on the Grass, along with the original trees, which having now attained considerable size, form fine objects, and provide ample shade in summer. In the Italian garden are some handsome vases, judiciously placed, and which, when filled with Geraniums and other suitable plants, form striking objects. There are also a number of fine Yuccas, variegated Hollies, and other evergreen shrubs, planted singly on the Grass borders which surround the sunken beds in the central compartments. The flower-beds are edged with Box, the small walks gravelled, and the whole surrounded by an edging of Austin's stone, inside of which is a border of Ivy. Lombardy Poplars, supporting Grape Vines, which twine around their stems, are planted at regular distances on each side of the straight main walks. These, when regularly pruned, form a good substitute for the upright Cypress, which does not thrive about London. Some of the circular beds in this part, are filled with sub-tropical plants, and are now very effective. What is called the Colosseum ground was originally quite flat, and, owing to the crowded state of the trees, in many places destitute of

Grass. The undulations consist chiefly of material supplied by the Underground Railway, surfaced with the original soil. This garden is at present in full beauty. In the beds are Castor-oil plants, *Dracenas*, *Aralias*, *Arandos*, India Rubber plants, and the old-fashioned Hollyhock, whose fine form is desirable for the sake of variety. Nothing very delicate or tender is introduced. It was Mr. Nesfield's intention to have had, if possible, a fine entrance to the park from Portland Place, in a direct line with the broad walk; another wing added on the west side, similar to that on the east; and, on going northwards, three rows of Elms swept away to make room for a row of Limes, scarlet and white Chestnuts, and a few of the larger *Coniferae* planted on what might become a lawn, provided the idea was carried out.—I.

SEDUM SPECTABILE.

SEDUM SPECTABILE—*Fabaria* of some, and *rosenn* of others—is a most useful plant for flower-garden decoration. It flowers late in the season, when most of the summer-blooming plants are losing their lustre. Previous to its coming into flower, the glaucous foliage of this *Sedum* tends to give a pleasant relief to any high coloured plant which may be in conjunction with it. Its fine heads of rosy-purple flowers expand about the beginning of August, and it remains for two months, and sometimes longer, in stately perfection. Planted in lines in ribbon-borders, it is particularly effective when placed in centres of beds, or in patches by itself it also looks well. Like others of its class, it withstands extreme cold, heat, or wet, with impunity. I saw it in quantity a few days ago, with Mr. Knight, at Floors Castle, Kelso, where it has been extensively used for years with telling effect. I remember seeing it in magnificent order at Hampton Court, some years ago, when the gardens there were under the control of Mr. Donald, at which place it was principally planted under and around the large spreading dense Yew trees in the flower garden. In this situation, as in the unshaded beds, the fine heads of flower, some of them a foot across, were fully developed, high in colour, and perfect in every way. Not a great many plants will grow, and fewer still will flower, in such shaded places, and this *Sedum*, doing both to perfection, should secure general cultivation in like situations. It is often grown on rock-work or elevated mounds, but, as it grows from 1 to 2 feet high, it is best suited for the lower flats and cavities, where the whole plant can be seen to advantage. A rich soil suits this *Stonecrop* best, but it thrives in nearly any compost. The stock may be easily increased by dividing the old crowns. Unless where a change is desired, it is not necessary to remove it annually. Cultivated in pots for late summer or autumn decoration of the greenhouse, or wherever hardy plants in pots may be needed, this variety has no equal amongst *Sedums* or succulents generally. In an 8-inch pot it produces from six to twelve spikes, and these, when furnished with their large heads, form a collective mass of bloom 3 and 4 feet in circumference.

J. Muir.

Clifton, Gloucs.

Sweet Peas and their Culture.—The Sweet Pea has improved in common with many other popular flowers, and there is reason to believe it is capable of a greater improvement than it has yet received. The recent introduction of two large-flowering varieties, the Scarlet Invincible and the Black Invincible, both very fine, show that valuable selections are being made. One of the best known varieties is the Painted Lady; this has a pale rose standard, as the upper petal is termed, the wings (or side petals) and the keel being white. This is a very charming form, and it is a great favourite in our gardens. There is an improvement on this known as the New Painted Lady, in which the standard is of a deeper rose, and contrasts most effectively with the white wings. The Black Sweet Pea has a very dark purple standard, and deep rosy-red wings and keel. Then the Purple comes in the same way, but with a paler standard; the Purple Striped has the wings and keel striped with white. One of the handsomest is the Scarlet Invincible, a fine large variety, with the standard of a bright scarlet hue, and the wings of a clear rose. The Scarlet Sweet Pea is a smaller form of this, and the Scarlet Striped is the same, but prettily striped with white. The Blue-edged Sweet Pea is a form of the purple, with a margin of blue to the wings; but its character is scarcely fixed enough to be regarded as a permanent variety. The White Sweet Pea is wholly of this colour, and is very charming indeed where mixed with varieties of deeper tints. There are many ways in which the Sweet Pea can be turned to account in the adornment of a garden. A common method is to sow little patches in borders, the seed being generally that of mixed varieties, and then, by placing some stakes against them, secure pillars of flower. When it can be done, a hedge

of Sweet Peas is an attractive sight, and sometimes it can be turned to account to hide an unsightly place during the summer. Many gardeners grow a hedge in this way in order to yield a supply of cut flowers, which it always does in plenty. I once saw a charming combination at Muckross, Killarney, the seat of the Hon. Capt. Herbert, M.P. Across a portion of the kitchen-garden were several hedges, made of the bright-coloured Scarlet Invincible Sweet Pea, and *Tropaeolum canariense*, mingled together. In the soft moist climate of Killarney there was a profuse growth and an abundant bloom, the flowers of both being very fine. It is useless to grow the Sweet Pea unless planted in good soil. Many gardeners sow in pots in the autumn or early spring, and place them under glass, so as to bring the plants in flower early in summer.—R. D.

Flowers on Lawns.—We could do much better with a portion of our lawns than continually shaving them. Numbers of pretty Alpine and bulbous plants thrive freely and flower abundantly in short Grass, even if occasionally mown. There is a little lawn at Worthing now dotted with the flowers of the Harebell. It seems to have been mown several times during the season; but the Harebells have come up again, the delicate blue bells being on stems 3 inches high instead of the usual height of the plant. Such a very attractive system is not in keeping on the more frequented parts of the lawn; but there is in many gardens a good deal of mown surface which would look much better if adorned with such jewellery of plant life.—R. W.

The New Rockery at Kew.—This, notwithstanding what has been said against it, is now looking better than any rockery I have seen this season, and, though I am afraid a good many of the plants on it will hardly stand a severe winter without protection, it has been a great success at present. Among the rarest and most interesting plants I noticed on it, most of which are now in flower, were:—*Spraguea umbellata*, *Saxifraga Stracheyi*, *Polygonum Brunonis*, *P. capitatum*, *Dianthus libanensis*, *D. saxicola*, *Mazus bellidifolius*, *Hebenstreitia dentata*, *Astragalus sericeo-albus*, *Micromeria piperella*, *Lobelia littoralis*, *Stobea purpurea*, *Corethogyne spathulata*, *Anchusa capensis*, *Stachys corsica*, *Eustachys distichifolia*, and the finest plant of *Omphalodes Lucilae* I have ever seen. Several of the half-hardy Begonias, as *Sedeni*, *intermedia*, &c., were flowering freely at the same time. In the herbaceous ground I particularly noticed a very fine *Datura* (*D. meteloides*) in flower; also, *Aquilegia chrysantha*, a splendid plant; *Nigella Fontanesiana*, and *Didiscus cæruleus*.—H. J. ELWES.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Lilies in 1874.—I think the past dry season has been peculiarly well suited for *Liliums*. *L. excelsum* has bloomed strongly here, the stems being more than 6 feet high. I think I never before saw that glorious old plant, *Lilium candidum*, so fine as it has been this season. Lilies are the easiest to grow and among the noblest of flowers. We shall, I believe, soon see them again in every garden.—J. W.

Gaura Lindheimeri.—This graceful plant is now blooming beautifully here. It has attained the height of 4 feet, and when its slender branches are moved by a gentle breeze, the beautiful white blossoms, seen at a distance, appear like so many butterflies dancing in the air. It is not quite hardy in this cold damp locality. It is best raised from cuttings in autumn, which may be kept in a cold frame through the winter and planted out in May; rich loamy soil suits it well.—J. WHITTAKER, *Mortley, Derby*.

Wintering the Spring Navel-wort (*Umbilicus spinosus*).—The striking resemblance this plant has to the hardy *Sempervivum* is likely to lead anyone, who may have procured it through the summer, to suppose it is hardy, and treat it accordingly. It should, however, have the same protection and treatment during the winter as *Echeverias*. We lost a very fine lot of it through its being inadvertently left out in the cold last winter, and I write this that others may not go and do likewise.—J. Muir.

Hardy Plants for a Dry Soil.—I shall be greatly obliged by your informing me of some hardy plants suited for a very dry and rather poor soil.—SER. [The following plants will be found to succeed:—*Artemisia* in variety, *Statice* in variety, *Vinea major* and *minor* in variety, *Pyrethrum*, *Tetradlea*, *Artemisia nobilis plena*, *Alyssum saxatile*, *Andris alba*, *Antirrhinum majus*, *Wallflowers*, *Centranthus ruber*, *Cerastium* in variety, *Pinks* and *Carnations*, *Campanula variegata*, *Lysimachia nummularia*, *Rudbeckia hirta*, *Sedum*, *Asters*, *Gypsophila paniculata*, *Saxifraga* in great variety, *Sedum*, *Sempervivum*, *Thymus* in variety, and *Corydalis lutea*. Pea-flowered plants generally thrive well in dry soils, so do many of the Composite.—ED.]

Wilderness Roses.—For this idea, says Mr. Rivers in his "Amateur's Guide," I am indebted to Professor Owen, who, wishing to ornament a wild part of his ground full of Thorns, Grass, and weeds, adopted the following plan, which, I am inclined to think, is quite worthy of record. Large sewer-tubes, rejected on account of flaws in the enamel lining, were sunk vertically in the pure gravelly soil to within an inch or so of the surface, and filled in with loam and manure, and a Rose planted in the centre of each. The soil in the tube was kept free from weeds, and the running Grass and other weeds outside were prevented making their way into such good quarters. To give the Roses extra vigour, some manure-water was given to them occasionally in the summer. The effect of Roses growing in the highest state of luxuriance in a wilderness was most charming. The inside diameter of these tubes is 16 inches, their length 30 inches, so that they go below the roots of weeds, which would otherwise soon devour the rich compost in which the Roses delight.

THE SHAKESPEAREAN GARDEN.

MANY of the allusions made by Shakespeare to plants and their products, involve or seem to acknowledge the superstitions and credulities of former ages, especially as recorded in books. He tells us that Fern-seed has the power of rendering a person invisible; that the use of Rosemary quickens the memory; that the sudden perishing of the Bay-tree is ominous of evil; that the use of Fennel improves the sight, and that when "torn out of the earth" the root of the Mandrake "shrieks," with results so terrible to the bystanders—

That living mortals, hearing it, go mad.

Shakespeare, of course, never believed these things; he knew the difference, as well as any man, and better by far than thousands of men, between fact and fiction; he simply accepted the superstitions and the folk-lore that were current in his day, for what they might be worth, and left it to his readers to separate the veritable from the fabulous. So doing, he paid them the most graceful compliment that an author can render, which is to assume that his reader is sufficiently intelligent to distinguish at all times between the mythic and the genuine, and so well read in the literature of all past ages that he will recognise every allusion, and never need to be told which is legend and which is history. A man of liberal education and well cultivated taste is at once differentiated from the vulgar and the uninformed by the ease with which he separates the poetical ornament from the prosaic warp and woof. Shakespeare, more perhaps than any other man who ever lived, quickens our powers and aptitudes for so doing; not by precept, but by that sweet magic of secret influence which always sinks so much deeper than didactics; hence he becomes our tutor, though we may not think it as we go along, in everything that makes intellect strong and beautiful. Where Shakespeare got all his information is a mystery. Of the extent and qualities of his education, conventionally so called, we have no exact and minute records. It may reasonably be doubted if he was ever diligent at lessons. It is pleasanter, in truth, to think of him as a man who, from his youth upwards, stood away and apart from mere book knowledge, since we then become more impressed with his originality. That which in Shakespeare was pre-eminently remarkable, and which stood with him in place of what in modern days is called "information," or "a good education" was *insight*, the superb faculty by means of which the mental vision instantaneously co-ordinates itself with the breadth and altitude of things, the least as well as the greatest, and which, at the same time probes, without effort, to the innermost centre. Shakespeare had the felicitous power, most especially, of seeing things, not only as to their outsides, as most people are fain to content themselves with doing, thereby falling every day of their lives, into the most ridiculous and unfortunate mistakes, but as to their inmost substance and kernel. Whatever he looked at, he saw *through* it. With a man who can do this, book-learning, despite its value to the mass of mankind, is intrinsically of slight importance. There is little need, therefore, to inquire who were his schoolmasters, or what was the range of his reading as a student by the "midnight oil." It would be interesting could we know authentically what books he was accustomed to resort to for his chief pastime in reading, when a lad; but I question if it would throw much, or any, light upon the source of the grandeur of his utterances. Shakespeare was the representative of Power, rather than of knowledge, taking the latter in its accustomed arbitrary and technical sense of a heap of facts which too often—

Like Saul's plate-armour on the shepherd boy,

serves less to arm than to encumber. He discerned the fundamental and essential beauty of things, as it exists independently, of what man may do, or fancy he may do, to render it trim and tidy, penetrating through the apparel imposed by art, to the glorious first principles that endure unchanged for ever. How accurate his perception of what constitutes a garden! How charming the sentiment that pictures the "Woodbine coverture"; the quick eye for

The Marigold, that goes to bed with the sun,
And with him rises weeping.

And how exact his ideas of the rule, the design and result of many a little detail of the gardener's art, that one would fancy belonged only to the professional. Take, for example, the reference to grafting:—

You see, sweet maid, we many
A gentler scion to the wildest stock;
And make conceive a bark of baser kind
By bud of nobler race. This is an art
Which does mend Nature: change it rather; but
The art itself is Nature.

I doubt if many of our current horticulturists, except those who are readers of Shakespeare, recognise so perfectly in the work of their hands (the admirable practical work which helps to render our island so fair and fruitful), that when pure and noble art is wisely applied, instead of interfering with Nature, or superseding it, the act is really one of ministration to Nature. The gardeners, more than any other men, are the trustees of living Nature; it is theirs, not only to protect it, to eat of it, and to supply the market-place with what it yields in the form of flowers and fruit, so that money shall flow to their pockets, all of which is extremely proper, and exemplary, and laudable; it is theirs, at the same time, so to cherish and foster it that the world shall wax more lovely through their work. Magnificent, no doubt, are the uses to the world subserved by manufacturing, by commerce, and by literature; but the beauty of the earth, as regards its cultured vegetation, is to civilised mankind every bit as important. Beauty is quite as large a fact as utility; it is the happy function of the gardeners to sustain it; no man should presume to call himself a gardener who does not feel in his inmost heart a deep and reverent love of beauty, and that he is an enthusiast for life in its behalf.

That Shakespeare's acquaintance with individual species of trees and plants, in the strict botanical sense, was scanty and casual, is likely enough. He had no occasion to possess the minute knowledge that we expect in the curator of a botanic garden. Sufficient for us is it that his piercing eye saw in many a little flower what had never been detected by anyone else. I do not dispute the desirableness of knowing that the *Campanula rotundifolia* is distinguished by having the "lobes of the corolla considerably shorter than the tube," as taught in the floras; but it seems to me quite as pleasant to be able to see without instruction, as Shakespeare did, that this darling of the ripened summer, the little Harebell, is "azure," and not simply blue, as a hundred other flowers are. Of the two features in question, for my own part I think I would rather see, as the better, the one that Shakespeare saw; and similarly, at another season, that although the Daffodil is differentiated by its "elongated crown," it comes, not merely in spring, but "before the swallow dares." Bare facts, such as Shakespeare never rested in, are but like "the letter which killeth," *i.e.*, serves the intellect without ever touching the heart; contrariwise, the "spirit which giveth life," is found, as regards temporal things, in the faculty, which, like the stream in the "Two Gentlemen of Verona," not only "makes sweet music with the enamelled stones," but giveth

A gentle kiss to every Sedge,
He overtaketh in his pilgrimage.

A proper question at this point, as a first step in the study of the Shakespearean garden, is what books the great dramatist may probably or possibly have been indebted to—directly or indirectly—for the quaint credulities and superstitions above indicated.

Books on Plants in Shakespeare's day.

Fanciful properties existing in plants formed a considerable portion of the herb-craft of the time; and, though amusing enough in our own enlightened age, from their very absurdity appear to have been implicitly believed in by the mass of the people. Let us not forget that out of many of them have arisen the facts of the pharmacy of to-day. Falsehood there is in the world, and in abundance, no doubt, but there is not so much falsehood as misconception and misunderstanding. We may gather plentifully, from his own utterances, that, though in a certain sense independent of books, he was by no means unacquainted with them. A man

insensible to the value of books could never have peened those noble words—

My library
Is dukedom large enough.

So far from it, they could only have come from one who understood to the very core that, next to Nature, good books are our truest and most precious companions. "When I come into my library," said Heinsius, "in the very lap of eternity, amidst so many divine souls, I take my seat with so lofty a spirit and such sweet content, that I pity all those great and rich, who know not this happiness." "These friends of mine," writes Petrarch, "regard the pleasures of the world as the supreme good; they are ignorant of my resources. I have friends whose society is delightful to me; persons of all countries and all ages, distinguished in war, in council, and in letters. Easy to live with, always at my command, they come at my call, and return when I desire them; they are never out of humour, and they answer all my questions with readiness. Some present before me, in review, the events of past ages; others reveal to me the secrets of Nature; these teach me how to live, and those how to die; these dispel my melancholy by their mirth, and amuse me by their sallies of wit; and some there are who prepare my soul to suffer everything, to desire nothing, and to become thoroughly acquainted with itself. As a reward of such services they require only a corner of my little house, where they may be safely sheltered from the depredations of their enemies." By the time of Shakespeare books were much more numerous than in the days of Petrarch, who died exactly 100 years before the former was born. Printing, moreover, was not invented for nearly a century after Petrarch breathed his last. Shakespeare stepped into a period when the truth of the immortal words just quoted was possible at least to every gentleman. When we ask what books he had, in other words, what was the composition of his library, of course it does not imply that Shakespeare held one of his very own, a private possession, bought or inherited, and contained within his house. His library is to be thought of in the same sense as the public or semi-private collections of books accessible to men of culture in this existing nineteenth century, and which are virtually the property of everyone who uses and appreciates them. Men should remember at all times, when reckoning up their wealth or estimating the value and the area of their possessions, that, by the munificence of God, we are all of us far richer in regard to what is usually omitted from the catalogue, than what we may have legal control over. The best property is that to which no individual holds, or ever can hold, the title-deeds. I count it equivalent to a thousand a-year, to possess, as my own, originally and inalienably, the sunshine, the fresh breeze upon the mountains, the sea, the trees, the wild flowers, and the sweet spectacle of the green fields. I count it equivalent to another fortune that I have the command of all the books in the British Museum. They would embarrass me, were they mine to sell and to keep in order; being mine to use, for solace and aliment, whenever I please, I am finally happy and content; yea, I feel myself as rich as the ancient Ptolemies of Alexandria.

Shakespeare, in this broad, and though external, thoroughly satisfying sense of ownership, had an enormous library. He was born, be it remembered, in 1564, and lived till 1616. All the great authors of ancient Greece and Rome were his—Sophocles the pathetic, Horace the polished, Lucretius the philosophical. The Phædon of Plato, the Poetics of Aristotle, Cicero upon "Friendship" and "Old Age," the picturesque histories of Xenophon, entertaining Lucian, lively and romantic Ovid, were all at command. Virgil had been printed as early as 1469, and for those who could not read Homer in the original, by 1603 came the translation of the Iliad, by glorious old Chapman. Of the ancient writers upon plants and the *Materia Medica*, Theophrastus had been printed in 1495, and four years later Dioscorides, both by the celebrated Aldus. Of the polite literature of the two or three centuries preceding his own era, there had come from Italy, besides Petrarch, the tales of Boccaccio, the poems of Dante, who died in 1321; of Ariosto, who died in 1533, and of Tasso, who lived into his own time, viz., till 1595. Cornaro, author of the

most amusing little volume ever compiled upon the "Art of Prolonging Life," died in 1566. From France had been contributed the fun of Rabelais (ob. 1553), and in 1580, appeared the far-reaching and sprightly essays of Montaigne. Brantome, the very man to attract a dramatist, was outlived by Shakespeare only two years; and it was upon the very same day that Shakespeare closed his eyes that the most illustrious of Spanish writers, Cervantes, author of "Don Quixote," also expired. England had reason already to be proud of her Chaucer; in Shakespeare's own time lived the author of the "Faerie Queene," Samuel Daniel also, who survived him three years, and the chivalrous and ill-fated Sir Walter Raleigh, author of that noble book, "The History of the World." To the English prose of this period belong likewise the writings of Lord Bacon, and of many another it is needless to specify. Enough has been mentioned to show that in the time of Shakespeare, the world already possessed some of the best books that give value to our own shelves. That Shakespeare had read them, or consulted them, or even a title of the number, of course, is not implied. Probably, he knew very little about any of them, except by hearsay; nor is it probable that he had read much even of the curious herbals which relate the superstitions respecting Fern seed, &c. The argument is simply that, in the old writings upon plants, we find the tales and fables, which, creeping into the folk-lore of his time, he introduces so felicitously when occasion invites. The earliest of these old herbals appears to have been the curious volume compiled about 1360, by Bartholomew Glanville, an English Minorite or Franciscan, of the family of the Earls of Suffolk, and who appears to have been the Pliny of his time. The book, which was called "*Bartholomæus de Proprietatibus Rerum*," deals not only with plants, but like Pliny's great Cyclopædia, with Nature in general. In 1398, an English version was made by a celebrated Cornishman, John Trevisa, included by Fuller in his "Worthies of England," and who, at the time of his work, resided at Berkley, in Gloucestershire. It was printed in London by Wynkyn de Worde, and a second edition was issued in 1535, or twenty-nine years before the birth of Shakespeare. Abroad it was several times reprinted, not only in the original Latin, but translated into French, Dutch, and Spanish. In some degree contemporary with it was the famous *Ortus*, or *Hortus Sanitatis*, the German version of which appeared in 1488. The "*Historia Plantarum*" of Fuchsius, with its hundreds of facetiously accurate and beautifully engraved drawings, was published in 1542, and was followed by the writings of Gesner, obit 1565; Matthioli, ob. 1577; Cæsalpinus, ob. 1603; Clusius, ob. 1609; Lobel, ob. 1616; the two Bauhins, Dodonæus, and several others well known to the archaeology of botany. The "*Historia Stirpium*" of the last-named was translated into English by Henry Lyte, who died 1607, the same year as the celebrated John Gerard, constructor of the well-known massive folio, and owner of the thrice-famous garden in Holborn. The date of the catalogue of this garden, 1596, is the one so often quoted as the year of the introduction into England of various exotics, no doubt brought over, some of them, long before, but of which this is the earliest mention. Wm. Turner, Dean of Wells, published his "Herbal" at twice, viz., in 1551 and 1562. Lord Bacon's "*Sylva Sylvarum*" should not be forgotten: a dozen other works, of more or less inferior note, might also be named. Pliny was translated into English by Philemon Holland, who was thirty-five when Shakespeare, at twenty-two, removed from Stratford-upon-Avon to the metropolis.

Such, accordingly, was the literature which Shakespeare had at command. Many things in his dramas are plainly illustrated in it; the best part of Shakespeare, nevertheless, is that which earlier authors do *not* illustrate, nor even anticipate. His influence upon our hearts comes not of what he had studied and learned, but of the richness of his insight. He was not a professed botanist, nor even an amateur florist, but we can always accept, unhesitatingly, whatever he has to say about simple Nature.

G.

Scions and cuttings of fruit trees have been worked with success nine months after being severed from the parent stock.

WATER.

IN natural landscapes, grand and peaceful expanses of water are always highly beautiful. Even on the reduced scale of garden landscape it is almost always attractive, and even an essential feature, where there is sufficient space to develop it fittingly. But where beauty is the object in small gardens, we must not meddle with water-features, which, if to be well carried out, require sufficient space. We must have no muddy duck ponds; no mere frog pits. Where it is attempted to introduce water as a feature in garden landscape, there must be ample room for the lakelet; otherwise, it becomes a mere caricature. A hole full of water covered

from every important point, sufficiently distant for a slight blue veil of intervening ether to "lend enchantment to the view;" or the distance must, at all events, be such as a man could not easily jump across, or else the so-called piece of water becomes a mere pond or ditch, and should be relegated to the poultry-yard as the muddy paradise of the water-fowl. It is not only for the sake of securing breadth and beauty in the water itself that makes it desirable to avoid artificial water in small gardens. A better reason is that water in such places must necessarily be brought much nearer the house than it ought to be. A filthy and formal piece of water is bad enough anywhere in a country place, but

A Piece of Artificial Water.

either with Duckweed, or any other surface growth that so soon covers any small space of stagnant water, is in that state not beautiful—but the reverse. How many otherwise pretty places, all over the country, are spoiled by the attempts to introduce the effect of water when there is not sufficient space for anything of the kind? A natural rivulet meandering through the grounds, be it only a mere thread of silver, is always a valuable addition, even in gardens of the most limited extent; but to attempt the effect of sparkle and repose, which is obtainable by the means of a sheet of clear water, is utterly futile unless the area at disposal be amply sufficient for its fitting display, and for sufficient breadth of water to enable the designer to make the opposite shore, as seen

it is unendurably hideous when fully seen from the windows. In Warwickshire and many other parts of England we have frequently seen wretchedly formal ponds within a few perches of the house. Frequently, to place these ponds in such objectionable positions, they are bolstered up on levels where water would not naturally lie; and, perhaps, when standing near them, one may see on the other side the tops of trees growing in the hollow where the water ought to have been—that is, if it were wanted at all. Very little consideration will suffice to point out that water should occupy what appears to be the lowest position, or, in other words, appear to be, as far as possible, in a valley. It need hardly be said that sanitary, as well as artistic, reasons point to the

necessity for not placing water too near the house. An indispensable point in the disposition of artificial water is, that its terminations should be concealed. Many natural pieces of water would look poor indeed if their whole surface were as plainly visible to the eye as a basin, and unbroken by projecting hills, trees, or the windings of the water itself. In the case of the pieces of artificial water we have alluded to, the margin is frequently as clearly defined as that of a fountain basin. It is quite easy, in forming a piece of artificial water, to conceal the terminations by planting, or by the placing small islands, so as to give it a very natural expression, and even to apparently add much to its real extent. In many cases, where the designer has neglected to veil the termination of the water so far as its plan is concerned, much may be done by judicious planting; but this should never interfere with the best aspects of the water, as it may be seen from the most frequented points of view, and much of the ground near a piece of artificial water should be devoted to gently-graded turf. The violent railway-embankment-like slopes, so commonly seen where the landscape gardener has been at work, are hateful. The pretty sheet of water devised in the accompanying illustration is not intended, necessarily, to exceed an acre; but, by concealing its real boundaries by means of promontories or islands, its extent has been made to appear much greater. From every important point of view a turn or slope should be made to appear as a channel leading on to other portions of the lakelet: though, in fact, its absolute termination is only concealed behind a promontory. The points of view from which the greatest apparent extent of the water is visible may be forced upon the spectator by the direction and nature of the approaches—as shown in the present design—while those points from which its real termination would be visible, must be rendered inaccessible by plantations and other natural devices. If the apparent cause of the lake or lakelet can be made to appear as a streamlet pouring down in a series of small cascades, as in our illustration, so much the better, as the general illusion of Nature in the midst of art, is thus rendered more complete. Finally, the banks and beaches must be naturally designed; there must be no regular or rigid outline, and the banks must occasionally sink into low gravelly beaches, losing themselves in the water, and in other places they may rise as high as the situation will admit. These heights must be clothed with brushwood and shrubs, and in one or two places, but not more, a weeping tree may be planted, not omitting a Kilmarnock Willow. Reeds must be very sparsely introduced into the shallows, as they spread rapidly, and even Water Lilies, so beautiful when only one or two groups appear, must not be used too freely. Water Lilies, the white and yellow, if too profusely planted, and not sedulously kept down, will sometimes entirely choke up a sheet of water in a very short time, and make its surface as green as a meadow. H. N. H.

Peach Kernels Poisonous.—It is not generally known, as it ought to be in gardens, that the kernels of some stone fruits, especially Peaches, contain prussic acid to an extent which may prove poisonous if a large number of the kernels be eaten. The following case, reported in the last number of the *Australian Medical Journal*, by Dr. W. R. G. Samuels, of Wanganui, New Zealand, should make parents cautious:—"I was sent for to attend a little boy, aged five years, the son of a carpenter of this town. On my way I was informed that the little fellow had eaten something unknown to his parents, and was believed to have been poisoned. On my arrival, I found him lying on the sofa in a state of partial coma. The pupils were dilated, the skin somewhat cold and clammy, the pulse feeble. He seemed, in short, to be suffering from the effects of some narcotic poison. Upon making inquiries, I was informed that about half an hour previous to my arrival he had been seized with dizziness, stupor, fainting, inability to stand without assistance—in fact, it was described to me as partial intoxication. He vomited 1 oz. or more of masticated Peach kernels. I at once administered an emetic, followed shortly by a full dose of castor oil, which soon acted on the bowels. I ordered him to be kept warm. After being placed in bed, he slept for about two hours, after which he awoke and seemed recovered. This was obviously a case of poisoning by hydrocyanic acid (prussic acid) contained in the Peach kernels, of which the child had eaten a large quantity."

THE FRUIT GARDEN.

FINE CROPS FROM YOUNG VINES.

THE way in which Vines are cropped is an important matter, as regards successful cultivation; over cropping is a great evil, and under cropping is equally injudicious. If over cropped, although free from insects, the bunches will be found to be deficient in colour and size, and comparatively destitute of flavour; shanking, which yearly destroys so many Grapes, is often attributed to imperfect root-action, but I am persuaded that in many cases it is induced by over cropping. Some varieties suffer more from over cropping than others, a remark especially applicable to Muscats of all kinds, while a much heavier crop than any of the Muscats could finish, is found to suit the Golden Champion, and other large-berried sorts, as in that case the excessive flow of sap is absorbed and the berries prevented from cracking. Under cropping is wasteful, as in that case the strength of the Vine is wrongly directed, and the crop is deficient. To allow only six bunches to remain on a Vine when twelve equally good ones might have been obtained, betrays bad management. I have frequently heard of, and sometimes seen, light crops sanctioned for exhibition purposes, but the best prize Grapes I ever saw were cut from Vines that were bearing a full crop. No very correct standard can be set up as to what constitutes a proper crop; according to some, a bunch to every alternate shoot should be allowed; this, however, depends on the size of the bunches; others recommend a certain weight for every square foot of glass; but what I consider the best guide is the strength of the Vines. Some Vines would produce forty pounds of Grapes with ease, while others of the same dimensions and age would fail to finish off properly twenty pounds. The capabilities of the Vine, therefore, whether great or small, should always be taken into consideration. This is the best of all tests, and one which, when applied with discretion, never fails to prove correct. Not a great many years ago, few Vines were allowed to bear fruit until they were three or more years old, and a full crop was not considered obtainable from them till they were more than double that age. Vine growers of the present day, however, find no difficulty in getting a full crop from Vines the third and fourth year after they have been struck from eyes, or in other words, Vines now-a-days, are allowed to bear full crops at an age when formerly they were not allowed to produce a single bunch. I have never known any premature failure or untimely end to result from early cropping. Indeed, I have seen better Grapes cut from Vines three years old, and which were continued to be produced for successive years, than ever I have known to be taken from Vines which were denuded of their fruit, under the impression that that operation would have the effect of husbanding their energies until they were six or seven years old. A Vine thus treated may make stronger wood than it otherwise would do, but strong wood is by no means the most fruitful or lasting. The best crops of Grapes I ever recollect having seen, were in two houses at Drumlanrig, in 1872. These were on Vines struck and planted in 1870, and when I saw them they were not only bearing, but had superbly-finished, eight, ten, and twelve great clusters each. Unfortunately, these fine Vines, as has been stated in your columns, were destroyed by Phylloxera, but they were immediately replaced by young ones in 1873, and this season the latter are bearing crops equal to those on many four-year old Vines. When I first saw the Vines at Tweed Vineyard they were two years old, and were bearing eight and ten bunches each, and anyone who saw these Vines then, or may have seen them since, will have little apprehension of untimely failure. The Grapes with which Mr. Hunter, of Lambton Castle, obtained the first prize at the great International fruit show in Glasgow in 1872, were cut from Vines raised from eyes in 1869; and Grapes from the same Vines carried off all the leading prizes at the grand International show in Manchester in 1873. I saw the Vines soon afterwards, and the crop was abundant and excellent. The Black Hamburgh Vine, from which the 13 pound bunch was cut, had seven clusters hanging on it, none of which were under 4 pounds, and some nearly as large as the "big one." These cases do not relate to extraneous produce, but to that of permanent Vines, which will continue to perfect fine crops for years. Still, notwithstanding the advantage of

such management, early and full cropping is not carried out as it should or might be. Judging from what I read in a contemporary, six and seven bunches, on Vines struck from eyes in 1870 (nearly five years ago), is considered an exemplary crop in some quarters. If Vines are at all what they should be at that age, they are capable of bearing far more than that amount with impunity, especially such sorts as Golden Champion, Trebbiano, Lady Downes, and Black Alicante. Borders have always an intimate connection with the production of good, bad, and indifferent Grapes, and success in the cases just cited, are attributed to the borders. These were made in the simplest possible manner with turf, to which was added one handful of bones to the cartload. J. H. M.

STONE FRUITS AND HARD SOIL.

It has often occurred to me, while observing the fruit trees growing on the walls of houses in many of the villages throughout England, especially in the southern districts, that the firmness of the soil has much to do with the longevity, hardiness, and fruitfulness of these trees, which are generally loaded with fruit of very fair quality. There is little attention given in the way of cultivation; all the training they get is a cut here and there to prevent the young branches from pulling the old ones from their fastening. They must have grown apace at some period, as large breadths of mason-work are covered with single trees, such as are not met with in many gardens. In this locality (Oxford) Apricots have been famous for many years, and great crops have been gathered; and the industrious villagers have often been able to pay their rents from the old trees on the ends of their houses. It has appeared to me in most cases that these veterans have been planted with very little care—probably a hole had been made large enough to twist the roots into, and the soil replaced over them, and rammed down as if to form part of a floor. The hard-trodden gravel (in many cases causeway and pavement), would lead one to suppose that moisture could never reach the fibres, but I suppose the fibres must travel to the moisture; a wide street is generally the space where the border should be. Other trees have the usual outhouses standing over the space where the roots are supposed to find their food. It is evident there must be food, or where is such fine foliage and luscious fruit manufactured? Vines are met with often growing under the same circumstances; one on a tradesman's house in a town not far from here, is something wonderful in its way—the kind is the black Esperione. I am told that it has produced heavy crops for many years past, and this year the bunches almost touch one another. There are only a few inches of open space between the pavement and base of the house front wall. The pavement and causeway together, between the Vine and the street, may be 12 feet wide, yet this Vine luxuriates, and supplies its owner with plenty of fruit, which is used generally for wine-making. Without discussing the matter further, is there anything we can learn from these trees, which are more productive, of stronger constitution, and less liable to disease than the finest-trained trees under the care of some of our most distinguished gardeners? From experience, I believe that the firmness of the soil prevents over-luxuriant growth, inducing the roots to become a mass of healthy fibre, instead of their sending out large soft feeders, drawing up large quantities of water, which remains in the branches till the short dark days of winter. No fruit-buds are matured; the buds start early into growth long before they are safe from frost; the sap, which has been flowing freely, receives a check; nothing is seen at the time, but before summer has advanced very far, a large limb (perhaps the healthiest-looking in the tree), dies off suddenly; it is cut out, other branches die off in the same way, and the poor tree is sadly deformed. Cases similar to this are met with all over the country, and yet we have found no preventive.

One thing I would suggest to young planters—that is, never accept a tree which has been often cut back in the nursery, or one which has not been properly cut. When pieces have been left, the branches are always liable to die back where these pieces have been attached. When the cut is clean and

properly done, the bark will grow over, and the wound will heal up nicely. When planting is done, never use manure (except for mulching, to keep out frost or drought); let all the soil, after it has been prepared, be made as firm as a rammer can make it—if stones are plentiful, so much the better; the soil may be placed over the roots, and made only moderately firm. Endeavour to get the tree to start freely, and use the knife only where it cannot be avoided. When the roots have run a little, they will come in contact with the hard-rammed soil, and will throw out fibre in all directions, which will cause the tree to grow sturdy, and the young wood will become very hard. When any shoot takes the lead, and is likely to monopolise the whole growth, take off a joint or two at the top, and a number of small shoots will spring up; train them over the empty space, and the foundation of a sound tree will be formed. Avoid the use of the knife in winter, if possible, and, if root-pruning should become necessary, let it be done early in the autumn; but examine the roots first at one side, taking off none except they may be going downwards, or away from heat and air; replace the soil, or fresh loam instead, ram it as hard as possible under the roots, lay every fibre carefully in its place, and cover them over as before. A very small portion of the tree thus treated will be enough to check unnecessary growth, and large firm leaves, plenty of natural fruit-spurs, and a hardy tree, will be the reward. The cutting round the whole tree with a spade, as some have done, is reckless and mischievous in the extreme. If too rich soil should be the cause of watery growth, lift the tree and mix some lime rubbish in the earth; ram it down, lay out the roots over it, and place 6 inches of loam over them. This should be done in autumn, when the leaves are about to fall. We should never despise the lessons which old trees in cottagers' gardens teach us, but search out the cause of their success, and it will be found that the roots are in their natural element; and the roots of our own trees, which are growing at railway speed, are in unusually rich quarters, where they will luxuriate till they bring about their own destruction.—*Gardener.*

Fruit Crops in Roscommon.—Apples here are a very heavy crop, especially Hawthornden, Devonshire Quarrenden, Juneating, Ribston Pippin, Kerry Pippin, Lemon Pippin, and King of the Pippins; Pears are a light crop, as are also Plums, Damsons, Cherries, and Filberts; Peaches, Nectarines, and Apricots are not grown outside here, with the exception of one tree of the Moorpark Apricot in a very warm sheltered spot, and that is bearing a full crop; Raspberries are always good here—this year the second gathering was larger than the first; of Strawberries, some sorts were very fine, and a heavy crop, more especially Eclipse, President, British Queen, and Wizard of the North. From the latter I am now gathering (July 27) at the rate of 5 lbs. every day. It is, in my opinion, the best and most prolific Strawberry which we possess, Frogmore late Pine being over a fortnight ago, whereas the Wizard will run on until the middle of August. Gooseberries are a heavy crop, and the fruit large; Black Currants were an extraordinary crop, and the berries large; Red and White Currants also a heavy crop, notwithstanding no manure has been applied to them for five years.—JAMES CLEWS, *Rockingham, Boyle.*

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Rivers's Early Prolific Plum.—This Plum, to which such favourable reference has been made in our fruit reports of this disastrous season, is very largely planted in the pyramidal form, so as to allow of good crops being grown between, at the Sawbridgeworth Nurseries by Mr. Rivers, jun.

Large Apple Trees.—Can any reader give us the measurement of any very large Apple trees? Henry Ward Beecher describes a tree at Peckskill as 14 feet 10 inches round at 1 foot from the ground. Have we larger specimens than this?

Golden Champion Vine.—Have any of your readers who fruit Vines in pots grown this variety? I am told it succeeds in a very perfect way under this system. It would be a noble looking Grape in a pot, as it is, indeed, anywhere. I should feel obliged to anyone who would kindly favour me with trustworthy information as to where it is grown well in pots.—J. M.

Raising Apple and Pear Stocks mixed together.—I read in one of the last numbers of *THE GARDEN* a notice that a kind of Sorbus will grow better mixed with other kinds of trees than by itself; it was observed that this was even the case with seedlings. In the nurseries of Germany and France, Pears and Apples sown for stock are mixed together, and everybody who tries it will find that both, but especially the Pear stocks, grow much better and more vigorous that way than by themselves.—G. WERNING.

THE KITCHEN GARDEN.

VEGETABLE MARROW CULTURE ROUND LONDON.

VEGETABLE Marrows constitute one of the principal summer crops in the immediate neighbourhood of London, and, where soil and other conditions are favourable, they are very productive. They require, however, a rich and substantial soil, liberally manured, and also one that does not readily become parched in summer; therefore light and dry soils are not so suitable for them as such as are heavier. Mr. Poupart, a market gardener at Bermondsey, used to grow Vegetable Marrows there in great abundance, but when he was obliged to move to the neighbourhood of Mortlake, in order to make way for bricks and mortar, he discontinued their culture owing to the expense incurred in watering them, the land being lighter and dryer. Their marketable value is various; sometimes they hardly pay the grower, whereas, at other times they are highly remunerative, much depending on the scarcity or abundance of Peas, French Beans, Cauliflowers, and other vegetables. Last year Mr. G. Steel's first crop became marketable about the first week in June, but he could not command any sale for them, and consequently had to cart the first gathering to the rubbish heap; afterwards the demand became greater, and the price accordingly higher. Early in March hotbeds are erected for producing Vegetable Marrows, Cucumbers, Celery, and other plants from seeds, the Marrows being either sown thickly in pots or pans of common soil plunged in the beds, or broadcast on a bed with a few inches deep of soil placed over the fermenting material. As soon as the plants show two rough leaves, they are pricked into other beds or into pots. The usual method is to prepare a series of frames set on slightly heated hotbeds; on the surface of these place a few inches deep of soil, into which plunge 6-inch pots, filled with common garden mould, to the brims, as thickly as they can be stowed together. Into each of these pots two Marrow plants should be dibbled, and here they should remain till planting time, hardening them off by gradual but increased exposure in fine weather. The first plantation is made out of doors during the first week in April, but the plants make little progress until the end of the month. The ground is marked off in lines for them about 10 feet apart, and each plant is about 6 or 8 feet asunder in the row. Where each is to be planted, a hole about 20 inches deep, and 2 or 2½ feet wide, is dug out and filled with fermenting manure, which is covered over with the soil that has been thrown out in the excavation. Here the plants are planted, the contents of one pot being put in every ridge, and covered over with hand-lights or large cloches. A little earth is at first drawn around the base of the lights, so as to keep all close and free from cold currents of wind, and, in the event of frosty or cold windy weather setting in, mats or litter are also placed around and over the lights. Excited by the heat from the fermenting manure beneath them, and protected from cold overhead, they are almost as snug as in a hotbed, and consequently they soon take kindly to their new quarters, form fresh roots, and begin to grow. When this is the case, the lights are tilted up a little on the south side, by means of half bricks or small flower pots, during favourable opportunities, but shut up at night. When growth, however, begins to make rapid progress, the lights are left a little tilted up at night, so as not to injure the shoots that are pushing forward, and require more room than is afforded under their little glass houses, until finally the lights are entirely removed, which will probably be in the latter half of May. This plantation, when it does begin to grow in earnest, grows most rapidly, and from it fruit is generally cut in the first or second week in June—much certainly depending on the warmth of the season. Large growers have generally from four to six plantations of Marrows, each succeeding the other by a fortnight, so that the last planting is made late in June. The seedlings are all raised on hotbeds, as already described; but I have known instances in which the seeds have been sown in June, in clumps of four, where they are intended to remain permanently in the open fields, and afterwards reduced to two; this plan is, however, a very uncertain one. Until the middle of May the plants are planted out on the manure pits, as in the case of the first sowing; but less care is necessary for them. Where

the supply of lights and cloches is deficient, round vegetable half-bushel baskets are used; but, unless these are covered with mats or litter, in the case of frosty winds the plants beneath them often perish. After the middle of May, lines are drawn on the open fields at the required distances apart, and the Marrows are turned out of their pots and planted in the ground, which received no further preparation than that of a slight digging. If the weather be warm and genial, they generally do well, if cold and wet many of the plants frequently succumb; but the blanks are made up from a reserve stock, which is always at hand to meet such emergencies. Although the distances apart of the first planting is 10 feet by 6 or 8 feet, that of the June plantations is 15 feet by 10 or 12 feet, and the intervening crops are planted at corresponding intermediate distances. The earliest crop is planted on ground just cleared of Radishes and Celery, or, if the Radishes be not cleared at the time of planting, the Marrows are planted in every alternate alley between the beds, thus permitting the Radish crop to be removed at convenience. For the later crops, ground occupied by spring Spinach, Radishes, autumn-sown Onions, Cabbages, or Cauliflowers, forms a good medium. The space between the rows is not lost during the minority of the Marrows, but is cropped to within 2 feet of them with Lettuces, in addition to which there are generally three or four lines of Cabbages or Cauliflowers planted along the centre of the space. Turnips also sometimes form the inter-crop. When the Vegetable Marrows begin to grow, if the weather be dry, little basins of earth are drawn to them with a hole for the retention of water, of which they get a good supply until their foliage covers the ground, and thus prevents speedy evaporation from it. The plants begin to fruit when the vines are 3 feet or so in length, and continue growing and fruiting until frost, drought, or mildew renders them useless. In a dull rainy season, provided it is warm, they thrive apace and fruit heavily; but in a hot and dry one they are short-lived and unprofitable. When they are growing pieces of stone or brick are sometimes placed on the advancing vines or they are pegged to the ground, to cause them to root at the joints and thus afford themselves increased means of support. No care is, however, taken of them as regards thinning the overcrowded vines; but sometimes the growers mulch the ground with litter, which not only enriches it, but preserves its moisture, prevents to some extent evaporation, and keeps the fruit clean from grit. As soon as the plants begin to bear, every fruit is gathered when it attains a marketable size, no matter whether they are sold or not, for if any were left too long it would tend to render the plant less fruitful. They are gathered three times a week, the gatherers being supplied with fruit-collecting baskets, a stick, and a knife. With the stick they turn aside the leaves of the plants in search for the Marrows, and they are thus enabled to go over the ground quickly, and without much bending of the back. When each gatherer has filled a basket, it is carried to the outside of the plantation, and emptied into a heap, or into large baskets or a waggon stationed there to receive them. The trampling the Marrows seem to undergo in the process of gathering does not seem to injure them much. In August some good fruits are selected and marked by inserting an upright peg alongside of each, and these are allowed to remain untouched till ripe, when they are cut and placed within frames or in exposed situations before the sun, so as to become thoroughly ripened. They are afterwards placed in a corner in some of the sheds, to await a convenient season for extracting and washing the seeds. After the middle of September Vegetable Marrows are commonly useless, and the demand for them diminishes; consequently they are not after that time worth the ground they occupy. Sometimes they are cleared off the ground at once, and at other times they are left until frost completely kills them; but in all cases the haulm is raked off and carted to the manure heap before manuring or digging the ground, which is usually planted at once with Coleworts. Custard Marrows are grown out of doors on the same system as early Vegetable Marrows; but, as they are weaker growers than the latter, they are only planted about 8 feet by 6 feet apart. The ground is also, as a rule, mulched all over, and in the event of dry weather they get occasional good waterings.

THE ARBORETUM.

SPIKE-FLOWERED BIRD CHERRY.

(*PADUS CORNUTA*.)

THIS species, the origin of which is unknown, has been grown for many years in the gardens of the Muséum at Paris, where it first flowered in 1869. It forms a very robust and hardy shrub from 13 to 20 feet high, with exceedingly thick, and comparatively short, erect branches, covered with a deep red, almost black, shining bark. The shoots, from their first appearance, are furnished at the base with long and broad stipules of a deep red colour, which continue for a considerable time. The leaves are oval-elliptical in shape, ending in a short point, undulated, a foot or more in length, and nearly 4 inches broad; at first of a rusty colour, but afterwards becoming green and shining on the upper surface, and glaucous underneath. The flowers, which are white, are very numerous, and are disposed in dense erect spikes, as shown in our illustration. This shrub is very ornamental, both in habit and foliage, in which it somewhat resembles *Syringa Emodi* (Wall.), that is, in its general aspect. It flowers in April and May, and is easily multiplied by grafting on the common

Horned Bird Cherry.

Padus (*P. racemosa*—Spach.), which itself is a very handsome shrub, and one that deserves more extensive cultivation.

W. M.

MISMANAGED TREES.

IN suggesting the necessity for uprooting a tree, however much misplaced it may be or injurious to other trees of greater importance, we generally meet with as much repugnance as one would encounter in a proposition for removing a house, unless the individual happens to have some knowledge of arboriculture or is acquainted with the principles of landscape gardening. Hence may be seen in nineteen-twentieths of such places as those under consideration innumerable instances amongst the trees and shrubs of a struggle for life that goes on until a portion, and generally those of the greatest importance, die, leaving those behind half killed and in a condition from which they never recover, through the effects of the fight for food and air in which root and branch have so long been engaged. The fatal effects of this overcrowding are most apparent after seasons such as the present, when the comparative absence of water in the soil through the spring is followed by a hot, dry, rainless summer. Throughout the country, in extensive tracts of land, resting on a sand or gravelly stratum, the soil at the present time in which the roots of the trees are placed is as dry almost as the dust

on the surface, and which the ordinary rainfall of any single season will never moisten. Where trees are too much crowded in dry seasons their roots extract the moisture from the sub-soil to such an extent as almost to preclude the possibility of its afterwards becoming moistened deep down, where the principal feeding roots exist. Frequently in removing trees so placed even after very wet seasons, I have found that when the first 2 feet of the surface soil were removed the earth underneath was as dry as dust—the water evidently having found its way further out from an apparent inability to enter the dry impervious mass, which, in all probability, when once reduced to this state, never after gets sufficiently moistened to be in a condition fit for the support of healthy vegetable life. Again, on the boundary line of places such as those under consideration, how often do we see good intentions defeated through mismanagement. To secure the wanted privacy, or hide something objectionable, trees are planted with little or imperfect preparation of the ground, which just receives a shallow digging, after that they are planted as closely as possible, the intention being to accomplish the object in the least possible time, forgetting that, however good the land may be, there is still a limit to its capabilities in supporting vegetable life. In exposed situations sufficiently close planting is necessary, the hardier trees acting as nurses to such as are more tender; but too often we see the nurses, instead of being removed when their services have ceased to be required, allowed to remain all intergrown, until the under branches of the whole are destroyed, leaving the weakly attenuated stems standing like a plantation of clothes props, showing most objectionably their inability to fulfil the purpose for which they were planted. In all cases such as those in question the preparation of the land should be of a nature to give a reasonable chance for the well-doing of the trees after they have been planted. This cannot possibly be done unless the ground is trenched 2 feet deep, if its character is such as to admit of this depth. The trees should be judiciously selected with a view to their adaptability to the nature of soil and locality, and not too closely planted; as they grow up thinning should be carried out with judgment, and at the proper time. Where the treatment is in accordance with these simple rules, especially as to timely thinning, there need be little anxiety as to the result. I have frequently remarked that a great number of people in planting forget that the trees they plant will ever get any larger; and that others appear to think that everything planted should be allowed to remain for time indefinite. In the inner or more central parts of suburban places, in addition to the mistaken management of the existent trees, any after-planting that is carried out is often of the most objectionable character, not only as to the description of the trees selected, but the position in which they are placed, and the preparation of the ground. In the selection preference is frequently given to Coniferous trees, the whole of our fine deciduous trees being excluded. A greater mistake than this cannot possibly be committed, if we think of the distant future; for the time will inevitably come when the existent deciduous trees will decay, leaving nothing to take their places except such of the Conifers as are ultimately found capable of withstanding the severest frosts experienced at long intervals. Then, as to position; instead of leaving the all-essential open vistas, so indispensable to give breadth, repose, and impart general effect, the dotting system is perpetrated, having much the appearance of an orchard on a large scale, with the trees at more than ordinary, though regular, distances apart. This is a glaring mistake, and one that is much on the increase. If we come nearer the mansion how often do we see a *Sequoia*, or some other monarch of the forest, placed so near that by the time it has fairly begun to show its character it will become a matter of necessity to remove either the tree or the house. In the preparations for planting these trees the common mistake is often made of digging the ground over a considerable depth without anything in the shape of a drain to carry off the water that is certain to accumulate in the newly-loosened soil, which acts as a receptacle for the water that drains into it from the surrounding ground, thus precluding the possibility of the tree so placed thriving as it should do. T. BAINES.

THE BAMBOO IN EGYPT.

A PAMPHLET has been published at Cairo by the Agricultural Department of Egypt, on the Indian Bamboo, which it is said, is being acclimatised there with great success. We append a few notes therefrom:—The gigantic Bamboo, which is of colossal dimensions, growing to the height of 20 metres, with a circumference of 40 or 50 centimetres at the base (say 65 feet high and 15 to 18 inches in circumference), from the joints of which, especially those of the middle and upper parts, grow numerous branches with long leaves, is the most vigorous species of this arborescent plant. It was intro-

duced some years ago into the gardens of the Khedive of Egypt, at Ghéziréh, from whence it has been multiplied in two or three other gardens of Egypt. It was so much admired by the Emperor of Brazil, on his visit to the gardens of the Khedive last autumn, that he expressed his determination to import it into Brazil, and to cultivate it upon the Imperial estates as a shade for animals during the heat of summer. The gigantic Bamboo originates in India and China, and is highly appreciated wherever it is cultivated, being used for posts in pavilions and the houses of the inhabitants. The hollow joints are utilised for carrying liquids, for flower-vases, &c., and in China, and especially in India, for bottles and tobacco-boxes, highly wrought and polished and sold at great prices. The larger stalks are also used for bridges, water pipes, and carts and other vehicles. In fine, the wood is employed in the arts, in a multitude of industries, and for implements of agriculture. This species of Bamboo vegetates with such rapidity that it can almost be said that one can see it grow. Its progress may be seen from day to day, and at Ghéziréh it has been known to grow 9 inches in a single night. A humid soil is congenial to the gigantic Bamboo, although it suffers under a prolonged inundation. It is proposed in Egypt to cultivate it upon the borders of the canals in the vast domains of the Khedive. There is also in the gardens of Egypt another species of Bamboo, believed to be the *Bambusa arundinacea* of Willdenow. It presents the following characteristics:—The stalks are smaller and shorter than the gigantic Bamboo of India; it attains about 12 metres (39 feet) in height; it forms larger tufts or clusters than the great Bamboo, and throws out a greater number of stalks, which are furnished with numerous slender and flexuous branches, bearing ordinarily tolerably large thorns, a little arched at the joints or articulations, and the leaves are smaller than those of the gigantic species, being rounded at the base, lance-shaped, tapering to a point, and a little downy. There is another species of Bamboo which it is proposed to cultivate in Egypt. It attains a height of 5 or 6 metres, produces enormous clusters of canes, about the size of the finger, and makes excellent props for use in horticulture. A plant of two or three years' growth will furnish a hundred stalks, forming a cluster of vast size. The species is the *Bambusa edulis*, so called from the fact that its young shoots are edible, and in China regarded as very nourishing. There is still another species of Bamboo to which the attention of the cultivator in Egypt is called. It is the black Bamboo (*Bambusa nigra*). It is distinguished principally by its slender branches, which are of a fine black colour, and from which canes are manufactured extensively for exportation. Pens are made from the smaller stems, which are commonly used for writing in Egypt.

THE SILVER FIR.

(*PICEA PECTINATA*.)

By C. Y. MITCHIE.

THE common Silver Fir, *Picea pectinata* (Picea of Linnaeus, but Abies of some other writers), is one of the most picturesque and ornamental of forest trees, and in some cases the most handsome of the Conifera. At times it diverges from the beautiful into picturesque and even grotesque. With all deference to Gilpin's admitted good taste, he has evidently failed in displaying it here, when he speaks of the Silver Fir in the following strain:—"The Silver Fir has very little to boast in point of picturesque beauty. It has all the regularity of the Spruce, but without its floating foliage. There is a sort of harsh, stiff, unbending formality in the stem, the branches, and in the whole economy of the tree, which makes it disagreeable. We rarely see it, even in the happiest state, assume a picturesque shape. Assisted it may be in its form when broken and shattered; but it will rarely get rid of its formality. In old age it stands the best chance of attaining beauty." The Silver Fir was introduced from Germany or Switzerland, by Sergeant Newdegate, in 1603, who planted some at his residence at Harefield Park, Middlesex, and which, according to Evelyn's account, became very large trees. It is a tree that attains to an immense size, both in this and other countries, and grows to 150 years of age under favourable circumstances. We are informed by those travellers who have seen it growing in Switzerland, Germany, and France, that it appears to luxuriate under circumstances similar to the Larch, but prefers a rich dry soil, though at times it is found on ground rather poor, but not gravelly. The Silver Fir is propagated chiefly from seed, which is ripe in November; but it can also be readily propagated by cuttings and layers. We have also seen a considerable number of trees that had been blown down with the wind at different periods, which had struck root in the ground all along that side resting upon it; and this not only with young trees, but with others also exceeding forty years old. The roots also possess considerably more vitality than any others of the Coniferous common forest trees, and not only remain longer in a vital

state after the tree is cut down, but make an effort to prolong life, as is seen in the exuding resinous matter around the top of the stool, between the bark and the sapwood. We never observed any tree actually produce shoots (termed stockshots) in the same manner as hard-wood trees do; but in cases where the tree is cut over at such a height above the ground as to leave a few living branches upon the stool, they often produce vertical shoots which would become trees. Another peculiarity of the Silver Fir must be familiar to most foresters, in its proclivity to produce vertical shoots at any part where an accident or injury has occurred, or when the top or limb is broken off. It is in connection with this peculiarity of growth that double tops are produced, for it possesses, in common with hard-wood trees, the quality of producing shoots of two distinct kinds, viz., those that grow horizontally and spreading, termed branches, and those that grow upright, and which constitute the stem or trunk. Probably every other tree as well as that of the Silver Fir possesses that inherent power of producing both kinds of shoots, and only require to be placed under peculiar circumstances in order to develop them; but the Silver Fir undoubtedly possesses it in a much higher degree, and different from all others of the Coniferous class of forest trees, at least the common Scotch Pine, Norway Spruce, and Larch; though the Larch, it must be admitted, possesses it to an appreciable extent. So different, varied, and even conflicting are the accounts given of the culture and success of the Silver Fir, that many persons have been induced to plant it extensively to the exclusion of the Larch, Spruce, and Scotch Pine; while others have been so far influenced on the other side as to have abandoned planting it altogether, each party believing they have sufficient grounds for acting as they do, and are justified in the course they pursue. Without arrogating too much, we shall endeavour to show at least some of the reasons for each party maintaining their own views and acting upon them, and how far each is right in going to the extreme to which they go in either direction.

In almost every county of Scotland, very fine specimens of the Silver Fir are to be met with, growing upon a diversity of soils, and variously situated, both in regard to shelter and altitude. We have seen it grow well upon almost all soils, except gravel. On such gravel at least Scotch Pine, Birch, and Larch, will grow tolerably well upon, Silver Fir appears not to succeed. We have sometimes thought that we knew cases where this rule was violated; but on examining the soil, and especially the sub-soil, we found that although the surface presented gravel, the sub-soil was of clay or sandy loam. The counties of Moray and Inverness are proverbial for their extent of gravelly and sandy soils, and these counties generally are ill adapted for the growth of Silver Fir. In corroboration still of this opinion, we met with Lord L., of B—— Castle, a few months ago, and this nobleman, being eminently versed in forestry, entered into a conversation about the Silver Fir, and his lordship informed us that Silver Fir does not succeed upon his estates in Inverness-shire, but invariably lose their leading shoots at 10 to 20 feet high, and many fail long before that stage of growth. On further inquiry, we found that the soil, where the failures occurred, was of a gravelly and sandy description, which probably accounted for it. We know of some fine healthy growing Silver Firs situated upon very cold and wet clay, and upon such soils they are certainly the finest specimens of any forest trees in their locality. The counties of Dumfries, Peebles, Selkirk, and Roxburgh, comprise soils at once the coldest and most clayey and wet of any in the country; and yet in each of these counties are to be found splendid Silver Firs. Take for example those trees in Mainswood, near Darrisdale, Dumfries, some of which contain 200 cubic feet; or those at Cowhill, near Dumfries, of equal size; on the roadside at Annan; and also at Dumerieff, near Moffat, all of which are noble trees. Or again, look at those splendid specimens at Stobo Castle, and Dawick House, Peeblesshire, or those at Oldhouse of Killearn, Riddell, and Borthwick Brae, and also at Stobs Castle, Branxholm, Wanchope, and many other places that might be named. We have remarked that soils, however cold or clayey, do not injuriously affect but rather favour its growth; and we would next glance at the altitudes at which it is found to succeed. These as may be conceived cannot definitely be ascertained; but we know of large Silver Firs growing at altitudes over 1,000 feet, and we are informed by others that they know of them of immense size at nearly 1,200 feet altitude. Taking therefore the two circumstances together, coldness of soil, and the extreme altitude at which it grows luxuriantly, there can be no doubt as to the hardness of the tree in relation to those influences. In regard to situation, it appears very accommodating, and is found growing well in any. But judging from the appearance of old trees, we are inclined to think it will attain the greatest age and largest dimensions in a northern aspect; and in such, the trees appear less disposed to become forked or double topped, but prolong their upward growth with fewer interruptions; hence becoming taller than in southern exposures. Having stated several

advantages of the Silver Fir, we shall state a few objections to it. After a minute and careful examination of all the various circumstances connected with the culture of the Silver Fir, we are led to the conclusion that those influences which most injuriously affect it are its liability to spring frosts injuring it, which occur after it has begun to grow, and being then exceedingly tender, it is very apt to be injured by the frost. In addition to frost, there are evidently other influences which injuriously affect the Silver Fir, it may be exposure to a low temperature, or it may be easterly winds, or other atmospheric influences. This distinctive influence, be it what it may, so far affects the trees of all ages by causing them first to decay on the top, and ultimately causing the whole tree to perish, that the magnitude which it has assumed has caused no small alarm and loss to proprietors. This influence, which, in the writer's opinion, is different from frost, whose effects are visible to the eye, is succeeded by the insect popularly known as the mealy bug. And with many it has long been the established opinion that it is the cause, and not the result or consequence of a predisposing cause. It is not, however, essential for our present purpose to know which is the primary and which the secondary cause; but it is nevertheless, to be deplored that through this influence the culture of Silver Fir is rendered precarious and uncertain, so much so indeed that many persons have ceased to plant it. Many Silver Firs have doubtless been thrown into disease by being planted upon land in a state of cultivation, or in other words, by being manured. The effects of manure upon certain Coniferae is so hurtful, and often fatal within a very few years, that most people avoid it entirely; but ground is often planted in which both sufficient manure and lime are present to prove hurtful without a ray of suspicion being awakened respecting them; or of the future failure of the plantation, when it occurs, having even a remote connection with the lime and manure present in the soil when planted. Why one tree should decay and another close by it survive and flourish is a matter involved in mystery; but if we consider that in a plantation of any description there are trees that come early into leaf, and others that are late, differing as much as twenty days or more between the earliest and the latest in foliating, we need not be surprised at the different results that take place throughout the whole period of the tree's existence. And in the event of frost being the sole influence which affects the Silver Fir injuriously it is easily discernible how the results are brought about. If, for example, a frost should occur a few days after the earliest plants have foliated, they would, of course, fall its victims, and those later of foliating for that season escape. And, on the other hand, should a frost occur twenty days after the first or earliest plants have unfolded their leaflets, the latest ones in leafing would suffer, while the earliest ones, being to some extent hardened in consequence of being so long in leaf, would, in like manner, escape. A repetition of frosts upon a certain plant may so weaken its constitution as to predispose it to disease; hence frost may produce diseases of which it was little suspected. So much in regard to the culture of Silver Fir; we shall next state some of the uses to which it is put, and its general and comparative value as a timber tree:

First, in the market for railway sleepers there is no difference or distinction made between those of Silver Fir, Norway Spruce, or Scotch Pine; the general price for either in the Glasgow and Newcastle market is 2s. 6d. each, for what are termed 10 inch sleepers, that is sleepers 9 feet long, 10 by 5. They are seldom required to be die square, but must have a face upon the round side 5 inches broad for the chair to rest upon. When clean grown, it is sawn into staves and heading; but as it is generally knotty, it is not fit for that or any other purpose when cut into thin deals, in consequence of the knots falling out, to the detriment of the articles into which it is manufactured. Boards cut out of old mature trees make excellent flooring, especially for bedrooms. If of heart-wood, and put down dry, nor once allowed to become wet after being laid, the seams or joints are not liable to open as is the case with Scotch Pine; but the surface being partly very hard where the knots are, and partly soft where they are not, cause floors without carpets, or where much traversed over, to wear into holes. Boards or scantling of Silver Fir do not warp or twist as Larch or even Scotch Pine does; hence, on that account it is very serviceable for water spouts, troughs, cisterns and such like. It is an excellent wood for any purpose connected with sluices, embankments, or canals, and is specially adapted for making coffer dams. For roofing purposes there is no home-grown wood better adapted, being equally suitable for rafters, joists, beams, and lintels; but its greatest superiority is for soaking, as it does not warp or twist, or spring the nails at the ends or edges, which some other description of wood does; a circumstance which is very hurtful to the roof, as it causes the slates or tiles to get displaced. No wood is more suitable for partitions, especially to cover with paper, as it is not liable to crack and break as Scotch Pine does, nor is it so liable to worm eat as is the sap-wood of Scotch Pine. For roofing stables, breweries, dye-houses, and

other buildings where the breath of animals or steam very shortly affects the wood with dry rot, Silver Fir possesses several peculiar advantages, and lasts twice as long or even longer than Scotch Pine does. It is very well adapted for fencing purposes, especially for posts, and in wet ground remains sound much longer than the sap-wood of Scotch Pine. It is not so suitable for rails (especially top ones) as for posts, as it is apt to break at the knots; but where the wood is clear of knots, and of moderately slow growth, it makes excellent rails for all except the top, which should be of Larch. In manufacturing Silver Fir, it is advisable, as far as practicable, to convert it into scantlings as large as possible, which avoids breakage at the knots. From all we have seen of the Silver Fir, we conclude, that as heavy a crop of it can be grown per acre as of any other description of wood. For example, we to-day examined a group of Silver Firs, and found them growing at an average distance apart of 12 feet, and each tree on an average, containing 30 cubic feet of timber, thus making the value of the crop at the following rate per acre:—300 trees multiplied by 30 gives 9,000 cubic feet, which, at 6l. per foot, is £225. The age of the trees is about eighty years, and they appear to be quite sound and healthy. We know of no trees which, upon the same description of ground, and within the same period of time, would produce so many feet of timber, save, perhaps, the black Italian Poplar, and the Austrian and Corsican Firs; but the rapidity of its growth entails a great profusion of branches which as a consequence, produces coarse and knotty wood. A valuable crop, however, and probably the most so of any would be, say 500 trees per acre, which would necessitate such proximity of the trees to each other as to prevent undue development of branches; hence wood of finer grain and smaller, if not fewer knots. The Norway white wood, which corresponds with our Spruce, is, as may be seen in the boards, thickly but irregularly dotted all over with knots.

Remarks.

1. The Silver Fir may be planted as a mixture amongst hard-wood trees, or rather in groups, or single trees at wide distances apart amongst them, to form a contrast, at once bold and striking, amidst the rounded cloudy tops of the hard-woods.
2. It is a tree very productive of branches if allowed room to develop them, and these in turn produce coarse grained and knotty wood. On the other hand, if much confined, it is apt to contract certain diseases on the top, which dies down several feet, and sometimes causes death to ensue.
3. Its tendency and liability is to blow down with the wind, in consequence of the immense quantity of branches with which it is usually clothed.
4. The great expense of the plants compared with those of Scotch Pine, Larch, or Spruce, and tardiness of growth during the first eight or ten years.
5. The comparatively low prices derived for the wood in market, compared with many other trees that might grow upon the same soil, and occupy similar space.
6. Its liability to contract diseases, some known, others unknown, but all beyond control, and some fatal.
7. Though personally the writer is a great admirer of the Silver Fir, yet, for general forest planting, he objects to it on the preceding and following considerations:—they are, when planting, if he finds soil adapted to the Silver Fir, he plants other trees upon it more certain to grow, and likely to pay better when grown.
8. One great objection to the Silver Fir in the present day is its great liability to be destroyed by rabbits and hares, which are exceedingly fond of its bark, and prefer it to Scotch Pine, Larch, and Spruce. We have seen the Silver Firs selected and destroyed in the midst of those above named without their being at all injured.
9. Another objection to the Silver Fir is, its tendency to become forked and divide into several stems, which the wind so acts upon as to break off. These must either be pruned off at a considerable expense, or left on to the injury of the tree.
10. The knots of the Silver Fir are so excessively hard as to injure almost any sort of tools, and carpenters object to it on that account. The woodmen dread it for their axes, the sawyer for his saws, and the carpenter for his planes and other tools.
11. The knots being so excessively hard, and the other part of the wood moderately soft, it on that account wears into holes which, in floors, are highly objectionable.
12. In consideration of all the objections to the Silver Fir (not ignoring its good qualities), we are personally in favour of planting in its stead *Picea Nordmanniana*, a tree much resembling the common Silver, possessing all its good qualities and avoiding its bad ones, save that its plants are for the present probably six times dearer, but will, it is anticipated, gradually become cheaper.—*Transactions of The Scottish Arboricultural Society.*

The Pottery Tree.—Among the many vegetable products of Brazil the Pottery tree of Para is not the least worthy of note. This tree, the *Moquilea utilis* of botanists, attains a height of 100 feet up to the lowest branches. The stem is very slender, seldom much

exceeding 1 foot in diameter at the base. The wood is very hard, and contains a large amount of silica—not so much, however, as the bark, which is largely employed as a source of silica in the manufacture of pottery. In preparing the bark for the potter's use, it is first burned, and the residue is then pulverised and mixed with clay in varying proportions. With an equal quantity of the two ingredients a superior quality of ware is produced. It is very durable, and will bear almost any amount of heat. The natives employ it for all manner of culinary purposes. When fresh the bark cuts like soft sandstone, and the presence of the siliceous may be readily ascertained by grinding a piece of the bark between the teeth. When dry it is generally brittle, though sometimes hard to break. After being burned, if of good quality, it cannot be broken up between the fingers, a pestle and mortar being required to crush it.

Gas Pipes fatal to Trees.—Cuttings of Willow, the lower ends of which were placed in flasks containing a little water and filled with coal gas, developed only short roots, and the buds on the upper parts died shortly after unfolding in the air. Of ten plants in pots (varieties of *Fuchsia* and *Salvia*), among the roots of which coal gas was conducted through openings in the bottom of the pots, seven died in four months. To show that the plants were killed, not by the direct action of the gas, but in consequence of the poisoning of the soil, several experiments were made with earth, through which coal gas had passed for two or three hours daily for two and a half years. The rootlets of seeds sown in this soil remained very short and soon rotted. A plant of *Dracena* was re-potted in the soil; in ten days the leaves dried up and the roots died. These results sufficiently account for the fact, that trees planted near gas pipes in streets, so often die; the enclosing of gas pipes in wider tubes, having openings to the air, and through which currents could be maintained by artificial means, has, therefore, been recommended as a remedy. Such a plan is still more to be recommended on hygienic grounds, since it has been shown, that infiltration of coal gas through the soil, takes place even into houses not supplied with gas.—*Scientific American*.

The Hatchet-leaved Thujopsis (*T. dolabrata*).—Indigenous to high but sheltered valleys in Japan, and frequently met with in cultivation in that country as well as in China, both as an ornamental tree and for its timber, which, from its closeness of grain and durability, is highly valued, and used for a great variety of purposes. It is described as forming in Japan a lofty, handsome, conical tree, with vertical branches, gracefully drooping at the points; the branchlets numerous, much compressed, and abundantly clothed with flat scale-like leaves regularly imbricated, of a bright glossy green colour on the upper, and silvery on the under, surface. This grand species was first sent to Britain in 1851, having since been widely distributed, and exposed to the rigours of our winters in the open air without injury. It makes most progress in strong loamy or peaty soils, moderately moist, and prefers a shady situation. A fine variegated variety of this species was sent home from Yeddo, Japan, in 1861, by Mr. Fortune, who found it cultivated in gardens. This pretty plant has the branchlets more or less freely tinted with pale yellow. It has proved to be equally hardy and of as free growth as the parent, and is well worthy of a place in the most select collection.—*Gardener*.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Branch-shedding in Trees.—The Aspen (*Populus tremula*) sheds its branches in hot weather more suddenly and more frequently than even the Elm. Large limbs break off without the slightest warning. There are some fine Aspens in this neighbourhood.—H. G. WATNEY, *Liss*.

Undergrowth in Woods.—How can I increase Elder and Dog-wood for undergrowth in woods? Should I take cuttings or sow seed, as I want many thousands?—K. B. [The best way of increasing Elders and Dog-wood is by cuttings, inserted in rows on well-dung ground in the autumn or spring. It would be best for you to obtain the advice of a practical nurseryman previous to commencing on such a large scale as that you suggest.—Ed.]

Extraordinary Growth of a Tree.—The following are the dimensions of a Fever Gum tree, nine years old, grown on the grounds of Gen. Vallego, thirty-five miles north of San Francisco. The tree occupied a place among his Orange and Olive trees, and approached too near his house. Not wishing to take the chance of having a severe wind throw the sapling across his house, he proceeded to lay the nine-year-old prostrate, and in that position a tape line determined it to be 96 feet from root to top, and a cut sawed off, 4 feet above the roots, showed the diameter to be 19 inches one way across the stump, and 17 inches at a right angle the other way.—*Cultivator*.

Shrubs to Flower in Autumn.—I should like to have the names of a few flowering shrubs that would blossom in the autumn, with hints about the kind of soil best suited for each. The bank where they are to be placed is partially shaded by Oak trees, and the climate so mild that a small *Cornelia* has survived the winter without protection.—M. L. W. [Japan Privet, *Rhus Cotinus*, *Sorbus*, and *Hydrangeas* in variety, *Yuccas*, *Fuchsias*, *Menziesia cuneata*, many hardy *Heaths*, *Clematis flammula*, *tubulosa*, and others, *Lycosterna formosa*, *Escallonia* in variety, and *Calceanthus occidentalis* are all autumn-flowering shrubs which will succeed in ordinary soil, with the exception of the hardy *Heaths* which succeed best in peaty soil.—Ed.]

THE MUSIC OF TREES.

THE sounds and motions of trees constitute subtle but important elements of pleasure. It is not enough that a tree have a comely form as a whole; that it cast a dense shade in the sultry days of summer; that, perhaps, it yield a nut or fruit; and that, finally, when it gives up its life to the inevitable axe, its prostrate trunk shall furnish good timber. Besides these uses of comfort and of economy, a tree, like a rich-hearted person, has a hundred nameless ways which we hardly stop to analyse, but which, were they suddenly taken away, we should miss. The murmuring of trees is profoundly affecting to a sensitive spirit. In some moods of imagination one cannot help feeling that trees have a low song, or a conversation of leaves. They whisper, or speak, or cry out, and even roar. No one knows this last quality so well as those who have been in old Oak forests in a storm, with violent wind. A dense forest opposes such a resistance to the free passage of the air, that the sound is much deadened. But in a park or Oak-opening, where spaces are left for the motion of the air, and among open-branched trees, a storm moves with such power and majesty, that not even the battles of thunder-clouds are more sublime, and, under certain circumstances, it becomes terrific. At the beginning of the tempest, the trees sway and toss as if seeking to escape; as the violence increases, the branches bounce back, the leaves, turning their white undersides to the light, fairly scream. The huge boughs creak and strain like a ship in a storm. Now and then some branches which have grown across each other are drawn back and forth, as if demons were scraping infernal bass-voles. Occasionally a branch breaks with a wild crash, or some infirm tree, caught unawares in a huge puff of the storm, goes down with a crashing fall, and with a thunder-stroke when it reaches the ground. I would go farther to hear a storm-concert in an old forest, than any music that man ever made. No one who is familiar with forest sounds but is sure, when he hears Beethoven's music, that much of it was inspired by the sounds of winds among trees. There are milder joys, however, in tree converse. Only this morning I awakened to hear it rain. That steady splash of drops which a north-east wind brings on is not easily mistaken. I flatter myself that my ear is too well trained to all the ordinary sounds of Nature to be easily deceived. I rise, and throw back the blinds, when lo! not a drop is falling. It is the wind in my Maple trees. I had thought of that, and listened with the most discriminating attention, and was sure that it was rain. Twice we lived in houses built on the edge of the original forests. These had been thinned out, and recesses opened up. It happened in both cases that an Ash and a Hickory had been left, which shot up, without side branches, to a great height. The trunks were supple and tough. Whenever the winds moved gently, these long and lithe trees moved with singular grace and beauty. As there was no perceptible wind along the ground, the movements seemed voluntary. And yet there was in it that kind of irresolution which one sees in sleep-walking. But as soon as the breath became a breeze, the wide circles through which these rooted gymnasts moved was wonderful. They seemed going forth in every direction, and yet surely and quickly springing back to position again. And in every motion, such was their elasticity, they manifested the utmost grace. The sighing of winds in a Pine forest has no parallel sound except upon the sea-shore. Of all sounds of leaves it is the sweetest and saddest, to certain moods of summer leisure. The Pine sings, like the poet, with no every-day voice, but in a tone apart from all common sounds. It has the power to change the associations, and to quicken the poetic sensibility, as no other singing tree can do. Everyone should have this old harper, like a seer or a priest among trees, about his dwelling. Under an old Pine would naturally be found the young maiden, whose new lover was far across the seas. In the sounds that would descend she could not fail to hear the voices of the sea,—the roar of winds, the plash of waves running in upon the shore. Every country place should have that very coquette among trees, the Aspen. It seems never to sleep. Its twinkling fingers are playing in the air at some arch fantasy almost without pause. If you sit at a window with a book, it will wink and blink, and beckon, and coax, till you cannot help speaking to it! That must be a still day that does not see the Aspen quiver! A single leaf sometimes will begin to wag, and not another on the whole tree will move. Sometimes a hidden breath will catch at a lower branch, then, shifting, will leave that still, while it shakes a topmost twig. Though the air may move so gently that your cheek does not feel it, this sensitive tree will seem all a-shiver, and turn its leaves upward with shuddering chill. It is the daintiest fairy of all the trees. One should have an Aspen on every side of his house, that no window should be without a chance to look upon its nods and becks, and to rejoice in its innocent witcheries. I have seen such fair sprites, too, in human form. But one does not get off so easily, if he sports too much with them. The Aspen leaf makes no wounds. Its frolics spin no silken threads which one cannot follow, and which will not break!

The musical qualities of trees have not been considered enough, in planting around our dwellings. The great-leaved Magnolias have no fine sound. Willows have but little. Cedars, Yew-trees, and Lombardy Poplars are almost silent. It is said that the Lombardy Poplar is the male tree, the female having never come over. It is very likely. It is stiff enough to be an old bachelor. It spreads out no side branches. Its top dies early. It casts a penurious shadow.

H. W. BEECHER.

THE HOUSEHOLD.

SCIENTIFIC TESTIMONY IN FAVOUR OF FRUIT AND VEGETABLE FOOD.

PROFESSOR OWEN.—“The apes and the monkeys, which man nearly resembles in his dentition, derive their staple food from fruits, grain, the kernels of nuts, and other forms in which the most sapid and nutritious tissues of the vegetable kingdom are elaborated; and the close resemblance between the quadrumanous and human dentition shows that man was, from the beginning, adapted to eat the fruit of the trees of the garden.”—“*Odontography*,” p. 471.

BARON CUVIER.—“The natural food of man, judging from his structure, appears to consist principally of the fruits, roots, and other succulent parts of vegetables.”—“*Animal Kingdom*,” p. 46 (Orr, London, 1840).

M. DAUBENTON.—“It is, then, highly probable that man in a state of pure nature, living in a confined society, and in a genial climate—where the earth required but little culture to produce its fruits—did subsist upon these, without seeking to prey on animals.”—“*Observations on Indigestion*.”

LINNEUS.—“This species of food [fruit] is that which is most suitable to man; which is evinced by the series of quadrupeds; analogy; wild men; apes; the structure of the mouth, of the stomach, and the hands.”—“*Linneæi Amonitates Academicæ*,” vol. x., p. 8.

RAY.—“Certainly man by nature was never made to be a carnivorous animal, nor is he armed at all for prey or rapine, with jagged and pointed teeth, and crooked claws sharpened to rend and tear; but with gentle hands to gather fruit and vegetables, and with teeth to chew and eat them.”—“*Evelyn's Acetaria*,” p. 170.

BELL.—“It is, I think, not going too far to say, that every fact connected with the human organisation goes to prove that man was originally formed a frugivorous animal. . . . This opinion is principally derived from the formation of his teeth and digestive organs, as well as from the character of his skin; and the general structure of his limbs.”—“*Anatomy, Physiology, and Diseases of the Teeth*.”

HALLER.—“This food, then, which I have hitherto described, and in which flesh has no part, is salutary; inasmuch that it fully nourishes a man, protracts life to an advanced period, and prevents or cures such disorders as are attributable to the acrimony or grossness of the blood.”—“*Elements of Physiology*,” vol. vi., p. 199.

HUFELAND.—“The more man follows Nature, and is obedient to her laws, the longer will he live; the farther he deviates from these, the shorter will be his existence. . . . Plain, simple food only, promotes moderation and longevity; while compounded and luxurious food shortens life. . . . Instances of the greatest longevity are to be found among men who, from their youth, lived principally on vegetables, and who, perhaps, never tasted flesh.”

LIEBIG.—“Grain, and other nutritious vegetables, yield us, not only in starch, sugar, and gum, the carbon which protects our organs from the action of oxygen, and produces in the organism the heat which is essential to life, but also in the form of vegetable fibrine, albumen, and caseine, [the elements of] our blood, from which the other parts of our body are developed. Vegetables produce, in their organism, the blood [matter] of all animals; for the carnivora, in consuming the blood and flesh of the graminivora, consume, strictly speaking, only the vegetable principles which have served for the nutrition of the latter.”

DR. CARPENTER.—“We freely concede to the advocates of vegetarianism that, as regards the endurance of physical labour, there is ample proof of the capacity of what is commonly called the vegetable regimen, that is, abstinence from flesh meat, to afford the requisite sustenance. . . . We are inclined, then, to believe that a purely vegetable diet, if it contains a due proportion of oleaginous matter, is capable of maintaining the physical powers of the body at their highest natural elevation, even under the exposure of the extreme of cold,” &c.

DR. CULLEN.—“I am firmly persuaded that any man who, early in life, will enter upon the constant practice of bodily labour and of abstinence from animal food, will be preserved entirely from gout. . . . The cure [of rheumatism] requires, in the first place, an antiphlogistic regimen; and particularly a total abstinence from animal food, and from all fermented and spirituous liquors.”

GARDENING FOR THE WEEK, AND AMATEUR'S CALENDAR.

The Flower Garden and Pleasure Grounds.

It is hardly necessary to say that the present season, on account of its great drought, has been by no means favourable for the flower garden. The rainfall has been exceedingly partial as well as deficient; and many instances have occurred where, in certain localities, considerable falls of rain have been experienced; while in others, removed by a distance of only a mile or two, no fall has taken place. It may give an idea of the drought experienced in this part of the country to know that the rainfall of the first seven months of the present year amounts to only 6·61 inches. The season, however, has afforded ample opportunities to judge of the great advantages to be derived from an extra depth of soil, and also of a system of mulching wherever this is practicable, as, in too many instances, watering without this really avails but little. Notwithstanding the arid and ungenial character of the season, some varieties of bedding plants are succeeding even better than could have been expected, and notable among which are the Ivy-leaved and hybrid Ivy-leaved Pelargoniums, reference to which was made in a former calendar; while the failure of the yellow bedding *Calceolaria* in many localities is a circumstance, however much it may be regretted, unlikely to cause much surprise; indeed, the total exclusion of this plant from the parterre has almost become a settled question with many cultivators, and is only postponed from year to year on account of the difficulty of finding a suitable substitute, or one likely to supply the desired colour. Many varieties of annuals and other plants have been recommended for this purpose, but none of them free from grave objections; among the best are *Tagetes signata*, and some of the various sorts of dwarf French Marigolds, the *Gaillardias*, *Calliopsis*, or (*Eurothera Drummondii*), all of which have, however, a more or less weedy appearance, and in all respects fall far short of the *Calceolaria*, when seen in a flourishing condition; but, in the meantime, a fair trial might be given to the varieties of yellow bedding Pansies, *Tropeolum compactum*, and some of the orange and yellow-flowering Lantanas. Though the flower-garden may be less attractive than it usually is at this season, the various routine operations must nevertheless be adhered to, and every effort should be made to make neatness and order compensate, as far as possible, for any deficiencies which there may be in floral display. Go over flower-beds daily, or as frequently as may be necessary, and pick off decayed flowers and leaves. Finish the clipping of Box and other edgings, if this is not already done, and sweep and roll Grass belts and gravel walks as often as is found necessary. Push on the propagation of bedding plants as fast as possible, wherever cuttings can be obtained. Put in cuttings also of various sorts of hardy herbaceous plants, wherever it may be considered necessary to increase the stock of the same—such as the various hybrid Phloxes (all of which are exceedingly beautiful), Pentstemons, and Mule Pinks, all of which may now be struck from cuttings in a close frame, along with Verbenas and other bedding plants; and they may be wintered in the store pots, from which they can be transferred to beds or borders where they are intended to flower, in spring, or, to further forward them, they may be potted off singly in spring, and planted out about the beginning of May. Collections of valuable hybrid Phloxes, Pentstemons, Delphiniums, and Mule Pinks, should be cultivated in every garden, as they are all beautiful decorative plants, and always afford an abundant supply of cut flowers during a very considerable portion of the season; and the improvement which has been effected in them of late years is very remarkable.—P. GRIEVE.

Roses.

Maréchal Niel is the finest yellow Rose we have in cultivation, but being a free grower and bad one to flower in some localities, and having grown it in pots and out of doors on its own roots, Briar, Gloire de Dijon, and other stocks, a few remarks as to the best way, and the stocks I have flowered it on most successfully, may be useful to amateurs wishing to grow this fine Rose; I will, therefore, commence by taking the Maréchal on his own roots. I have a Rose-house, with the spans facing north and south, with a pit for fermenting materials, and bottom-heated by hot-water pipes. The paths and stages all round are 2 feet 6 inches wide. I took off a cutting from one of the grafted plants, which, when rooted, it was potted into a large 60-pot, in March, 1873, and then plunged in Cocoa fibre in the Rose-house and grown on up to the middle of July, during which period it received several shifts, and at the end of July I gave it its last shift for the season. By this time the plant had two shoots 6 feet long. I had the pot placed near a south fence, and the shoots nailed to the fence, in which position it remained

till the beginning of November, receiving an occasional watering. It was then removed, with other Tea Roses, into cold pits. At the latter end of January, 1871, I had it removed to the Rose-house, and placed the pot on the south stage of the house, as near the front-lights as I could place it. I then had two lines stretched horizontally, about 1 foot apart, along the front rafters, to which I tied the two shoots, without pruning them; but previous to doing so, I had the Roses washed with a solution of weak Gishurst compound. From that plant I have cut over one hundred fine blooms this season. It commenced flowering in March, and has had three or four successions of blooms up to the end of July, all of the blooms being fit to exhibit at any exhibition of Roses. (The *Maréchal* does not succeed so well on its own roots planted out, as in pots.) I also had two plants, started in the spring of 1873, specially picked out, and worked on the Briar stock; one was budded, and the other was grafted on the French system; they both made excellent growth; the grafted plant seemed to do the best for some time, but when removed from the house to the open air, by some means or other, the graft was broken off, so I am quite certain the grafts do not succeed for such strong Roses, except they are potted deep. The budded plant made excellent growth, and it was quite as good as the plant on its own roots, and one thing I must mention, that the Roses that were cut off the Briar were of a deeper colour. The Rose was trained on front wires in the same way as the one on its own roots, and received the same treatment. *Maréchal Niel* succeeds well planted out worked on the Briar, but I do not like grafted plants. I bought twelve grafted plants, and not one is alive now. Standards especially, bloom freely, and are very deeply coloured. I have dwarf ones worked for trellis-work. Care ought to be taken in selecting good healthy stocks, and do not prune too freely, only cut out weak shoots, leaving the strong growth to flower.—H. G.

Indoor Plant Department.

To soft-wooded conservatory plants in flower, pure water only should be given; but to such as are making growth, occasional applications of manure-water may be given. *Lapagerias*, both red and white, are now in great beauty, as are also *Passion-flowers* and *Fuchsias* on trellises. Lilies placed amongst the green masses of *Camellias*, *Azaleas*, *Acoelias*, &c., have a pleasing effect, and few plants can be more charming for fronts of borders than *Hydrangea paniculata*, *Agapanthus umbellatus*, *Vallota purpurea*, *Trachelium caeruleum*, and *Plumbago capensis*. Keep up a good succession of *Gomphrena globosa*, *Balsams*, *Cockscombs* and other *Celosias*, *Rhodanthe Manglesii*, *Begonias*, *Petunias*, *Heliotropes*, *Achimenes*, *Fuchsias*, *Pelargoniums*, *Asters*, *Schizanthuses*, *Zinnias*, *Coleuses*, and others. Remove plants, the beauty of which is over, to frames; in the case of tall straggling plants, however, it may be more desirable to save cuttings of them than to preserve the old plants through the winter. Annuals may be consigned to the rubbish-heap as soon as their flowers become faded, unless seed-saving is an object. See to repairs in the way of glazing and painting, and put everything in good order before winter sets in. The general stock of hard-wooded plants in greenhouses, such as *Coronillas*, *Cytisuses*, *Heaths*, and *Azaleas*, must be freely exposed, if in frames, to atmospheric influences, but if cut off doors they should be screened from strong sunshine by plunging the pots in Cocoa-nut fibre or ashes, and by laying the pots on their sides in the event of heavy rain-falls. The earliest started *Fuchsias* if now cut back, rested, re-potted, and started into growth, make fine late-blooming plants, but young plants are preferable. Transfer a few Lilies to a house with a north and cold aspect, so as to keep them as late as possible in coming into bloom. The earliest ones should now be kept quite dry and in a cool shady place, and succession ones just moist enough to prevent the leaves from shrivelling until the stalks turn yellow, when the bulbs may be kept altogether dry. Of *Amarantuses* have a good stock, as they are very effective mixed amongst flowering or white-leaved foliage plants, such as *Centaureas*. A *salicifolius* will now be at its best, and in order to maintain a good brilliant colour in the leaves, keep the plants near the glass and in an airy position; a little peat put into the soil in which they are growing serves to increase brilliancy of colour in *Amarantuses*, *Coleuses*, *Iresines*, *Alternantheras*, and similar plants. Be very careful in watering plants of *Gomphrena globosa*; for they are apt to damp off quite suddenly at the neck, and to become useless; a little charcoal dust placed around the base of the stem has been found to be a good preventive of this malady. Permit the earliest started hybrid *Begonias* to go gradually to rest, for although they might continue to flower for a short time, yet their habit would be of such a loose and straggling character that young plants would be vastly superior to them. Sow *Cyclamens* in a very gentle temperature and light soil, for, by sowing now, excellent flowering plants will be obtained when the seedlings are fifteen months old. Attend to the pricking off and potting of *Calceolarias*, *Cinerarias*, and Chinese *Primulas*, and pot *Anriculas* and

place them in a frame with a northern aspect. Graft a few *Epiphyllums* on *Pereskia* stocks, and propagate a few of the latter by means of cuttings. Unfasten the ligatures of *Camellias* and *Azaleas* that have "taken," and re-pot the plants as soon as practicable. In stoves fine foliage is now more predominant than flowers, therefore the plants should be arranged accordingly, giving a light and prominent position to highly-coloured plants. Syringe every fine day, water plentifully but moderately, and shade thinly from strong sunshine. Pot singly young *Gloxinias* raised from cuttings made of the leaves, or seedlings, and gradually dry off those that have done blooming. Such plants of *Achimenes* as are exhausted place on a dry shelf, and keep them pretty dry. Some *Eranthemums*, *Gymnos-tachyums*, *Sonerilas*, *Cytodeiras*, *Bertolonias*, &c., if rooted at their several joints, may be separated, and each division to which roots are attached, potted singly. *Euphorbia jacquiniiflora* and *Poinsettia pulcherrima* should have a position close to the glass in a moderately warm place. Encourage the growth of *Gesneras* of the *Exoniensis* section; they make fine blooming and ornamental plants from October throughout the winter. Plants of *Clerodendrons* of the *Kiepmferi* and *Fallax* section must be stored away in some dry place.

Orchids.

Most of the work now to be done in the Orchid-house consists in keeping plants, pots, and stages scrupulously clean and sweet. Watering will require more care and attention as the dull foggy weather commences, especially such pseudo-bulbous kinds as have completed their season's growth. Others, as *Vandas*, *Aerides*, *Angraecums*, *Phalenopsis*, and *Cypripediums*, will always require a liberal supply, even during the depth of winter, and the last-named, together with *Disas*, and such of the *Dendrobies* as are making their growth, should be gently dewed with the syringe in the middle of the day during bright mild weather. *Laelias*, on blocks, and *Sophranitis* will now require constant attention, and must be repeatedly plunged or dipped in tepid water, so as to thoroughly moisten the *Sphagnum*, which will then continue in a genial state, and foster the increase of root-growth and the consequent vigour of the plants. Carefully renew the top growth of *Sphagnum* in all cases where it has failed since the general re-potting took place. The Moss used for this purpose should be carefully picked over, bit by bit, so as to remove all rubbish, insect pests, and slugs. Where *Cattleyas* have made their growth, every precaution should be adopted to prevent their again starting into growth before the turn of the year. This may be done by keeping them moderately cool and dry at the roots, and by admitting plenty of fresh air daily during fine weather. The bottom ventilators may be left open during mild nights, and this treatment conduces to produce a fresh and healthful appearance among the plants that cannot be attained in any other way.—F. W. BURBIDGE.

Indoor Fruit Department.

As soon as Pines are cut in any of the pits, get the latter thoroughly washed, cleaned, and repaired, the wood-work painted, and the walls lime-washed. The heating apparatus should likewise be seen to, and all got into good working order. Remove such suckers as are good and strong as soon as they are ready for separation, with a heel of the old wood attached to them if practicable; pot them at once, and start them in a kindly temperature. Crowns, as a rule, should be avoided unless for the perpetuation of new or scarce sorts, and then only those from first-class fruits ought to be chosen. No matter at what season suckers are ready, they should be potted. Shift all plants that require it, shade them and keep them a little close for a time, and dew them overhead with tepid water through a fine rose or syringe at shutting-up time. Those intended for early summer fruiting should now have their pots well filled with roots, and should be kept moderately dry, but at no season of the year absolutely so. Such plants as are about to throw up their fruits enjoy a good growing temperature and a kindly bottom-heat, and for this purpose fresh linings and plunging may be necessary. Remove the lights if practicable from the earliest Vineries in which all the wood is thoroughly well ripened and the fruit cut, and paint and repair the house. Where Grapes are ripe and hanging, precautions should be taken against the ravages of wasps and other predators, either by placing the clusters in little muslin bags, or if convenient, covering over all openings for ventilation with sheets of tiffany, hexagon netting, or frigi domo. A somewhat dry atmosphere is necessary where Grapes are ripe and colouring, but still guard against too much aridity. In late Vineries where the berries are swelling, give air night and day, and maintain an equable temperature by means of a little fire-heat, which dispels stagnant damp in dull weather, and renders the atmosphere sweet and healthy; give also abundance of water, and sometimes manure-water, to the borders, and liberally damp all paths, walls, and floors during the day, otherwise shrivelling soon sets in, and red spider

makes its appearance. The earliest pot Vines will now have their canes well browned off and thoroughly matured, and as soon as this is the case they may be turned out of doors and set in well sheltered places where their rods can be kept erect. Turn the pots on their sides when it rains heavily. Other pot Vines may be kept in a growing condition until they are ripe, when they should be treated like the earliest ones. In order to give late Peaches and Nectarines every chance of ripening properly, fully expose them to the influence of the sun. Trim out all shoots not required for next year's work, so as to thoroughly ripen those retained. Where the fruit has been gathered, and the wood is well matured, ventilate the houses as much as possible night and day, and syringe with a solution of sulphur for the eradication of red spider, and use some dissolved soft-soap or Gishurst compound in the water when syringing for the destruction of scale. Keep the borders moderately moist, for drought under any circumstances is exceedingly deleterious to the trees. The second general crop of Figs will now be ripening, and consequently the atmosphere should be kept a little drier than usual, and the house more freely ventilated so as to improve the quality of the Figs. Trees swelling their fruits must be liberally fed and syringed, and scale and other vermin eradicated. Prevent over-luxuriance in Melons by means of kindly treatment and a little ventilation at night as well as during the day, in preference to stinting the supply of moisture and pinching severely. However, their growth must be regulated and held in check, and attention must be paid to the fertilisation of the blooms. To those whose fruits are swelling, give heavy applications of water, and occasionally some manure-water. If the plants for winter fruiting are not yet planted, no time should be lost, for late-planted ones seldom give much satisfaction. Seed of Cucumber plants for winter fruiting should now be sown, and cuttings struck from present fruiters to succeed them. Worn out plants may now be cut in rather severely, the borders mulched and well watered, and the linings renewed; the plants will then soon make a fresh start, and bear well for some time. Attend to the usual routine of thinning the leaves, shoots, and fruits whilst in a young state.

Hardy Fruit.

Each day now the sun begins to lose power, and we have only a few more weeks left of sunshine of sufficient force to mature the wood of our fruit trees. This fact should now govern all our practice in the fruit garden. Each superfluous shoot, in the case of wall trees, should now be removed; for, where the wood is laid in at all thickly, and the leaves are well developed, it is nearly all densely shaded. It continues green instead of brown; now green wood means weak wood, with great buds and an excess of sap in them. The two together are capital food for the frost, and many a deep cut have I seen it make in such wood, producing running gum and cankered blotches innumerable. The best means of steering clear of such evils, and others that are pretty sure to come, with the winter's cold and the erratic freaks of spring, is to see that the wood of all fruit trees is thoroughly and soundly ripened in the autumn. Ripe wood is well-nigh invulnerable to cold; its buds have gone safely to sleep, and they have thick, warm, hard nightcaps, in which they repose in safety. But green wood and watery buds are altogether different; they have hardly gone to rest, when the spring flow of the sap begins to rise, and this early rising means sure destruction. That the early bird gathers the worms, is not more true than that early trees are blighted by frost. The fact is, those least matured in autumn are the first to move in spring, and the tenderest during winter. The fruits will mostly ripen without much of our help, but it is different with the wood. Even the colour and flavour of late Peaches, Plums, and Pears are often much improved by the removal of superfluous branches. The wood is still more benefited. Occasionally strong growing fruit trees should be partially root-pruned this month. Nothing hastens maturity like the knife on a few leading roots; but such early root-pruning must not be carried to excess. If so, we would reap a harvest of shrivelled wood buds, and few fruit-bearing ones. A full crop of fruit I always look upon as the most satisfactory and effective wood ripener.—D. T. FISH.

The Kitchen Garden.

Cucumbers in pits or frames, that are expected to continue in a bearing condition till the end of October, should have the linings partially renewed to stimulate root action; and, as the nights will soon be getting colder, mats should be resorted to to prevent radiation. Any plants that are showing symptoms of exhaustion should be top-dressed with rich soil, and be occasionally watered with liquid-manure, sprinkling them freely with clear soft water on the afternoons of fine days, and shutting up early. Where autumn and winter Cucumbers are in large demand, the first house should soon be planted. By planting early there is no occasion to push the plants

unduly with fire-heat, and they will attain to a strength and firmness of growth that will stand them in good stead when the short dark days come. The best form of house for the growth of winter Cucumbers is a low span-roofed structure running east and west; the sides of the span should be of unequal width, the widest facing the south, whilst the north side need not be more than 4 or 5 feet wide. This kind of house for winter work possesses many of the advantages of the lean-to, with abundance of light, and does not require so much fuel as the full-sized equal span-roof. There are one or two points on the heating of such houses, that I think ought to be briefly noticed and insisted upon. The first is—it is false economy to stint the number of pipes, the number of which of course must depend upon the size of the house. When hot-water pipes become very hot, a dry scorching heat is given off, that acts injuriously upon soft-leaved plants like Cucumbers, therefore, with a liberal allowance of piping, there will be less necessity to force the apparatus in cold weather, in order to maintain the requisite temperature. Another thing that is often forgotten at the time when the pipes are fixed, is having separate valves to regulate the bottom heat, so as to have it under thorough control; I look upon this as an important matter, for an excess of bottom heat has been the cause of many failures. The question as to the best soil for winter Cucumbers, has often been discussed, with the usual variations of opinion. I have at various times used almost all kinds of soil obtainable, but there is nothing better than good turfy loam that has been laid up in a heap eight or ten months, in which layers of stable or cow-shed manure had alternated with layers of turf. This can be obtained on most estates; and I think it is most unwise to go to a great expense to build houses for winter forcing, and then deny a man the few loads of soil requisite for successfully carrying it out. Whatever soil is used, let it be free from wireworms; and a sprinkling of soot will be useful, both for expelling insects and imparting vigour to the plants. Cardoons are not so much grown as they were twenty years ago; perhaps they occupy too much space to be profitably grown in small gardens. In large places, however, where first-class French cookery is appreciated, they will be in demand. There seems to be arising a demand for novelties in vegetables as well as in flowers; therefore, I think Cardoons should have more attention bestowed on them, so as to anticipate the probable requirements of the kitchen. The first lot will soon require earthing up, having first gathered the leaves together and bound them round with hay or straw-bands; hay is generally used, because it lies close. The whole row is then earthed up, packing the earth in firmly in the same way in which Celery is usually done.—E. HOBDAY.

Cottagers' Gardens.

Where Potatoes are making a second growth, no time should be lost in lifting them, as they would, if allowed to remain, soon be rendered worthless. The ground, if dug up directly, will be in good condition for the earliest Cabbage crop, the latest sowing of which may now be made. All hedges should be clipped, and ditches thoroughly cleansed while they are so dry; all will then be in readiness for autumnal rains. Attention must still be given to watering many crops, as the slight showers we have had are very deceptive, and while the surface looks moist the roots may be suffering from drought. Any fruit trees that are heavily cropped will be greatly benefited by a good root watering. Window plants must be kept clear of decaying flowers and foliage, and some stimulant applied in a liquid state to continue the blooming period as long as possible. Leaves are falling early this year, and extra attention will be required to utilise these as manure, and to keep everything neat and tidy.—J. G.

Progress of the New Potato Pest.—Colorado beetles (*Doryphora decem-lineata*) are working eastward. They were quite severe in Wayne, New York, but were comparatively harmless in Wyoming. In Alleghany they were strenuously resisted with Paris-green; they were also noted in Cattaraugus, Delaware, Madison, and Tioga. They were also operating in Burlington, New Jersey. In Butler, Pennsylvania, Paris-green is pronounced a failure; resort was there had to patent preparations, but the most effective method of resistance was to shake the bugs into a box and dispatch them. In Union, Paris-green and lime were also effective. In Adams and several other counties the virtues of Paris-green were utilised by a persistent and intelligent application. In Danphin and Forest Counties the insects appeared to be departing, leaving no great damage behind them, especially upon late plantings. The Department of Agriculture has numerous reports recording the progress of the insect towards the Atlantic. In some counties it appears to be checked by other insects. Great good appears to have come from the prompt and energetic application of Paris-green and other

remedies. The plan of having a paid stato entomologist, adopted by some of the American States, and the prompt information as to the enemy's movements, and the best modes of fighting him, supplied by the excellent American agricultural press, have been of great use in this case. The best remedy that can be recommended is pure Paris-green, mixed with ashes or flour, in the proportion of one part to twelve or fifteen. It should be dusted over the plants in the morning when the dew is on the foliage, and should always be repeated after rains. Three pounds of Paris-green to about 40 pounds of flour, ashes, or air-slaked lime, will answer for an acre of Potatoes.

More London Improvements.—We are glad to learn that the Duke of Northumberland, in consideration of the large sum generously paid to him, without a proper valuation, for his old palace in the Strand, has decided to follow the example of Baron Grant, and transform Trafalgar Square from its present stoney wilderness into a blooming garden. According to the plan submitted for our inspection, Landseer's lions will be surrounded with beds of green and protected by dwarf-railings. Now it is the Duke of Bedford's turn; for such public spirit ought to be infectious.—*Hornet*.

Not a Gardener's Paradise.—A cultivator in the Western United States can hardly be having a sweetly pastoral life of it. A newspaper there sketches his daily troubles:—"At daylight he investigates his corn-hills for cut-worms. Then he gets up an appetite for his breakfast by crushing codling-moth larvae with a hoe-handle. During the forenoon he indulges the Potato-bugs with a solution of Paris green. His post-prandial pleasure is to scald the chinch-bugs. His evening delight is to smudge Peach trees to keep down the curculio. When he wakes to another day of toil, he hears fresh grasshoppers tinkling against the pane."

Middlesex Plants.—Numerous specimens of *Sedum dasyphyllum*, I am informed by Mr. W. G. Smith, have been sent him from Mr. J. T. Clarke, who writes that it grows on very old walls for about a mile round Hillingdon. There can be little doubt that it is planted there. Since the publication of the "Flora of Middlesex" this *Sedum* has also been found in abundance on the left hand wall of Sion Lane, Isleworth.—The Rev. Dr. Hind sends Mr. Trimen, editor of *The Journal of Botany*, specimens of *Pyrola minor* from the Grove, on the east side of Stanmore Heath. It occurs in considerable quantity, covering several square yards, under some venerable trees. He states that there appears to be no reason to suppose it introduced.

Remedies for Stings.—Among the various cures recommended for bee stings are liquid potasse, olive oil, vitriol, laudanum, vinegar, honey, salaratus and water, salt and water, soft soap and salt, raw Onion, tobacco juice, a paste of clay or flour, the expressed juice of any green leaf, or of the ripe berries of the coral Honeysuckle. As animal poisons deoxygenize the blood, their antidotes will be anything that contain much oxygen. The poison of a bee being acid, an alkali must be employed to neutralise it. If, therefore, we were selecting for trial any of the above so-called remedies, we should choose either soft soap or ammonia. But if the individual stung is not very nervous, cold water applied to the wound will be quite sufficient, and it should not be rubbed. One great essential is, if heated, to get cooled as soon as possible, and to avoid becoming heated again for at least two days. Nothing is so apt to make the poison active as heat, and nothing favours its activity less than cold. Let the body be kept cool and at rest, and the activity of the poison will be reduced to a minimum. Any active exertion, whereby the circulation is quickened, will increase both pain and swelling.

Toads in the Garden.—Many persons have a loathing of this really interesting, but certainly not handsome, Bufo, the result of superstition or want of education. It is time we learned that they cannot bite, and if they could, that bite would be harmless. We suppose the fiction that they carry a jewel in their head is no longer believed, Shakespeare to the contrary notwithstanding; yet the latter is more true than the former—indeed, it is half true. They carry two; their eyes, at least, are as bright as any jewels that ever sparkled in a diadem. They are the most innocent of creatures that ever ate indiscriminately anything that had life that they could swallow that came within reach. They are worth more per head to the horticulturist than chickens, even allowing that chickens did not scratch; and, to put our readers thoroughly in good humour, with these insect-devourers, we reproduce the following story by Dr. Harris:—He supposed the odour of the squash bug (*Coreus tristis*) would protect it from the toad; and, to test the matter, he offered one to a grave-looking Bufo, under a Cabbage. He seized it eagerly, but spit it out instantly, reared up on his hind legs and put his front feet on top of his head for an instant as if in pain, and then disappeared across the garden in a series of the greatest leaps a toad ever made. Perhaps the bug bit the biter. Not satisfied with this Dr.

Harris hunted up another toad which lived under the piazza, and always sunned himself in one place in the Grass, and offered him a squash bug, which he took and swallowed, winking in a very satisfied manner. Twenty other fine bugs followed the first in a few moments, with no difficulty or hesitation in the taking or swallowing, though, from the wriggling and contortions, it appeared their corners did not fit well within.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

AUGUST 19TH.

ONE of the most curious plants brought before the floral committee on this occasion was *Decabelone elegans*, sent by Mr. J. T. Peacock, and splendid cut specimens of the gorgeous crimson-lipped *Cattleya Dowiana* came from Mr. Brockett's collection at Muswell Hill. A fine new seedling black Grape, having large well shouldered clusters, and oblong berries of a distinct Muscat flavour, came from Mr. Sweeting, gardener at Sneyd Park, near Bristol. Mr. James Groom, of Henham Hall Gardens, Suffolk, exhibited a large oblong Melon a foot and a half long by about half as much in diameter. It is of a rich deep yellow colour with white flesh. Notwithstanding its coarse appearance, it was found to be of excellent flavour, and is interesting as having been raised from seeds brought home from Africa by Sir Samuel Baker, the well known explorer.

Miscellaneous.—Mr. W. Bull sent *Weigela Lavallei*, a new kind with dark rosy flowers; Mr. Chambers, of the Westlake Nurseries, sent finely-flowered plants of the bright blue double-flowered *Lobelia pumila grandiflora*, to which we have before alluded as excellent for carpet bedding and pot culture. With these came the Californian annual *Diplacus californicus*, with orange or orange-yellow flowers, and specimens of a dwarf-growing variety of the well-known Artillery plant (*Pilea muscosa*); Mr. J. Croucher brought *Aloe Fraskii*, having thick amplexicaul leaves; Messrs. Rollison & Sons, of Tooting, sent a splendid group of cut herbaceous *Phloxes*, the colours being very clear and distinct, and these were much admired; Mr. J. Blackwood, gardener to W. Collinson, Esq., sent *Bonatea speciosa*, an old terrestrial Orchid from the Cape, having green and white flowers in terminal spikes. This plant is remarkable on account of the peculiar arrangement of the pollen masses, which are borne on long stalks similar to those of the large-flowered *Disa*. It is sometimes known as *Habenaria Sandersoni*, and may be seen at Kew. Mr. R. Dean, of Ealing, sent a large white-flowered *Phlox*, named Miss Robertson; and Messrs. Hender & Son, of Plymouth, sent an excellent strain of variegated *Amarantus*, having very brilliantly coloured foliage, the most distinct colours being rich orange, purplish-crimson, and creamy-yellow. Messrs. George Paul & Sons, of the Old Nurseries, Cheshunt, sent some nice stands of choice cut Roses, the blooms being of excellent quality for the season of the year.

Fruit.—Messrs. Lane & Sons, Berkhamstead, sent a seedling Grape of excellent quality; but not quite ripe; the committee, therefore, deferred judgment until it can be shown in better condition. From Messrs. Dobson and Sons, Isleworth, came a brace of white-spined Cucumbers, named Prince of Wales; and Mr. Chambers, also of Isleworth, sent a seedling variety, named Westlake Rival; but neither were considered sufficiently in advance of existing kinds to merit an award. Mr. Brown, gardener to Earl Howe, Gopsall Hall, sent some nice fruit gathered from trees which had been removed last season; and Mr. F. Dancer, of Chiswick, the eminent fruit grower, brought excellent specimens of the *Souvenir du Congrès Pear*. A new Scarlet-runner Bean came from Mr. A. Henderson, of Shrublands; but it was not thought distinct from other varieties.

First-class Certificates were awarded to the following plants:—

Cheilanthes Bergiana (Blackwood).—An elegant Fern, from the Cape of Good Hope. Well worth culture.

Cerasus Mahaleb pendula (G. Paul).—A striking variety of a well-known ornamental flowering tree, remarkable as having an elegant drooping habit.

Cornus alba marginata (G. Paul).—A pretty shrub of moderate growth, chiefly remarkable for the white marginal leaves. A nice addition to variegated deciduous shrubs.

Black Muscat Grape "Sneyd Seedling" (Sweeting).—A new and desirable variety, having large and well shouldered clusters of oblong berries, the flesh being tender, juicy, and of a very rich Muscat flavour.

Hollyhock, Mulberry Gem (W. Chater).—A stout dense spike of deep rich blackish-purple flowers.

Hollyhock, Rose Supreme (W. Chater).—A fine dense bright rosy flower, and a nice addition to these stately plants.

A Botanical Certificate was awarded to Mr. J. Croucher, gardener to J. T. Peacock, Esq., for the curious *Stapelia*-like *Decabelone elegans*, having spinose erect angular stems of a glaucous green colour, and drooping longish bell-shaped flowers of a greenish-yellow colour, profusely dotted and streaked with reddish-purple. It is well figured in the last number of the *Botanical Magazine*, t. 6155.

The Gardeners' Royal Benevolent Institution.—With reference to the articles recently published concerning this institution, a correspondent, who agrees with the inadequacy of the support, nevertheless, considers the payment of a guinea a year to the institution as good an investment as a gardener can make, inasmuch as the payment of this for sixteen years secures his election.

THE GARDEN.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

FLOWER-GARDENING IN HYDE PARK.

By AN ARTIST.

HAVING, in a recent number of *THE GARDEN*, read with much interest the remarks of "An Amateur" on the flower-gardening in Hyde Park and Kensington Gardens, "An Artist" ventures to communicate a few remarks on points not touched upon by "An Amateur," and on some others on which his views slightly differ. On entering Kensington Gardens, and passing the northern end of the Serpentine a welcome improvement in the treatment of the bare ground in front of some of the shrubberies is at once observable. The bareness has been partially clothed with flowers and leafage by means of a copious scattering of mixed seed of the more popular annuals. Enough has been done to show that a thick sowing of mixed annuals along the front of irregular shrubberies will prove itself a successful innovation, as heightening the effect of such plantations without the drawback of a certain amount of formalism which necessarily accompanies the old system of distinct patches of herbaceous plants introduced at regular, or nearly regular, distances from each other; or, the still more objectionable system of "ribbon" bordering. On approaching "the cottage," with its rich and pleasing effect, so justly noticed by "An Amateur," it becomes a question, to one with an eye specially educated in art matters, to ascertain what are the principles which produce the undeniably pleasing effect of the whole; and the result of artistic reasoning was this—that the success did not depend nearly so much upon the extremely perfect production of the pretty geometric mosaic of flowers, in set patterns, as upon the occasional introduction, here and there, without formality, of naturally graceful plants—and to the interruption of the architectural lines of the mass of plants rising high above the window sills, and the partial (not complete) covering of the building with Ivy, each of which features tend to break up gracefully the formality of the geometric system, but above all, it is the situation of this little oasis of brilliant flower-colour, in the midst of a wide expanse of undulating turf, and its embowered site, beneath clusters of great trees (which are among the finest in the gardens), that make it a highly-coloured spot, in the midst of the soft repose of far-spreading green, so universally attractive. On approaching the so-called rock-work, at the southern extremity of the Serpentine, one cannot but feel that our "Amateur" has been somewhat too tender in his otherwise just criticism. The "rock-work" is, indeed, only tolerable where entirely covered; the brick-end and clinker work being lumped together, with unmeaning ups and downs, in that truest type of Cockneyism which is so odious to artistic eyes. The interstices of this "ingenious" piece of work were originally filled with expensive plants, utterly unsuited to the situation, which must, in the aggregate, have cost a large sum of money; and which, after making a very brief display, soon died out, as a matter of course. Their places have been usurped by a few rank-growing things, such as the wild hedge Clematis, stunted Periwinkle, and other things of the kind, assisted by mere weeds, which, however, perform the useful office of partially covering the ugly nakedness of the clinker heap. The irregularity of surface produced by the brick-ends being effected, it ought to be taken advantage of for the display of such sorts of hardy plants as are suited to that kind of situation; and, with the better taste that is beginning to prevail in the decorative treatment of the Park, a great improvement in the aspect of the *soi-disant* rock-work may perhaps be expected. There is a long and important strip of gardening not far from the odious rock-work, which has been raised sufficiently high to conceal the most offensive portion of the backs of a row of mean houses in Knightsbridge; an addition which is certainly a vast improvement upon the former appearance of that portion of the park. Some of the slopes of this piece of raised land are very well managed, and produce a very pleasing effect; but, in several places, a kind of blemish occurs, which is but

too common in works of that kind. The defect alluded to, consists in the fabrication of mere hammocks by way of variety, which have generally somewhat the form of gigantic mole-hills; and, as though to make the unnaturalness of this tasteless device more palpable and call it into notice, there is, in almost every instance, a plant of some kind or other stuck on the apex, like a sprig of Holly in a Christmas pudding. The effect of this is sometimes ridiculous, and the nuisance ought to be abated as soon as possible, by reducing these turf puddings to gentle and natural undulations. Another defect is the spottiness with which the more conspicuous plants are introduced. One or two kinds of Banana, for instance, have been planted out for the summer with very good effect, as giving a semi-tropical aspect to some of the shrubby plantations; but the otherwise successful attempt is marred by dotting these noble plants about in all directions, at about equal distances. Sir Fretful Plagiary, in "The Critic," is represented as introducing the boom of the "evening gun" at a special crisis of his drama, but to his horror, the manager, thinking the effect exceedingly good, determined to have half a dozen evening guns, one after another. "Give them a good thing," said Sir Fretful, "and they run it to death;" and so it is with the Bananas, Palms, &c. Varied groups, or even single plants, in suitable companionship, would have been exceedingly successful, but they are sadly overdone, like the booms of the evening gun. No one can look at the slopes of turf in question, spotted all over with nearly equi-distant shrubs, as thick as plums in a pudding, without longing for some clear spaces of turf, to give repose, and something like the aspect of tasteful design. Another defect, from an artistic point of view, is the bordering of irregular shrubberies with set ribbon lines of flowers, in one, two, or three formal stripes of colour—the glaring border entirely destroying the repose and grace of the shrubs, which are, as it were, tied up in this tawdry cable. If we must have ribbon-borders, the fringe of an irregular shrubbery is not the place for them. The lines of Gnaphalium look bad in the same positions. The forms of the detached flower-beds, again, are often ridiculously bad. The kidney-shape appears to be a great favourite, and so does the heart-shape, and also the crescent-shape; all of which, by abundant repetition, fatigue the eye, and call undue attention to this kind of torturing of flower-bed forms, which ought, on the contrary, to be as simple as possible, when not forming part of a set design of geometric character. Detached beds should always be simple in form, in order that the hardness of their outline may not be brought into unnecessary prominence. The circle is the best of all forms for this purpose, and next comes the oval. So far from seeking to occupy the eye with the flowers themselves rather than by the shape of the compartment in which they are planted, the shape itself seems to have been the chief object of the designer of some of these flower patches. The best shapes for flower-beds are those so simple in outline that the attention is not attracted by the shape at all, but reserved wholly for the flowers and plants. Very objectionable features are the mud-wall edgings. The beds have been puddled round with ridges of earth and cow-dung, in which Echeverias, or Sempervivums, or Sedums have been stuck round, as regular as clock-work, just as children stick pebbles round their mud pies. This is the greatest blemish this year in the gardening of Hyde Park. Everywhere, in looking closely at the beds, the wretched little earth-wall catches the eye. In scores of cases the plants have not fallen over so as to cover these edgings; and, where no succulents were stuck in, they are quite bare. One is glad to see that this system is not spreading; at the Crystal Palace gardens, and elsewhere round London, where the old gently-rounded edge obtains, a much better effect results, and the plants look in better health than when raised by these ugly little banks. It is to be feared that neither our gardeners nor our public are at present prepared for such a sweeping innovation as "Amateur" suggests in the massing; it is, however, already carried out to some extent in the case of the annuals that are so well employed to hide the bare earth in Kensington gardens. There is nothing more objectionable than the brown dug surfaces in our public gardens, and this attempt to cover them is a move in the right direction.

NOTES OF THE WEEK.

— A BUNCH of Black Hamburgh Grapes was shown the other day at the Great International Horticultural Exhibition at Belfast, which weighed 20 lbs. 12 ozs. This was furnished by Mr. Hunter, of Lambton Castle, and exceeds the weight of Speechly's cluster of Syrian by about a pound; setting aside the fact that the latter variety is a much coarser Grape, bearing large clusters under the most ordinary cultivation, the analogy between the two Grapes in this case being similar to that existing between a Queen Pine and a Providence. This cluster is the largest as yet grown in Britain, and, like the celebrated 15 lbs. Providence Pine grown at Gunnersbury by Mills, will long be remembered as a triumph in the history of fruit culture. It will be remembered that Mr. Hunter exhibited a bunch of Black Hamburgh last season, weighing 13 lbs. 4 ozs., a figure and description of which appeared in *THE GARDEN* (see p. 514, Vol. IV.) at the time.

— SOME of the papers allude to what they term a new kind of table decoration, and describe a recent instance of it in the house of a Russian lady in London. The table was entirely covered with Moss—the Fern-like Moss which is plentiful in Covent Garden. There was the usual white cloth, but the only evidence of it was seen in that portion which hangs at the sides of the table. Flowers were profusely introduced, and the effect was altogether unique. This is said to be one of the most ordinary kinds of table decoration in the aristocratic houses of Russia. We have seen much the same kind of decoration carried out by Mr. Wills.

— AN appeal recently made through the press for the preservation, as an open space, of a small piece of land in the east of London, abutting on Victoria Park, has met with success. The Commissioners of Woods had stated that they would accept the sum of £900 for the fee simple of this land, if secured for the public as a part of Victoria Park. Mr. Bryant, of the firm of Bryant & May, has now come forward and has offered to hand over to the Committee of the Park Preservation Society the sum of £900 for the ground in question, in order that it may be purchased from the Commissioners of Woods, and preserved as an open space for ever. It is further stated, that the piece of land thus generously given to the public by Mr. Bryant, would be admirably adapted for a site for the Temple Bar Gateway.

— WE are pleased to note the great abundance of fruit now to be seen daily in Covent Garden Market, and even that of the street barrows is of far better quality than has usually been the case in former years. Pears and Apples are alike of excellent quality, and extremely moderate in price. Grapes of home growth are now augmented by supplies from the Continent (Lisbon). The trade in imported fruit is as yet in its infancy, and is evidently destined, ere long, to influence the prices of home-grown produce in a remarkable degree. When we see that it is remunerative to import fruit from America and the Continent at considerable expense and trouble, the thought naturally suggests itself that it would pay us in more ways than one to grow fruit more abundantly at home.

— CONSPICUOUS among plants in bloom on the rock-work at Kew, is a small example of *Rhexia virginica*, a hardy Melastomad, which bears bright rosy-purple flowers in tolerable abundance. This, by no means common plant, may also be found associated with various hardy Ericaceous plants in Messrs. Osborn's nursery at Fulham. Another desirable plant now in flower on the rock-work at Kew, is *Micromeria piperella*, a member of the Sage family, dwarf and spreading, and bearing a profusion of pretty pink or pale rose-coloured flowers. In the herbaceous grounds a plant of *Clematis aethusaefolia* is likewise flowering nicely. Its blooms are of a creamy white colour, and although not of a striking character, are borne somewhat freely, and the plant is, moreover, desirable on account of its distinctly cut foliage.

— ON Monday next, and the succeeding Mondays throughout September, the beautiful gardens at Heckfield Place, the seat of Lord Eversley, are, by his lordship's kind permission, thrown open to the public on the presentation of tickets of admission, which may be obtained at Mr. Wildsmith's cottage on the common close by. Heckfield is charmingly situated on the highlands of North Hants, five miles from Winchfield Station, on the South-Western Railway, and is surrounded by a finely wooded country and much picturesque scenery. It lies in the centre of such fine places as Bearwood, Strathfieldsaye, Elvetham, and Dogmersfield Park, and, although not so palatial in character as either of these residences, is yet the most beautiful in all that relates to gardenesque effects. Just now the flower beds are at their best, and there is also a beautiful piece of decorative bordering in the kitchen garden, and something very diverse, but equally pleasing, in the sub-tropical bedding around the lakes. The fruit houses, and plant houses, too, have their attractions; one has but to glance within the doors of that fine span-roofed Vinery on the west side of the kitchen garden to see that Grapes can be grown here in perfection. This house is wholly devoted to Lady Downes,

the crop of which is faultless, both as regards bunch and berry. In all departments the utmost neatness prevails, and those, therefore, who may be induced to pay Heckfield an early visit may be assured of a genuine treat.

— THE grounds surrounding the East London Museum are being converted into an ornamental garden, under the superintendence of Mr. McIntyre, the chief gardener of Victoria Park.

— WASPS this year abound in the north of Scotland and in Wales. No one ever remembers having seen so many in one season, and they are at present making themselves very troublesome in every household. Several hives of the honey bee have been killed with them, and in almost every garden the fruit has been destroyed and eaten by them.

— OUR attention has been called to the numerous new forms of the tuberous rooted hybrid Begonias, so admirably adapted for rock-work and border culture. Messrs. Veitch & Sons have many fine varieties planted out on their rockery, a position in which they grow vigorously. One plant has stood out for the last three winters, and is now a great mass, a yard through and about 2 feet high, and as it bears a profusion of bright scarlet flowers, it is a very attractive object.

— GROWERS of what are called Dutch bulbs will be glad to know that the supplies imported this season are unusually fine in quality, being even superior in that respect to those imported last year. Hyacinths, Tulips, and Narcissus, are said to be considerably above the average in weight. This is all the more satisfactory, inasmuch as the quality of nearly all Dutch bulbs, especially Hyacinths, has been on the decline for several years past. Next year we may, therefore, expect our spring exhibitions to be unusually brilliant.

— THE authorities of Paris set up recently a large steam-engine at Clichy to supply the sandy plain of Gennevilliers, on the opposite side of the Seine, with sewage-water. The experiment has proved successful. The *Journal of the Society of Arts* says that the market gardeners are now asking for a fuller supply, and the machinery is not powerful enough for the extension of the service. A good supply of sewage-water is an advantage likely to be fully used by the Paris market gardeners, who, unlike our own, have long been accustomed to water profusely with ordinary water.

— IMMENSE quantities of Plums, Apples, Pears, and other fruit, are being brought to the Tyne by the General Navigation boats from Hamburg, Rotterdam, and Antwerp. Contrary to expectations, the Continental fruit crop is a large and bountiful one, and many thousands of baskets of Plums and Apples, brought thence by steamer to Newcastle Quay within the past ten days, have been sent into the mining and manufacturing districts of Northumberland and Durham for sale. The fruit is fine in quality, and is sold retail at a very moderate price.

— MR. GROOM has sent us from Henham Hall Gardens, Suffolk, a very remarkable Melon, of which the seed was brought from Africa, by Sir Samuel Baker. This Melon is wholly distinct from anything we have seen cultivated in Europe or America. In size it is more like a large Gourd than a Melon, yet it has the true Melon skin, and is beautifully netted on a deep golden ground. Large fruits are not usually distinguished for superiority of flavour, and we were surprised to find on cutting up the fruit in question, that the flavour was of the finest possible quality. Mr. Taylor, of Covent Garden, who, as a judge of fruit, is second to none, also examined the Melon and pronounced its flavour to be of the finest kind; such as he had only previously experienced in Asia Minor and North Africa. We hope that Mr. Groom may be enabled to preserve such a valuable variety true, as it is sure to deteriorate if grown near the kinds commonly cultivated. We hope to say more of this fine fruit and its culture on another occasion.

— AT Anner Mills, the residence of Mr. Clibborn, near Clonmel, the gardener lately found a strange-looking object suspended from a slender branch of an Apple tree. It was nearly spherical, about as large as an ordinary-sized cannon ball, and was streaked all over with the brightest colours. He soon discovered that it was a wasps' nest, but for some time was puzzled to account for its varied tints and singular formation. At length the problem was solved. Mr. Clibborn had, some time before, procured a quantity of long paper "shavings" of different colours—red, blue, green, yellow, and white, which he flung over his Strawberry beds, to protect the fruit from the attacks of birds and insects. A colony of wasps, instead of being "warned off," made frequent visits to these coloured streamers, and, with singular ingenuity, reducing the paper to pulp, soon carried it away for the construction of their nest, which quickly grew under the united efforts of quite an army of these little busy artists. The most wonderful part of their work is the regularity of those undulating lines of colour as they were carried around from side to side. This curious nest has been preserved intact, and it is now an object of much interest to visitors at Anner Mills.

HARDY PLANTS OF THE HIMALAYAS.

THOUGH a good many fine plants from the Himalaya Mountains are tolerably well known in English gardens, yet few, except botanists and travellers, have any idea of the number which still remain to be introduced. With a view of calling the attention of those who have friends in India, and who might easily get seeds and roots from them if they took a little trouble, I should like to mention a few of the most beautiful and curious plants I know of. Some of these I have seen myself, but most are unknown to me, except from the figures and descriptions of Wallich, Royle, Baker, and others. As these works* are to be found in most public libraries, it is unnecessary to give more than an idea of the plants, with their localities, as far as at present known. When it is considered that the whole of Nepal, except the environs of Kathmandu, which were explored by Wallich and his native collectors, and almost the whole of Bhotan and the hills east of it, are still quite unknown to travellers or naturalists, some notion may be formed of the wonderful wealth of the flora of these mountains. It must also be borne in mind that the plants here mentioned, which are likely to prove hardy in England, are only found in the temperate and Arctic zones of the mountains, and that the plants of the sub-tropical and tropical zones are probably three or four times as numerous. It must also be observed, that though a number of plants are common to the whole range, from Kumaon to Sikkim, a larger part of them are more restricted in their range, which may be attributed in a great measure to the difference between the climate of Sikkim and the north-west Himalayas. In the former the rainy season commences in April, and continues until the end of October, almost without intermission, whereas in Kumaon and the hills above Simla, the heavy rains do not begin until June, and though the rainfall is not much, if at all, less than in Sikkim, the winter is colder, and the summer, or at any rate the early part of it, dryer and hotter. Of course the climate, temperature, and rainfall vary immensely in different parts of the mountains, but, as a rule, it may be said that the mean temperature of the region, 8-11,000 feet in Sikkim, and 5-9,000 feet in the north-west, approaches pretty closely the average mean temperature of Great Britain. Most Himalayan trees and plants, especially those of Sikkim, which suffer in this country more from spring frosts and dry summers, than anything else, would probably thrive better in an unheated house, where they could be shaded and syringed constantly during summer. I will commence with a few of the Monocotyledonous plants, as being those in which I am most interested, and also because several of the principal genera have been so well worked up by Mr. Baker, in those able and careful revisions of Liliaceæ and Iridaceæ, which have appeared (and which I hope will continue to appear) from time to time in the *Journal of the Linnean Society* and elsewhere.

Among Lilies, we have already introduced *L. giganteum*, *polyphyllum*, and *Wallichianum*, the latter of which, though possibly hardy in mild localities, is, I have no doubt, much better suited for greenhouse cultivation. Besides these, I gather from Mr. Baker's last paper that there are two species not yet introduced, viz., *L. nepalense* (Don) figured by Wallich in his "*Plantæ Asiaticæ Rariores*," iii., p. 267, belonging to the *Eulirion* group, and found in the west central Himalaya from Nepal to Kumaon; and *L. oxypetalum* (Baker), figured in Bot. Mag. 4731, as a *Fritillaria*, but now, I fear, quite lost in Europe, which grows in Kumaon up to an elevation of 12,000 feet. Of Tulips, only one is known, namely, *Tulipa stellata*, a species resembling *T. Clusiana*, but with larger flowers, and all the segments obtuse. It is found in the north-west at from 5,000 to 8,000 feet elevation, and also in southern Persia. This Tulip is included in Messrs. A. Roze's bulb list this year, but whether they have the true species or not I cannot say.

Among *Fritillarias* we have the well-known *F. rosea* or *Thompsoniana*, usually classed with the Lilies, the right name of which, however, is *Fritillaria macrophylla* (Don), and a nearly allied species, *F. Hookeri* (Baker), from Sikkim, where it was discovered by Dr. Hooker at an elevation of 9,000 to 10,000 feet. Then there is *F. Roylei* (Hook.) figured in "Royle's Illustrations," p. 92, a handsome species with tessellated flowers, ranging from Kumaon to Ladak, at high elevations.

Also *F. cirrhosa* (Don), a species with numerous narrow leaves curled at the tip; it grows in Nepal and Sikkim up to 10,000 feet elevation. *F. Gardneriana* (Wall.), is a one-flowered species found in the same districts as the last, but at a lower elevation. Of *Crocus*, one species only is at present known from Cashmere, which is referred by Mr. Baker to *C. sativus*. Other species will, no doubt, be discovered ere long in the mountains of Afghanistan and Central Asia.

Among Irises I know the following:—*Iris decora* (Wall.), from Nepal and Sikkim, at about 8 to 10,000 feet elevation. This is the plant figured by Sweet, Ser. II, vol. i, pl. 1, as *Iris nepalensis* (Don), and was introduced by means of seed many years ago, but is, I am afraid, quite lost now. It is said by Sweet, to have fleshy roots resembling those of a *Hemerocallis*; the flowers are pale blue, streaked with white, and very pretty. Sweet mentions another very dwarf species from Nepal, somewhat resembling *I. ruthenica*, but I can find no such plant in the Kew herbarium from the Himalayas. *Iris fragrans* is a species from Sikkim of which I know nothing; I have a species under the name from Mr. Wilson Saunders's garden, but have not yet flowered it. *Iris kumaonensis* (Wall.), *longifolia* (Royle III, Him. pl.), a species which appears from the plate to resemble *decora*. It is found in the north-west up to 11,000 feet. *Iris sulcata* (*fasciculata* of Jacquemont)?, found from the Khasia hills up to the north-west. *Iris aurea* (Lind.) from Cashmere, a plant which resembles and is very likely the same as *I. ochroleuca* of Europe. I have seedlings of two of these, and possibly of another species from Yarkand, but they have not yet flowered.

Of *Polygonatums* we have a large number of species, only one of which, as far as I am aware, is now grown in Europe, viz., *P. oppositifolium* (Wall.), a very fine plant with large clusters of white flowers, streaked red, and succeeded by bright red berries. *Polygonatum Hookeri* (Baker) is a very minute plant, not more than 2 or 3 inches high, but having purple flowers as large, if not larger, than any species of the genus. It is found in the interior of Sikkim at 10,000 to 12,000 feet elevation. *P. cirrhifolium* (Royle) is a curious and pretty species, with small axillary flowers, and narrow leaves, much curled at the tip; it is probably the same as *P. sibiricum*, and is found in the Himalaya from 7,000 to 12,000 feet high, also in China and Siberia. *P. punctatum* (Royle, Bot. Mag. 5061) and *P. roseum* (Bot. Mag.) are, I am afraid, not now in cultivation, though both pretty species.* *P. peristylum* (Baker), from Sikkim, has yellow flowers, but is not so fine a plant as some of the others; and *P. graminifolium* (Hook.), though a very graceful little plant, is not showy. It grows in the north-west at 10,000 to 11,000 feet.

Nearly allied to the *Polygonatums* are the *Smilacinas*, of which there are several sorts. First and finest is *S. oleracea*, a most striking plant, which is found in the temperate region of Sikkim; it grows to a height of 5 or 6 feet, and produces a large terminal panicle of purple flowers. The young shoots of this plant, which somewhat resemble *Asparagus*, are eaten by the natives of Sikkim under the name of *Chokli-bi*, as related by Dr. Hooker, who was himself, during his arduous and adventurous explorations in that country, reduced to eking out his scanty store of provisions with such herbs as he could get. Let me recommend any gardener who has not read this charming and most valuable work—"Hooker's Himalayan Journals"—to take the first opportunity of doing so. It is one of the best and most interesting books I know. Another very pretty *Smilacina*, from Sikkim, is *S. oligophylla* (Baker), a small plant with four *Cypripedium*-like leaves, and a raceme of pink flowers resembling those of *Convallaria majalis*. *S. purpurea* (Wall.), from Kumaon and Nepal, is a pretty plant, in the style of *S. stellata*, but with purple flowers. There is a white variety or species called *pallida*, also from the north-west. In the genus *Flaggea*, which comes near *Smilacina*, we have one or two fine plants, especially *F. Wallichiana* (Kunth), which grows near Darjeeling, at 8,000 feet elevation. It resembles *Ophiopogon* in habit, but has a spike of *Convallaria*-like flowers of a purple colour. The roots are curious, forming many tubers like those of *Apios*

* Wallich's "*Plantæ Asiaticæ Rariores*," Royle's "*Illustrations of Himalayan Plants*," Baker's "*Revision of Tulipæ*," in *Journ. Lin. Soc.*, 1874, p. 211.

* I see a *Polygonatum roseum* in Messrs. Backhouse's catalogue, from Siberia, which may very likely be the same.

tuberosa. *F. dracaenoides* (Baker) is a plant more curious than pretty, the stem of which is covered with sheathing bracts or leaves of a dark purple colour. It is also found near Darjeeling.

H. J. ELWES.

(To be continued.)

THE GARDEN IN THE HOUSE.

DINNER-TABLE DECORATION.

Arrangement of Fruit for Dessert.

In the case of all handsome dessert services, six dishes are generally devoted to fruit, the highest being intended for the top and bottom of the table; and, where additional dishes are wanted for mixing in amongst china stands, none are more suitable than gracefully-shaped glass baskets, oval-shaped glass dishes, which lay flat on the table, and small groups of Parian figures supporting dishes made of the same material. Monotony or sameness in the character of the stands should always be avoided; therefore they should be of different heights and shapes, the tallest being placed, as has just been stated, at the top and bottom of the table. The fruits generally selected for these end stands, when in season, are a Pine and Melon, and they look best resting on a mat formed of Vine leaves, which, in autumn, when a little tinted, have a pretty appearance; and, in addition to the leaves, a wreath of Maiden-hair Fern may be arranged round the base of each fruit. Next in importance are Grapes, which, when Pines and Melons are unattainable, take their place; but, at other times, I like to see them arranged in the glass baskets already referred to. The white and black may be mixed, but if the baskets be small (which look much the best), I like one bunch of each colour in each basket. The baskets should be lined, if possible, with fresh green Vine leaves. Round the handles should be twisted a spray of *Lygodium scandens*, and among the fruit itself should be inserted a few fronds of Maiden-hair and some Vine tendrils. Along with the white Grapes might be put a few tinted leaves of Virginian Creeper, and among the black a few variegated Maple leaves. These also associate well with Plums of the same colours, which look best grouped in flat oval dishes, and may be treated much in the same manner as Grapes; both Plums and Grapes must be carefully handled, or their delicate bloom becomes destroyed, and then much of their beauty is lost. Peaches and Apricots look handsomest in the Parian stands, resting on a mat of bright green Moss, and decorated only with a spray of *Lygodium* twined through them, so as just to tone down their bright colours, but nothing more, their individual beauty being too great to be hid. Strawberries and Cherries also look well in these stands, and should be grouped in the form of pyramids (the stems being turned inwards), with leaves of the latter built up amongst them, the whole being decorated with fronds of Maiden-hair Fern. Greater variety may still be created, if required, by using some of the tropical fruits which are generally on sale in Covent Garden, such as Bananas, Figs, and Dates; Nuts also come in usefully for such purposes. Then there are Apples and Pears, a few handsome fruits of which look well on an oval glass dish decorated tastefully with Ferns, or other foliage of a similar kind. Where fruit dishes are used on the breakfast-table, I like them to be of china, as I think glass there looks out of place. The fruits used for this purpose consisting, as they do mostly, of Strawberries and Currants, should be merely decorated with their own leaves. Where baskets of fruit are employed on the dinner-table, they look best arranged around the centre piece. Stiffness and formality, as regards the position of fruit dishes, should be avoided as much as possible; for instance, a straight line of dishes, running the length of a table, gives it a heavy look. The only fruit which I dislike to see on a table are Oranges; not that I have any dislike to their taste, for nothing is more refreshing on a hot July day, after dinner, than a well kept Orange. It is the colour to which I object, and which does the damage. It kills other fruit, flowers, and even the china, if the latter has any shade of yellow in it; and no amount of foliage seems to tone it down. The only fruit

with which they at all associate well are purple Grapes, and Plums of the same colour. I have found the effect of my table so often spoiled by having Oranges on it, that now, when I want it to look particularly well, I make it a rule not to have them placed amongst other fruits, but handed round with others different from what are already on the table. Many place flowers through their stands of fruit, and in some few cases the mixture looks well; but it will be found a good plan, where this is done, to insert the stems of the flowers in small glass tubes, such as are sold for coat flowers, filled with water—a plan which also answers for keeping the Fern fronds fresh, if required for any lengthened period.

A. HASSARD.

Barrelier's Bell-flower (*Campanula Barrelieri*) as a Window Plant.—I consider this to be one of the finest of all dwarf growing Bell-flowers for window culture, and after trying many other kinds, including *C. pulla*, *C. turbinata*, *C. fragilis*, and others, I have given this the preference. Grown in a pot of rich sandy earth it forms a bushy little plant in the spring, while a month or two later its branches elongate until they hang gracefully over the pot sides covered with pale purplish-blue salver-shaped flowers. One of my plants looks splendidly just now, being a perfect mass of flowers. A good potful of this plant makes a capital substitute for a hanging-basket, and the flowers show to better advantage when the plant is suspended in the window or on the balcony outside. It is also a capital bracket plant, or it looks well on the window-sill, where the shoots can hang down freely. The two best *Campanulas* for the window gardener are, undoubtedly, this and *C. pyramidalis*, which are very distinct from each other in habit of growth, and both perfect in their way.—B.

COTTAGE GARDEN SOCIETIES.

In the following remarks on these societies, which are so useful in spreading a taste for gardening amongst the working classes, I wish to direct special attention to a system that is found to answer admirably here, viz., that of offering prizes for the best kept and cropped gardens and allotments, and for the best specimens of window gardening. These are annually inspected during the summer months, generally in June, and from several years' observation, as one of the judges, I can confidently state that for a very trifling cost a great amount of good may be effected, not only as regards advancing the art of gardening, but in helping those who strive to help themselves. In fact, the competitors are sure of a reward, either in the shape of a prize or in the form of increased production, and, consequently, an increased amount of food for themselves and families. In looking over a number of gardens lately, situated in different parishes, I was agreeably surprised to find the crops in them most luxuriant, and that after one of the most persistent droughts that we have experienced for years. In fact, the difference between garden and field crops, or, in other words, between deep cultivation and shallow, was more marked than I ever remember to have seen it, giving substantial proof that in deep culture and thin seedling lie the chief elements of success. Many of our principal prize winners for Potatoes trench their ground three spades deep, and plant the sets 3 feet apart each way. The gardens, too, were one and all profitably stored with a good stock of plants ready to succeed crops that are early cleared off; and, although many of them are large, scarcely a piece of vacant ground was to be seen in the whole number, as I need scarcely remark that fallow ground is not considered profitable gardening. The allotments do not, as a rule, present much variety, being mostly occupied with root crops for the winter consumption; but all of them are most excellently cultivated. Window gardening was also well represented, considering the means at the disposal of the competitors. Some of the old-fashioned cottages, overhung with sweet-scented climbers and the window aglow with flowers, presented quite a picturesque appearance. The favourite window plants seemed to be *Calceolarias*, *Fuchsias*, *Geraniums*, and a few fine foliaged plants, such as *Tricolor Geraniums* and *Coleus*. As regards the little flower gardens in front of some of the cottages, they, likewise, bore evidence of the effect of example being more powerful than precept. I have often observed, indeed, that in the neighbourhood of large public gardens, or of large private establishments, that, through the liberality of their owners, are open to the public, the system of flower gardening adopted in such places is reflected, as it were, in the smaller gardens around. Therefore, whether in the case of the scarlet and gold of geometrical gardens, or that of mixed borders of herbaceous plants, or the thousand lovely forms of foliage plants, let us at all times be careful to set up such examples as will be worthy of imitation.

JAMES GROOM.

THE FLOWER GARDEN.

AN ORNAMENTAL MINIATURE GOURD.

(BRYANOPSIS LACINIOSA.)

THE pretty illustration of the Gooseberry Gourd, in the first number of the present volume of THE GARDEN (see p. 3), has induced me to bring under the notice of your readers another

pretty variety of that interesting family of plants. The plant from which the accompanying sketch was taken was raised from seeds brought from Africa last year by Sir Samuel Baker, and presented by him to my employer last winter. It is, therefore, looked upon as a sort of souvenir from a comparatively unknown land. Sir S. Baker informed me that, in its wild state, this variety covers dwarf trees and shrubs with its slender climbing shoots, which are loaded at every joint with pretty little fruits, which, in a young state, are bright green, striped and spotted with white, but which, when ripe, change to scarlet, a colour which sets off the white spots and pencillings to increased advantage. The fruits, as will be seen, are borne in clusters of from three to four together. The foliage, being of a distinct shade of green, renders the plant effective, even when not in fruit. It has been growing in our Melon-house, in which it quickly covered a large trellis, and is loaded with fruits which, were it not for their white marblings, might easily be mistaken for those of *Solanum Capsicastrum*. I was told that some of the African tribes use the long slender shoots of this Gourd for garlands and head dresses, purposes for which its habit of growth eminently fits it. Long festoons of it, laden with fruit, might be usefully employed for garnishing our desserts and for twining round stems of March stands on the dinner-table, or the sprays of crimson fruit might be allowed to hang naturally and gracefully from the margins of ornamental vases. Gourds of this description well deserve more attention than they have hitherto had.

JAMES GROOM, Gardener to Earl Stradbroke,
Henham Hall, Wanganford.

INDIAN GARLAND FLOWER.

(HEDYCHUM GARDNERIANUM).

This truly beautiful and Oriental flowering plant, was introduced into our gardens as far back as the year 1819, and, being a native of the East Indies, has generally been considered and treated as a stove-plant, where it grows and flowers profusely. During 1868, I first saw this species cultivated and freely flowered (under cool treatment), in the conservatory belonging

to William Craven, Esq., of Brunnington House, Corstorphine, near Edinburgh, in which it is kept all the year round. I was not aware till I saw it at Brunnington House, that it could be so treated. It is frequently grown in warm-houses and removed to the greenhouse or conservatory during the flowering period, and when past, again returned to warm quarters, and is now very generally seen in many of the cool conservatories and greenhouses around Edinburgh, where it presents rather a tropical appearance amongst the ordinary greenhouse plants. Having ascertained that it thrives so well in a cool greenhouse, I planted some strong roots in the open border during the spring of 1873, where they grew well but did not produce flower-spikes. Late in autumn the surface of the ground over the roots was covered with some stable litter, which was afterwards dug in. During the spring of 1874, numerous stems were produced, but none of them strong enough to carry flower-heads, evidently from the want of climate, but I have great hopes that it will succeed when planted at the base of a wall with a south aspect, where it is but natural to suppose that the growth should be nearly as well

Fruit-bearing sprays of *Bryanopsis laciniosa*.

matured as in a cool conservatory. In the climate of London it ought to produce flowers in many gardens under border-cultivation, particularly in the so-called sub-tropical ones. If it is cultivated in the open air round London, which I have not been fortunate enough to observe, it is certainly not to such an extent as it is justly entitled to from its stately appearance. As soon as the blooming is over in the conservatory, the early flower-stems ought to be cut down, so as to strengthen the later-blooming ones. A few of the un-

flowered stems may safely remain on throughout the winter, and, if strong enough, will bloom early. During spring the plants can be re-potted, and, if necessary, divided, as the rhizome or surface roots are capable of being separated into numerous plants. If specimens are wanted to flower early, the pots or tub containing them should be placed in flats of water, some may be put in the conservatory, and treated in the ordinary way without water flats, some could be put in heat, while others, after their flower-stems are matured, can be placed in sheltered situations in the open air and taken in when required; by these various means, a succession of flowering plants may be obtained during eight or nine months in the year. The *Hedychiums* thrive well when planted in soil mixed with a little old manure and sand, while, liquid manure, occasionally applied during the growing season, will strengthen the plants and increase the richness of the flower-spikes. Plants in pots or tubs about 14 or 15 inches in diameter, frequently have from eight to ten blooming heads at one time, while larger pots or tubs may have double that number; many of the heads being 14 inches long and 18 inches in circumference; a succession of flower-spikes is often got on the same plant. For exhibition or competition purposes, flowering *Hedychiums* would prove most interesting subjects. Numerous species are now in cultivation, in colours red, yellow, orange, and white. It is, therefore, quite possible to conceive, that in the hands of a skilful hybridiser, a series of crosses may be produced, which, some day or other, may prove interesting objects for the conservatory.

JAMES McNAB.

THE FRENCH MARIGOLD.

"HANDSOME, but unsavoury," is the character truth compels me to give to the French Marigold. Still, its peculiarity of perfume is not discernable until it is handled, and, perchance, that should be to many gardeners a good reason why they should largely use this flower to decorate their borders, as nothing can be more annoying than to see the members of the household traversing the flower-borders and beds, day after day, with basket and shears, and sweeping off all that is gay and beautiful amongst the flowers. But this Marigold has other claims than this upon our notice. As a decorative plant it is one of the most effective of all tender annuals, and none gives such a continuity of bloom; as, did not the frosts interfere, it seems doubtful whether it would ever die, and certainly as long as there was life there would be flowers. Our knowledge of the French Marigold has hitherto been chiefly linked with a tall branching and straggling habit of growth, and flowers of medium size and indifferent quality, and chiefly dark-coloured. In the south the French Marigold has rarely, if ever, been elevated into the position of an exhibition flower, and in this respect, there has been but little stimulus given to its improvement. In the northern portions of the kingdom, however, it is much cultivated for show purposes, but the striped flowers are only favoured, and as these have generally been found on the strongest-growing plants, there has been no inducement to improve the habit of the plant for border or bedding purposes. Two things, however, have assisted to promote that object, quietly, but surely; first, the failure of the yellow *Calceolaria* as a bedding plant; and, second, the introduction from the Continent of single and double forms of the *Tagetes*, which drew attention towards the French Marigold as a proper substitute. It may be that a dwarfer habit of growth sported out from the taller kinds, naturally, but it is certain that several years since, when I took these Marigolds in hand, I selected some that displayed a more compact form of growth, and these were lifted from the others and set aside to seed, without being impregnated with the pollen of the tall kinds. Thus, in a few years a distinct dwarf compact-growing strain was obtained, having flowers of good quality and of several hues of colour. From among these again I commenced to select colours that would make effective bedding varieties, securing first the form known as *Anrea floribunda*, which received a first-class certificate at South Kensington, and which promises to make the best yellow summer bedding plant in cultivation. Its habit is exceedingly dwarf and compact, being, when in full bloom, about 10 inches in height, and covering a square foot of ground. The flowers are very double, of good size, golden-yellow in colour, and borne most profusely. Allied to this is another selection that is just a trifle taller in growth, the flowers being equally double, but of a rich orange. And still another selection has an exactly duplicate habit and quality of bloom, the flowers being chestnut and edged with gold. Either of these varieties will make

very effective beds, and when once established, are quite independent of climate, flowering freely whether it be hot or cold, wet or dry. As I grow a large quantity of these Marigolds, I simply transfer them from the seed bed to the open ground, dibbling them in about 12 inches apart, but, if used for bedding and treated in this way, it would be well to have some plants in reserve potted off singly, as in the finest strain there will always be some flowers that would be better out, and, with plants in reserve, the vacancies are soon filled up. It is a curious fact in relation to these dwarf kinds, that while some of the plants produce semi-double flowers, none of them produce single ones. In the finest of the tall strains some single flowers will always result. In addition to these selected bedding forms, I am trying to secure on the dwarf habit of growth, not only good shaped flowers, but also some of increased size, and am this year rewarded by having some self-coloured blooms on plants 12 inches in height, as large as are the best flowers of the lemon-coloured African Marigold. Striped flowers are also showing profusely on plants 9 and 10 inches in height; and I am hopeful that, in a very few years, the tall branching kinds may here be looked on as things of the past. During the past week or two the wind has been blowing with great force, and now and then a large branch of the tall kind is twisted off with ease; the dwarf kinds are, however, quite uninjured, as they are so stiff and strong that the wind exercises no injurious influence over them. The mixed strain comprises striped, yellow, orange, chestnut, brown, and many varicoloured flowers, and furnishes most admirable plants for border decoration. Seed should be sown, in boxes or pans, at the end of March; and, if placed on the shelf of a cool house or in a frame, will speedily germinate. When the plants are 3 inches in height, it will be better for them to be pricked out from 2 to 3 inches apart in a cool frame, giving plenty of air, and then they will plant out safely, and with nice balls of earth attached, as soon as all danger from frost is over; and, as I have before mentioned, if a few plants of the bedding kinds be kept in reserve, then the beds may be filled to the best advantage, and all the flowers prove of the best quality and true to colour.

ALEX. DEAN.

Bedfont.

CENTAUREA RAGUSINA.

For toning down glaring colours, nothing could possibly be finer than this. Solitary plants of it placed in the centres of small circles, and surrounded with any bright colour, look grand. Long lines of it, backed and fronted with any dark-foliaged plant or glowing flowers, give a very pleasing and harmonious relief. Where large ground-works of scarlet, purple, or blue are made, an elevated plant of this, placed here and there, break up the monotony which would otherwise exist, and enhances the appearance of the outlying colours in a very marked degree. Wherever any vivid or intense colour appears, this plant should never be far from it. The pale silvery foliage of isolated plants judiciously dotted on lawns on the bright green Grass, and amongst dwarf dusky-leaved shrubs, has also a good effect. When used for this purpose, the plants may either be planted out or plunged in their pots, as many of the sub-tropicals are. It is never injured by wet, and its robust compact-growing habit prevents the wind from having any tarnishing influence on it. It thrives in the coldest situations throughout the summer. The propagating of *Centaurea ragusina* is a matter often attended with very indifferent results. It is, however, as easily, and may be as successfully, rooted as *Zonal Pelargoniums*. When taking cuttings from the old plant, they should not be cut away; but pulled off with a heel, so that they may have a hard base. The small firm shoots should be chosen in preference to large soft ones. In making, the knife should be used as little as possible. Each cutting should be put singly into a small thumb-pot filled with a mixture of loam, leaf-mould, and sand, and set in a cold frame. One good watering is sufficient until they are rooted; and, if the weather is excessively damp, the lights may be drawn over them, and tilted up in back and front; otherwise, they may remain fully exposed. Treated in this manner, I have rooted a batch of 2,000, without losing twenty out of the lot. Autumn is the best time to propagate them. They will fill their pots with roots in three weeks; and, if plenty of wintering accommodation exists, they make all the better plants by being shifted into 4-inch pots, where they will grow a little this autumn, and make nice strong material for bedding out next year. A cold frame, from which frost can be excluded, is a suitable place for their winter quarters. The leaves should be kept dry, as they are rather liable to damp during the short days. Every favourable opportunity should be embraced for liberal air-giving; they also winter well in an airy Vinery or greenhouse. Old plants are sometimes lifted and kept over the winter. Where large plants are required, this is a sure means of obtaining them; but, for ordinary bedding purposes, autumn-struck cuttings are the best.

J. MUIR.

BEARDED IRIS (I. BARBATA), COMMONLY CALLED GERMAN IRIS.

My collection of this section of *Iris* has been pronounced to be very complete. It numbers upwards of 200 varieties, from which I have selected those enumerated. The better to understand my descriptions, I furnish a wood-cut, by which it will be observed that one half of the petals are erect—these are called standards; the other half droop—these are called falls, while the small tongued parts of the flower are called petioloid stigmas, under which run the “beards.” The flowers in this section are all large and handsome, and more or less beautifully mottled in the standards and reticulated in the falls, the beards ranging from delicate primrose to orange, and the petioloid stigmas frequently materially enhancing the general effect by colour and contrast. I mention this, as in my descriptions I have not attempted to take in all these points, but deal with the colours which strike the eye on first looking at the flower. There is no flower, however, that so improves by examination. At first sight its beauty is equal to that of an *Oreoid*, but, on closer examination, I have no hesitation in saying it possesses points of interest surpassing those of the finest epiphyte. In colours there are the richest yellows, the intensest purples, the most delicate blues, the softest mauves, and the most beautiful claret-reds. There are whites and primroses, and bronzes of every imaginable shade; indeed, language fails

Iris iberica.

to picture the beauties of this flower; and, consequently, my descriptions fall far short of the reality. And this will be readily understood when I state that there may be found in almost any one of the flowers from ten to thirty different shades, all harmonising and blending in the most perfect manner imaginable. Those who have not used this *Iris* for surrounding artificial lakes and ponds, or for growth in the flower borders, shrubberies, and woodland walks, should do so; for, wherever a large quantity of out flowers is required from May to July, these plants, when established, will yield them bountifully; as, with good cultivation, they increase in size annually till they attain large proportions, each plant yielding from fifty to a hundred spikes of bloom.

- I. germanica** (*Reich.*).—Standards, blue; falls, purple.
 „ *violacea*.—Standards, purple; falls, dark purple.
 „ *alba* (*Florentina*).—Standards and falls, white.

The above are the first of the *barbata* section to flower, and, being distinct from each other in colour, and flowering at the same time, produce a fine effect early in May, and furnish a striking contrast. The following species and varieties come into flower as the above are going out of bloom; and it may be worthy of notice that *Aphylla* embraces the species *plicata* and *Swertii*, and the section is remarkable for the flowers having a frill-like appearance—an effect arising from the multitude of coloured transverse lines running round the margin of the standards.

- Forms of I. aphylla** (*Bot. Mag.*).—Standards, creamy white, margined with dull lilac; falls, white, margined with lilac.
 „ *Beauty*.—Standards, white, margined with lilac; falls, white, the upper part reddish-lilac.
 „ *Bridesmaid*.—Standards, very pale lavender; falls, white, margined with lavender.
 „ *coelestina*.—Standards, lavender-blue, mottled with deeper lavender; falls, white, margined with lavender-blue.
 „ *Gazella*.—Standards, red-lavender, mottled with white; falls, white, edged with purple.
 „ *Madame Chereau*.—Standards, white, margined with blue; falls, white, margined with blue.
 „ *striata*.—Standards, white, margined with lavender; falls, white and lavender.
I. amoena (*Sweet*).—Standards, white, tinged with lavender; falls, white, slightly margined with lilac.
 „ *Alise Barr*.—Standards, white; falls, white, tinged with lilac.
 „ *Ariadne*.—Standards, white, mottled with purple; falls, crimson, reticulated with white.
 „ *Alvarez*.—Standards, white, mottled with purple; falls, crimson, reticulated with white.
 „ *Calypso*.—Standards, white; falls, mottled with purple and white.
 „ *Comte de St. Clair*.—Standards, white; falls, crimson-purple, reticulated with white.
 „ *Clio*.—Standards, white; falls, crimson-purple.
 „ *Donna Maria*.—Standards, white; falls, white, tinged with lilac.
 „ *Duchess de Nemours*.—Standards, white; falls, purple, mottled with white.
 „ *Duchess d'Orleans*.—Standards, white; falls, crimson-purple, mottled with white.
 „ *Glorietta*.—Standards, white, slightly tinged with lilac; falls, white, heavily tinged with crimson.
 „ *Incomparable*.—Standards, pure white; falls, crimson-purple, reticulated with white.
 „ *Juliette*.—Standards, white, tinged with lavender; falls, violet-blue, tinged with white.
 „ *Morphens*.—Standards, white, tinged with lavender; falls, violet, heavily mottled with white.
 „ *Poitain*.—Standards, white, tinged with lavender; falls, very rich velvety-crimson.
 „ *reticulata alba*.—Standards, white; falls, purple-crimson, reticulated with white.
 „ *Sir Garnet Wolseley*.—Standards, pure white, slightly margined or flaked with purple; falls, velvety-crimson, very heavily reticulated with white.
 „ *Unique*.—Standards, white; falls, violet-purple, reticulated with white.
 „ *Unique Surpassed*.—Standards, white, tinged with lavender; falls, deep crimson, edged and reticulated with white.
I. neglecta (*Bot. Mag.*).—Standards, lavender; falls, upper part red-lilac.
 „ *Agathe*.—Standards, white, margined and mottled with lavender; falls, white, margined with lavender.
 „ *Alice*.—Standards, pale lavender; falls, rich purple, mottled with white.
 „ *Alonzo*.—Standards, lavender; falls, purple-crimson.
 „ *amabilis*.—Standards, lavender-purple; falls, rich deep crimson.
 „ *Aspasia*.—Standards, white; falls, purple-crimson, mottled with white.
 „ *Aspasia Variety*.—Standards, white; falls, dark purplish crimson, mottled with white.
 „ *Atropos*.—Standards, lavender-blue; falls, rich velvety crimson, upper part mottled with white.
 „ *atro-purpurea*.—Standards, deep purple; falls, very deep purple.
 „ *Bocaze*.—Standards, decided lavender; falls, purple, mottled with dark lines.
 „ *Cameleon*.—Standards, rich blue; falls, light crimson.
 „ *Clara*.—Standards, lavender; falls, rich purple-crimson, reticulated with white.
 „ *Clarissima*.—Standards, purple, shading to blue; falls, rich crimson, mottled with white.
 „ *Cleopatra*.—Standards, light lavender; falls, velvety purple-crimson, reticulated with white.
 „ *De Bois de Milan*.—Standards, light lavender; falls, rich crimson.
 „ *Fairy Queen*.—Standards, white, flaked with purple-blue; falls, purple-blue, heavily reticulated with white.
 „ *Fantasie*.—Standards, lavender-blue; falls, purple, mottled with dark lines.
 „ *Florence Barr*.—Standards and falls, delicate lavender.
 „ *halophylla*.—Standards, lavender-blue; falls, red-lavender.
 „ *Harlequin Milanais*.—Standards, white, tinged with lavender; falls, rich crimson-purple.
 „ *Indigo*.—Standards, purple; falls, deep velvety purple.
 „ *Irma*.—Standards, lavender; falls, crimson-purple, heavily mottled with white.
 „ *Monsieur de Seble*.—Standards, deep lavender-blue; falls, lavender-purple.

- I. neglecta.**—Nationale.—Standards, purple-blue; falls, rich velvety crimson.
- „ Penelope.—Standards, white, variegated with lavender; falls, white and lilac, reticulated.
- „ purpurea.—Standards, purple; falls, dark purple.
- „ reticulata.—Standards, pale lavender; falls, rich velvety crimson, reticulated with white.
- „ Rowlandiana.—Standards, lavender-blue; falls, light purple, upper part reticulated with white.
- „ ruberrima.—Standards, red-purple; falls, claret.
- „ Sultan.—Standards, lavender-blue; falls, very rich velvety crimson-black.
- „ Tatie Barr.—Standards, lavender-primrose; falls, pale purple.
- „ Victorine.—Standards, white, mottled with blue; falls, rich violet-blue, upper part mottled with white.
- „ Virginie.—Standards, lavender; falls, rich velvety crimson, lined with white.
- I. pallida** (*Reich.*).—Standards, dark lavender, passing to light lavender; falls, purple, passing to light purple.
- „ Assaurez.—Standards, rich red-purple; falls, claret.
- „ Astarte.—Standards, purple-lilac; falls, rich crimson-purple.
- „ azorea.—Standards, azure-blue; falls, violet-blue.
- „ Balmatica.—Standards, lavender-blue; falls, lavender, tinged with purple.
- „ Duke of York.—Standards, light claret; falls, dark claret.
- „ Garibaldi.—Standards, rose-lilac; falls, rose-purple.
- „ Maerisart.—Standards, mauve; falls, purple-crimson.
- „ Madame Pacquette.—Standards, rich claret-red; falls a deeper shade of claret-red.
- „ Queen of May.—Standards and falls, rose-lilac.
- „ Raphael.—Standards and falls, deep lavender-blue.
- „ Rowlandiana purpurea.—Standards, deep lavender; falls, purple.
- „ rubella.—Standards, red-purple; falls, deep red-purple.
- „ speciosa.—Standards, red purple; falls, rich crimson-purple.
- „ variabilis.—Standards, light purple; falls, deep purple, both fading off to slate-lavender.
- „ Walner.—Standards, deep lavender-blue; falls, purple, mottled with white.
- I. squalens** (*Reich.*).—Standards, primrose-bronze; falls, crimson-purple, reticulated with white.
- „ Arnols.—Standards, bronze-purple; falls, rich velvety crimson.
- „ Bossuet.—Standards, sulphur-bronze; falls, crimson, heavily reticulated with white.
- „ Cerbere.—Standards, lavender-bronze; falls, crimson-purple, reticulated with white.
- „ Dr. Bernice.—Standards, coppery-bronze; falls, very rich velvety crimson.
- „ Folgerie.—Standards, yellow-bronze; falls, crimson-brown, reticulated with white.
- „ Hericart de Thury.—Standards, bronze-primrose; falls, red-brown, reticulated with white.
- „ Hugh Block.—Standards, primrose-bronze; falls, reticulated with light purple, white and brown.
- „ Iearn.—Standards, primrose-bronze; falls, purple-crimson, reticulated with white.
- „ Innocenza.—Standards, blue-lavender, tinged with primrose; falls, decided lavender.
- „ Judith.—Standards, bronze-primrose; falls, dark crimson-purple, reticulated with white.
- „ Julius Cesar.—Standards, yellow-bronze; falls, rich velvety-crimson.
- „ Lady Jaue.—Standards, brown-bronze; falls, crimson-bronze.
- „ Lady Seymour.—Standards, lavender; falls, white and purple mottled.
- „ Lady Stanhope.—Standards, bronze-primrose; falls, rich velvety crimson, narrowly margined with yellow and reticulated with white.
- „ La Prestiose.—Standards, glittering bronze; falls, rich velvety-crimson, reticulated with white.
- „ latifolia.—Standards, primrose-bronze; falls, purple, mottled with white.
- „ lavendulacea.—Standards, lavender, tinged with primrose; falls, decided lavender.
- „ La Vesuve.—Standards, blue, mottled with bronze; falls, rich purple-crimson.
- „ Lord Grey.—Standards, coppery rose; falls, deeper coppery rose.
- „ Monsieur Cherion.—Standards, sulphur-bronze; falls, crimson-velvet, mottled with white.
- „ Monsieur Fries.—Standards, primrose-bronze; falls, light purple.
- „ Mozart.—Standards, brown-bronze; falls, purple-bronze and white mottled.
- „ Mrs. Weston.—Standards, bronze-purple; falls, rich purple.
- „ Pancratius.—Standards, primrose-bronze; falls, pale purple.
- „ Phydias.—Standards, brown-bronze; falls, rich deep crimson.
- „ Racine.—Standards, light bronze-purple; falls, rich purple.
- „ Rebecca.—Standards, primrose-bronze; falls, intense crimson.
- „ Rigolotte.—Standards, bronze-yellow; falls, crimson, reticulated with white.
- „ Solomon.—Standards, brown-bronze; falls, rich crimson, heavily reticulated.
- „ Van Geertii.—Standards, purple-bronze; falls, rich crimson, reticulated with white.

- I. squalens.**—venusta.—Standards, bronze-primrose; falls, rich crimson, reticulated with white.
- „ Walneriana.—Standards, bronze-purple; falls, purple, upper part reticulated white and bronze.
- „ Walter Scott.—Standards, bronze-yellow; falls, rich brown-crimson.
- I. variegata** (*Bot. Mag.*).—Standards, rich yellow; falls, rich crimson-brown.
- „ Abon Hassan.—Standards, fine clear rich yellow; falls, yellow, mottled with crimson-brown.
- „ Adonis.—Standards, chrome-yellow; falls, crimson-brown, reticulated with white.
- „ Alcibiades.—Standards, yellow; falls, velvety crimson.
- „ angustissimus.—Standards, rich golden yellow; falls, velvety crimson-brown.
- „ Bergiana.—Standards, rich yellow; falls, very rich crimson-brown.
- „ Chelles.—Standards, rich yellow; falls, crimson-brown, heavily reticulated with white and yellow.
- „ Czarowitch.—Standards, fine chrome-yellow; falls, crimson-purple.
- „ De Bergii.—Standards, sulphur-bronze; falls, velvety crimson, mottled with white.
- „ Dr. Bersine.—Standards, chrome-yellow; falls, white and crimson mottled.
- „ Honourable.—Standards, deep yellow; falls, crimson-brown, reticulated with yellow.
- „ Humboldtii.—Standards, yellow; falls, velvety crimson-brown.
- „ Louis de Cerise.—Standards, light yellow; falls, crimson-purple, reticulated with yellow and white.
- „ major.—Standards, rich deep yellow; falls, crimson-brown, reticulated with white.
- „ Malvina.—Standards, yellow, tinged with bronze; falls, brown and white, mottled.
- „ Mexicana.—Standards, fine chrome-yellow; falls, crimson, reticulated with white.
- „ Mimico.—Standards, rich yellow; falls, rich crimson-brown.
- „ Minnie.—Standards, orange-yellow; falls, crimson-brown, reticulated with white.
- „ multicolor.—Standards, rich deep yellow; falls, crimson-brown, mottled with yellow.
- „ Orphee.—Standards, rich yellow; falls, white and crimson reticulated.
- „ Prince of Orange.—Standards, orange; falls, crimson-brown, mottled with white.
- „ Samson.—Standards, yellow; falls, crimson, mottled with white.
- „ Sans Souci.—Standards, orange-yellow, falls, crimson, reticulated with yellow and white.
- „ spectabilis.—Standards, yellow; falls, rich velvety crimson.
- I. aurea** (*Rob. Regel*).—Standards and falls, rich yellow.
- I. flavescens** (*Sweet*).—Standards, primrose; falls, light primrose.
- „ Munite.—Standards, primrose; falls, primrose, reticulated with lavender.
- I. florentina** (*Reich.*).—Standards, white; falls, white.
- I. lurida** (*Reich.*).—Standards, bronze-purple; falls, rich purple-crimson, richly scented like elder.
- I. subiflora** (*Bot. Mag.*).—Standards and falls, very rich deep purple.
- I. sambucina** (*Bot. Mag.*).—Standards, lilac-bronze; falls, rich purple-crimson, richly-scented elder.
- „ major.—Differing from the above in height. PETER BARR.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Japanese Primroses (*P. japonica*).—My Japanese Primroses, which have been so fine this year (see p. 16), are all in the open air, and much admired they have been.—ANNIE OWEN.

Evening Primroses (*Oenotheras*).—These have been very fine with me this season. *O. amoebola* is more than 2 feet high, and flowering profusely; the blossoms are nearly 5 inches across. Of the white flowering prostrate kinds, *varaxifolia* and *eximia* are the best, and the latter has the advantage of being perfectly hardy. *Marginata*, though very distinct, is poor compared with either of these. Of the large yellow-flowered kinds, *missouriensis* is excellent and quite hardy. *Lumarekiana* is a fine (annual) species which sows itself freely, but it is too large for small beds.—J. WHITTAKER.

Bedding Geraniums.—Dr. Denny and myself are anxious to get up some good prizes, open to everyone, for bedding Geraniums, subject only to the condition that the raiser's name be attached to each plant. Will any of my friends assist us? Any contributions to this object will be gladly received by me, and the names will be published in the papers. We are each prepared to give five guineas, and any assistance will be welcome. Our object is to gather together all the best varieties in the country, so that all may have an opportunity of seeing which are the best worth cultivation.—J. K. PEARSON, *Chilwell*.

Fuchsias in Ireland.—A correspondent of one of the daily papers speaks of the astounding luxuriance of the old red Fuchsia in Ireland, near Carlingford Bay. It assumes the proportions of trees, mounts above the eaves and chimneys, and shades the windows with big clustering sprays of tiny dark green leaves and deep scarlet waxen bells. Many of these shrubs must be of patriarchal age, for their trunks are gnarled and tough as Oak; but the older they are the more determined is their perseverance in showing around an exhaustless wealth of hardy grace and colour. In one or two instances the dwellings were completely hidden and turned into bowers by this quantity beautiful plant or tree. This sight may be seen at or near the village of Dunavon.

THE INDOOR GARDEN.

HYMENOCALYX UNDULATA.

THE genus *Hymenocalyx* was founded by Herbert, who separated it from the genus *Pancratium* of Linnaeus. The species which forms the subject of this note (*H. undulata*, Herb., *Pancratium typhyllum*, Willd.) is a native of Caracas, New Granada, and is one of the handsomest stove-plants in cultivation. From an elongated bulb it sends up a stout compressed scape or flower-stalk, about 1½ feet high, terminated by an umbel-shaped inflorescence, at the base of which are numerous scarious bracts of a greenish-white colour. The flowers are tubular, very fragrant, about 6 inches long, pure white, slightly greenish at the ends of the petals, which are five in number, linear in shape, reflexed and twisted, and from 3 to 4 inches long. In the centre of each flower is a shallow cup, from which issue six long stamens. The leaves are radical, persistent, stalked, oval-elliptical in shape, and a foot or more in length; leaf-stalks, winged, and sheathing the flower-stem. This very striking plant, the habit of which is well shown in our illustration, deserves more attention than it appears to

*Hymenocalyx undulata*.

receive at present. It is easily multiplied by separation of the young bulbs, which should be taken from strong plants, after they have done flowering. It may also be multiplied by means of the suckers which the plant frequently produces. W. M.

NEW TUBEROUS ROOTED BEGONIAS.

A FEW years ago Messrs Veitch & Sons, introduced to our gardens three or four species of *Begonia*, distinct in character and very beautiful; and when it was found that they, or at least one or two of them, were hardy enough to stand considerable exposure without harm, their value was materially increased. One was *Begonia boliviensis*, a bulbous-rooted type, from Bolivia; the foliage light green and the flower bright glossy red, very freely produced, generally in pairs, but sometimes in whorls of three. *B. Pearcei* has much distinctness of character, having handsomely shaded light olive-green leaves, and large bright yellow flowers, produced singly, and occasionally in pairs. *B. Veitchii* was found near Carzo, in Peru, and it has immense blooms of a vivid vermilion or cinnabar red; and, having been discovered at an elevation of upwards of 12,000 feet, it has proved in this country sufficiently hardy to stand the winter without injury. These imported forms were found to seed freely, and by cross-

ing them a progeny has resulted, partaking of the characters of all the foregoing, and so good as to demand the attention of all lovers of flowers. The blossoms are of all shades of scarlet, from yellow to carmine, and from pink to crimson. They are not in the hands of one or two men only, for, as usually happens, many have tried their hands at cross breeding; and batches of new *Begonias* are as common as new bedding *Geraniums*, *Dahlias*, &c. Some of the earlier hybrids were *Chelsoni*, *Intermedia*, *Sedeni*; and then from these have sprung a very large progeny. If I were disposed to recommend a few, in order to lay the foundation of a collection, I should name *Carminata*, *Carnea splendens*, *Dr. Masters*, *Brilliant*, *Dazzle*, *Rosea alba*, *Gem*, *Giltter*, *Lothair*, *Mazeppa*, *Meteor*, *Surprise*, and *Trojan*. When the plants have done blooming, and the foliage decays—for this race of *Begonias* are all of a deciduous character—the plants should be allowed to dry off; the soil should be shaken from the roots, and these should be put away to winter in a dry place, as one would *Dahlias*. In early spring they can be potted and grown on for the summer display. It will thus be seen that their cultivation is within the reach of anyone having a fitting place to flower them in; and there is reason to believe that, like *Begonia Weltoniensis*, many of them will make most acceptable window plants. R. D.

Plants for Screens.—What plants are best to use for a wicker screen, in front of which is a long trough for flowers, about a foot and a half deep? I want it to look bright and gay all the winter. —K. B. [Nothing makes a screen so good and pleasing as the common Irish Ivy. Besides its great lasting properties, it may be tampered with at the roots more than anything else will stand. If the trough of the screen is wide enough at the time the Ivy is planted, place in the soil, in front of the Ivy plants, a row of empty pots, so that you can introduce any sort of variegation you like by changing the empty pots for the full ones, or flowers may be used; but, as you will see, the pots give a chance of more variety all the year round. Some of our screens are only 1 foot wide in the trough, yet they are in beautiful order after a service of twenty years, although a row of 32-sized pots takes up so much of the Ivy's root space.—J. FLEMING, *Cliveden*.]

Palms for Market.—Palms always command a sale and realise good prices, being, as they are, alike suitable for the decoration of halls, windows, or the dinner-table. Foremost amongst market Palms is the *Livistona borbonica*, a kind which is raised from seed in large quantities, and which is in good saleable condition at two, three, and four years old. *L. altissima* is certainly in greater demand than *L. borbonica*; but it is seldom to be met with in the market on account of the difficulty experienced in obtaining seeds of it from which to raise young plants in quantity. *Rhapis flabelliformis* is another good market Palm, and, when grown to the height of 2 or 3 feet, it has a graceful tree-like appearance. Like the last, it is always scarce and dear on account of the difficulty experienced in getting seeds of it. Such plants of it as make their appearance are usually the produce of offsets or suckers. The *Rhapis*, when sent to market, has never more than one stem, but, if necessary, it might be grown so as to have scores of stems like the specimens of it in the Palm stove at Kew. *Corypha australis* is another common market Palm, and also a desirable sort on account of its hardy constitution, as well as its neat appearance.—Q.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Dolichodeira (Gloxinia) tubiflora.—This is a useful decorative plant when grown in small pots and flowered in a young state. It has oblong crenate, rather hairy, leaves, and bears pure white flowers on stems from 12 to 18 inches in height. The individual flowers are 4 or 5 inches long, and last a long time in perfection. It grows well in a moderately warm greenhouse or plant stove, and is readily propagated, with ordinary care and attention, either by means of cuttings or seeds.—B.

Fine-leaved Plants for Cool Greenhouses.—I should be obliged to you, or any of your readers, for a list of plants with fine foliage or habit which will grow in a greenhouse.—S. G. [*Aralia Sieboldi*, *Dracaena australis*, *D. indivisa congesta-rubra*, *Araucaria excelsa*, *A. columnaris*; the *Fan*, *Date*, and *Chusan Palms*; common *Maize*, *Rhapis flabelliformis*, *Musa superba*, *Cannas*, many fine *Solanums*, *Passion-pagets*, *Ficus elastica* and others; *Phoradendron tenax*, *P. Cookii*, *Yucca aloifolia*, *Y. filamentosa*, and *Y. filifera*.—Ed.]

Goodyera Dawsonii.—It may interest some of your readers to know that this plant will make a vigorous growth in a cool humid shady greenhouse during the summer months. In habit and flowers it resembles *G. discolor*, but the leaves are lined with bronze-coloured streaks, and are of a fresher green. I recently saw a fine plant of it growing under the above conditions in Mr. Ley's nursery at Croydon, and it was in the most luxuriant health, notwithstanding that the plant had had repeated overhauls at the hands of that merciless operator—the propagator.—B.

THE SHAKESPEAREAN GARDEN.

THE celebrity of several of Shakespeare's plants dates from the earliest ages of literature; the sweet and immortal fame of others began with himself. To the latter class belong the Cowslip and the Daffodil, the Harebell, Hawthorn, and the Pansy; Lavender also, Ferns, Furze, and many besides. To the former, or the ancient, belong the Rose, the Lily, the Violet, and the Poppy; among trees, the Pine and the Oak, the Cedar, the Cypress, and the Willow; and of miscellanea, Reeds, Sedges, Darnel, Briars, Rosemary, &c. Of course these lists are not exhaustive, but they will serve to indicate under what very different associations the history of the several plants has to be contemplated. That the plants allow of being thus marshalled is a fact very important to notice, since many of the names commonly employed in classical verse became in subsequent ages stereotyped metaphors with mere rhymesters. The plants and flowers in question came to be cited much in the same way as the pearl and the emerald, the deserts of Africa, and similar phrases. Sometimes, no doubt, they were spoken of from personal knowledge—far more frequently, it is quite certain, they were cited only at second-hand, on the strength of the reputation already acquired. The mention of the Rose may be assumed, perhaps, to have been always or usually genuine, this flower having been so generally cultivated; so, probably, may be regarded the mention of the Oak, at all events by English authors. But I very much doubt if with the great mass of the writers who have introduced the Lily into their verses, there has been one in a hundred who has known more than that it is a kind of beautiful white flower, proper, and orthodox, and poetical, to praise, and to use as an image of the fair and queenly. Whether it has three petals or four, whether it blooms in May or September, whether it grows singly or in clusters, would be questions that very few could answer correctly, if at all; those who are most prone to employ such terms are very generally the most deficient in practical knowledge of the things themselves. Shakespeare, on the contrary, scarcely ever used an old-established botanical simile without proving to us, at the same moment, that he knew the plant; with him, therefore, the simile was essentially, and to all practical ends, original. Authors in general are distinguished by casting their light sideways. In Shakespeare we get not only the sideways, but there shines upon us at all times that strong and unmistakable vertical light which declares the master; one who speaks with authority, and not as the scribes. While, moreover, he shows us, by the way in which, for his own part, he introduces the Rose and the Lily, the Oak and the Pine, that, although employing the ancient images, he has found them for himself; he vindicates his independence of the authors who had gone before by adverting to things they never mention, and in the same consummate manner. It is this last which gives energy to his allusions. Many an author mentions a thing for the first time, but for it to step forth like one of the goddesses in Homer is quite another matter. Shakespeare was not only no copyist of the old-accustomed imagery, or such as had been employed by Ovid and Virgil; but, through possessing so much eyesight of his own, so much of that sweet aptitude to observe for one's self, which is better than any amount of mere capacity for echo and reverberation, however timely, he perceived everything that *they* saw, and along with it a great deal more. With *him* blossom the Cuckoo-flower, long Purples, the Crown Imperial; he talks of burnet and of pig-nuts, the common things of the world, which, along with its *bijouterie*, are, after all, the least familiar to people in general; for seeing is, in reality, one of the fine arts; the principles may come by Nature with most or all of us, but it is only here and there that seeing is really exercised. Had his attention been specially drawn to plants, by any accident of abode or surroundings, no doubt he would have told us of many more. It does not matter. Perhaps we are best off as we are. An excess of botany would have done nothing more for his reputation than the agreeable and temperate sprinkling he has given us, and which is still so grand an illustration of his independence and originality. The way in which the botany comes in always seems to me like his allusions to the tales and impersonations of the Greek mythology; we have plenty, without plethora, enough to show the vast compass of his

acquirements; yet nothing is ever intruded or present without a good reason, and whatever does come, comes gracefully. It is in these latter qualities that we find so much of the secret of his wonderful harpooning power. We feel that in his allusions to trees and plants there is scarcely ever anything but what he got out of Nature as a *bonâ fide* disciple. Instead of glittering crystals, hard and mathematical, dug from the mines of ancient Greece and Rome, such as cover the pages of most of his cotemporaries, and such as are constantly being employed even in our own day, we have the warm sweet fluent reality that pertains to life. In some few cases, without question, his allusions are of the crystalline class. That he got his idea of the Cedar, for instance, from earlier writers, possibly from scripture, and mentioned it because they had done so, must be conceded on the instant, since this tree was not brought to England till many years after his death, or in 1683. The Cypress he may possibly have seen, the introduction of the latter having taken place in 1548, and possibly he may have seen the Myrtle, which shrub was brought from Spain during his lifetime, at the same period as the Orange tree, by Sir Walter Raleigh and Sir Francis Carew. I am inclined to think, however, that his allusions to both plants were founded on hearsay, or, like those which he makes to the Cedar of Lebanon, adaptations of what he had learned from the literature of a remote age.

Another very important matter in regard to the botanical images and comparisons employed by the poets, and which it may be well here to point out, is that in ancient times names held a breadth of significance very different from the precise meaning which to-day is very properly confined to them. That collectiveness should have characterised the ancient nomenclature of plants and trees, is in no degree surprising. Exact ideas as to botanical affinity the ancients were quite devoid of. They grouped things on the most feeble points of resemblance. Because the Acanthus was a thorny plant, the name was extended to the Acacia, and to the Whin; while Robur, which was emphatically the Oak, applied to any of the Cupulifera that were of immense bulk and stupendous age. Relics of this ancient practice survive to our own day, as will be illustrated by-and-by, under particular heads. Here it is needful only to say that Shakespeare is absolutely free from the errors which arose on the supposition that Lily always meant the Lily, *pur et simple*, and that by Acanthus was always intended the leaf which gave to Callimachus the first hint of the Corinthian capital.

The Rose.

"Rose," in its primitive form, is a name of unfathomable antiquity. It belongs to the wide-spread Indo-European family of words which includes our own "red" and "ruddy"—the Latin *rubilis*, and the Greek *rhodon*, all of which various terms are probably referable to some venerable root-word, born thousands of years ago in fertile and patriarchal Asia, and from which, by slow degrees, they have been derived. The etymological meaning appears to be just that which is expressed in our old-fashioned English "red." Strictly, therefore, to speak of a white Rose is an inconsistency. Rhodon, the earliest form preserved in literature, and the first occurrence of which is in Homer's Hymn to Ceres, whatever it may have designated in the beginning, in course of time became the appellation of red-hued flowers in general, and as red flowers are the most showy and conspicuous of any, it very naturally became extended therefrom to flowers of all descriptions, whether red, blue, white, or yellow. This is illustrated in that charming passage in Pindar, when, after comparing domestic trouble and adversity to a wintry snow-storm, he exclaims, "But now this happy household, like the earth, has blossomed with purple Roses."* The epithet "purple," it will be remembered, was, with the ancients, the designation not only of a particular colour; it also denoted bright, luminous, or effulgent, and in the latter sense it is that Pindar, so renowned for his picturesque figures, employs it in the verses quoted. Virgil uses it in precisely the same sense, *ver purpureum*, "shining spring,"† and elsewhere applies it to the white Nereissus, one of the most lucid of white flowers.‡ Horace gives it in the same fashion, to the swan.§ Many passages

* Isth. iii. 39. † Ecl. ix. 19. ‡ Ecl. v. 38. § Odes 1 l. 19.

might be quoted to show that with the ancients Roses often signified flowers in general. One of the prettiest occurs in the episode where we have the bevy of little maids at play upon the shore, delighting in the sound of the dimpling sea, their companion, the daughter of Telephassa, who presently is borne away by the snow-white bull, meantime "culling Roses."* The Egyptian Water Lily, the superb Nelumbium of modern botany, bore, for one of its names, the "Rose of the Nile," and it scarcely needs to be remarked that to this day we speak of the crimson Poppy among the cereals as the Corn Rose, of the lilac field Scabious as the Gipsy Rose, and of the white Hellebore of mid-winter as the Christmas Rose. A beautiful Mallow is called *Hibiscus rosa-sinensis*; the Camellia is with many the Japan Rose. We have also the Rock Rose, the Guelder Rose, and the Rose of Barbadoes. It certainly is very interesting to note, as an illustration of how the ideas of redness and of flowers go hand-in-hand, that the epithet applied to a deep-coloured or rosy human countenance is "florid" or "flower-like." It may be interesting, also, to point out that what is true of the Greek *rhodon* is true in other and very different languages. Metaphor, in its principles, is everywhere alike, because founded upon the natural harmonies of things, and whatever "rose" may denote figuratively in one language, its equivalents will denote the same elsewhere. In the Persian language the word for red is *gul* or *ghul*. Thence, on the repulsive side, comes ghoul, the eater of blood, as in the "Arabian Nights;" while, on the pleasing one, it signifies both a Rose and flowers in general. Gulnare, that beautiful feminine name, so common with the Arabs, is their word for the Pomegranate blossom, and the oriental equivalent of our loveable English "rosy-checked." Gules, the term for red in the heraldry of the Crusaders, is the same original word over again.

At what period the precise word *Rosa* was contrived, or when it first came to denote the Rose specially so called, is not known. The earlier Romans seem to have used *Rubus*, a name subsequently transferred to the Bramble. The species which, in the times of their pride and luxury, they so highly valued, and respecting which so many incidents are mentioned in history, to say nothing of the allusions made by the poets, would seem to have been the incomparable Centifolia, commonly called by the ugly name of the Cabbage Rose; the Damask or Damascus Rose, and, probably, also the African Musk Rose, and the Gallica. Descriptions more or less accurate are given by the naturalists, but which of them filled the famous gardens of Pæstum, remains a pure matter of conjecture. Pæstum, the Poseidonia of its Greek founders, was a delightful locality to the south of Naples, on the gulf of the same name, and was celebrated, not only for the abundance of its Roses, but for their blooming twice a-year. There is no evidence either as to the date of their first appearance in England, though, unquestionably, it was very early. Some of the varieties have probably been in British gardens ever since the occupation by the Romans. When they took their departure the plants would be cherished where so many other things found a refuge during the dark ages, within the precincts of the monasteries, and there the modern pedigree may be said to begin. All four of the species that have been named were known, in all likelihood, to Shakespeare. If there be a doubt as to either it will attach to the Gallica.

The Centifolia, the first and most renowned of the four, is well distinguished by its large and cornuous flowers; the large, unequal, and curving prickles, the clamminess of the calyx, and the concavity of the petals, which remind one of some of those lovely shells we see strewn upon the "yellow sands." The fruit, also, is characteristic, being oblong or rounded, but never elongated; the leaves, again, are large, compared with those of other common species of Rose, and the height, in full-grown plants, is 5 or 6 feet. The name is apparently an adaptation of the ancient one bestowed by Theophrastus, whose hecatophyllon or Hundred-leaved Rose grew abundantly in the neighbourhood of Philippi. This plant is probably intended also by Herodotus, in his reference to a *Rosa* indigenous to Macedonia, which had sixty petals, and was remarkable for its fragrance. Whether indigenous or not to south-eastern Europe, there seems to be no doubt that

this lovely plant occurs truly wild in certain parts of the Caucasus, where it was noticed by Bieberstein, sometimes with double flowers, and whither it was not likely to have travelled from a garden. This was the Rose, *par excellence*, in ancient times; the Rose which the Greeks dedicated to Aurora, as an emblem of youth, because of its freshness and reviving fragrance; to Aphrodite, as an emblem of love and beauty; and to Eros, as a symbol of fugacity and peril; the charms of love, though so full of allurements, being transitory, and thorns being inevitable. The restless little deity, says the legend, gave one to Harpocrates, the god of Silence, to imply that love is not for disclosure, wherefore the gift of a Rose to this very day, when we wish to impose secrecy, and the celebrated phrase "under the Rose." This is the beautiful flower which, according to the author of the "Episodes," is unvisited by any insect, except that large, handsome, shining, green and golden beetle, the *Cetonia aurata*, in the south of England called the goldsmith. This, too, is the flower which in respect of its equal charms, whether in bud, or fully open, is unique. With the ancients, Roses, while unexpanded, were so much admired, that it was sufficient to speak of them as "buds." Theocritus calls them simply calyces, or flower-cups.* In Shakespeare we have that beautiful passage, where the unhappy Constance says to her boy, the pride and joy of her heart, ill-fated little Arthur:—

But thou art fair, and at thy birth, dear boy,
Nature and fortune joined to make thee great.
Of Nature's gifts thou may'st with Lilies boast,
And with the half-blown Rose.†

This one again, the Centifolia, is assuredly the flower intended in that most lovely picture of premature winter, when

Hoary-headed frosts
Fall in the fresh lap of the crimson Rose;‡

and which, in another place is intended to suggest the idea of a smiling female countenance, when, at all events to the lover, it

Looks as clear
As morning Roses newly washed with dew.§

In regard to the same, come the immortal lines spoken by Juliet:—

What's in a name? That which we call a Rose
By any other name would smell as sweet.
So Romeo would, were he not Romeo called,
Retain that dear perfection which he owns
Without that title.¶

And, by and bye, in the same tragedy, when the operation of the sleeping-draught is described to her by Friar Laurence, comes in all its warmth the sweet old metaphor, as old, at least, as the time of Theocritus, in whose twenty-third Idyll we have "rosy-checked":—

The Roses in thy lips and cheeks shall fade
To pearly ashes.¶¶

I cannot but think that it was the Centifolia which Shakespeare had in his mind also when Laertes addresses Ophelia as "O Rose of May!"*** The association was not with the May of the calendar, but with the early summer of woman's life, when her cheeks as well as her hopes are clad in roseate. Would that all our young ladies would receive the truth that rose colour is only oxygen in another shape, and that cheeks get it best where the flowers do—out of doors. The Centifolia was at one time called the Provins Rose, whence Miller's name of *Rosa provincialis*. It is under this name that Shakespeare alludes to the ribbon rosettes worn by players as ornaments to the shoes.†† The same species has furnished the beautiful variety so much valued as the Moss Rose.

The Damask Rose is distinguished by its pale green, far-apart, pubescent leaves; the greenness of the bark upon the shoots, the long, reflexed sepals, and the elongated fruit. In colour it is exceedingly brilliant; wherefore in Pliny, who calls it *Rosa Milesia*, it bears the happy epithet of *ardentissima*, "very burning."‡‡ As implied in the name, it is a native of Syria, where it attains the height of 8 feet. Shakespeare

* Moschus, Idyll, ii. 35-36.

* Idyll, iii. 23. † King John, iii. 1. ‡ Midsummer Night's Dream, ii. 2.

§ Taming of the Shrew, ii. 1. ¶ Romeo and Juliet, ii. 2. ¶¶ Ibid. iv. 1.

** Hamlet, iv. 5. †† Ibid. iii. 2. ‡‡ Lib. xxi., cap. 10.

evidently knew it well, delighting especially in the deep rich colour of the petals.

She never told her love,
But let concealment, like a worm in the bud,
Pine on her damask cheek.*

So again in Phebe's description of the Shepherd:—

There was a pretty redness in his lip;
A little riper and more lustrous red
Than that mixed in his cheek.
'Twas just the difference
Betwixt the constant red and mingled damask.†

"Mingled damask" seems to refer to the admixture in the cheeks of different shades of their natural hue, such as never occur in the lips, the colour of which is uniform.

The Musk Rose is told quite as easily as the preceding, being a plant of very rambling habit of growth. The branches, which are often 10 or 12 feet long, are too weak, as a rule, to rise or stand without assistance from kindly neighbours. The flowers are produced in large umbellate clusters, which arise from the extremities of the branches; the petals are pure white, but there is a variety in which they are delicately tinged with blush. The musk-like perfume is very perceptible, particularly in the evening, and coming chiefly at this hour, in connection with the purity of the white, we need not wonder that the flower recommended itself to poetry and to Shakespeare. Mark the taste with which he connects it exclusively with Titania and the fairies, the only play in which it is mentioned being the *Midsummer Night's Dream*, where we find it, on three separate occasions. Musk Roses lay upon her couch; they are the same with which she proposes to adorn the head of Bottom; and a part of the duty of the attendants is to "kill cankers in Musk Rose buds."‡ This exquisite species, which in the wild state extends all across the African continent from Egypt to Mogador, occurring also in the island of Madeira, assuredly deserves to reckon with the most delightful of the old English Roses. Quite uncared for by modern connoisseurs, it is prized in many a cottage and farmhouse garden, and ought to be found in many another, if only because it was one of Shakespeare's flowers. I take it to be the Rose which Virgil intends in his description of Venus, when "turning about, she gave a bright display of her rosy neck."§ Shining whiteness of the neck being appropriate to a goddess, and the idea of redness absurd.

The Gallica approaches the Centifolia, but has coriaceous leaves and nearly globular fruit; the flowers, also, are borne differently, being nearly or quite erect. No specific mention of this one appears to occur in Shakespeare; the plant is interesting, however, as being the parent of that curious and interesting form with variegated petals, called the "York and Lancaster." The variety in question appears to be comparatively modern, not being mentioned by Gerard; nor even, at a later date, by Parkinson. The assumption of the red and white Rose respectively, as badges of the houses of Lancaster and York, took place in the Inner Temple Gardens; so, at least, it would appear from the scene in *Henry VI.*, which depicts the quarrel between the famous rivals:—

This brawl to-day,
Grown to this faction, in the Temple Garden,
Shall send, between the red rose and the white,
A thousand souls to death and deadly night.

The above are by no means the whole of the Shakespearean allusions to Roses, but they suffice to illustrate their temper.

G.

The Common Puff-ball in its Mature State.—I send you a morsel of Fungi, taken from a huge specimen found at Innerleithen, filling a vacuum amongst large stones, and entirely covered with soil. Had space admitted development, it is impossible to say what size it might have attained.—J. Munk, *Clarendon*. [Reply by Mr. Worthington Smith:—All Puff-balls ultimately dry up into a dusty mass of threads and spores; the Fungus referred to in this note is the Giant Puff-ball (*Byssoperdon giganteum*), and the specimen enclosed belongs to that species in its ultimate dusty condition. This stuff used to be employed as tinder by country folks, and is now often used to assuage bleeding.]

* Twelfth Night, ii. 1. † As you like it, iii. 5. ‡ *Midsummer Night's Dream*, ii. 2, iii. 3, iv. 1. § *Æneid*, i. 102. | Act ii. scene 4.

CHINESE GARDENS.

GARDENING has been studied and practised by the Chinese from time immemorial, and many of our most beautiful decorative trees, shrubs, and flowering plants have been derived from China, the gardens there being very rich in variegated plants, and especially in dwarfed and double flowered forms of vegetation. Nearly a hundred years ago the skill and enterprise of Chinese gardeners attracted the attention of Sir William Chambers, one of the most noted landscape architects of the time. Speaking of their gardeners, he says:—"Far from being either ignorant or illiterate, they are men of high abilities, who join to good natural parts most ornaments that study, travelling, and long experience can supply them with. It is in consideration of these accomplishments only that they are permitted to exercise their profession; for, with the Chinese, the taste for ornamental gardening is an object of legislative attention, it being supposed to have an influence upon culture in general, and consequently upon the beauty of the whole country. They observe that mistakes committed in this art are too important to be tolerated, being much exposed to view, and in a great measure irreparable, as it often requires the space of a century to redress the blunders of an hour." We are told that their spring scenes "abound with evergreens, intermixed with Lilacs of all sorts, Laburnums, Limes, Larches, double-blossomed Thorn, Almond and Peach trees, with Sweet Briar, early-flowering Roses, and Honeysuckles. The margins of thickets and shrubberies are adorned with wild Hyacinths, Wallflowers, Daffodils, Violets, Primroses, Polyanthus, Crocuses, Daisies, Snowdrops, and various species of Iris, with such other flowers as appear in the months of March and April." In addition to these glimpses of early beauty, their summer scenes are said to "compose the richest and most studied parts of their gardens, and are formed by grouping nearly every fair deciduous flowering plant and shrub that will grow in the climate, all uniting to form the finest verdure, the most brilliant and harmonious colouring imaginable." Their autumn scenes are said to consist of many sorts of Oaks, Beech, and other noble deciduous trees that are retentive of leaf, and that afford, in their decline, a rich variegated colouring, with which they blend evergreens, fruit trees, shrubs, and flowers that blossom late in the year. Even during the winter months a pleasing effect is obtained by grouping Pines, Firs, Cedars, evergreen Oaks, Phillyreas, Hollies, Yews, Junipers, and many other evergreens, these groups being further enriched by a judicious use of Laurels, Laurustinus, Arbutus, and other plants of distinct habit that will flourish out of doors during the colder part of the year; and, in order to give variety and interest to the winter scenery, we read that they plant many of the rare shrubs, trees, and flowers of the torrid zone, which they cover during winter with glass frames, warmed by subterranean fires or other artificial means—a circumstance which shows that geothermal culture was not unknown in China a century ago. Our illustration owes its attractiveness mainly to the artistic disposition of the rock-work and water—garden embellishments well understood by the Chinese. On the rocks are planted many "kinds of Grass and creepers, and shrubs which thrive in such situations, together with Mosses, ground Ivy, Ferns, Stonecrop, and various other sorts of Sedum, Houseleek, Cranesbill, rock Roses, and Broom, with Birch and other elegant trees that root into the crevices and assist in draping bare surfaces in an effective manner; while, on the summits, are placed hermitages and temples, to which one ascends by means of rugged winding steps cut in the face of the rock." These hermitages are not always useless accessories; on the contrary, they frequently afford shelter to aged and infirm gardeners and other dependants of rich mandarins; who, instead of being turned adrift when unable to work, are here allowed to end their days in peace and comfort, surrounded by scenes with which they have, in most cases, been associated from childhood. Water forms a prominent feature in nearly all the best Chinese gardens; indeed, Chinese artists assert that no garden, particularly if it be extensive, can be perfect without it. Its extent is generally cleverly concealed by means of various devices, such as the introduction of islands and groups of trees. The trees used for such purposes are the slender silvery-barked Birch, columnar Poplars and Cypress, Laburnums, Larch, or Weeping Willows, the pendent

A MODERN CHINESE GARDEN.

branches of which frequently dip down gracefully to the very water's edge. There are few countries in which greater diversity of trees, shrubs, and smaller decorative plants are cultivated in the open air than in China, a circumstance partly due to the fine inter-tropical climate possessed by the southern provinces, and partly to the skill and enterprise of the Chinese gardeners, who employ every distinct and beautiful plant obtainable, in order to form the scenes to which we have just alluded. In the more extensive of these gardens even some of the effects of woodland scenery are obtained by massing Oaks, Elms, Beech, Tulip trees, Planes, Maples, and Sycamores, Walnuts, and Limes, which form bold rounded masses of varied tints; and with these are judiciously contrasted striking columnar Poplars, Conifers, and other trees of a spiral kind, so as to vary the outlines and add variety. Even herbaceous plants are arranged so as to form a series of little scenes or pictures on the outskirts of borders or plantations of hardy shrubs, instead of being indiscriminately planted in strips without any special object in view. It is stated, indeed, that the best Chinese gardeners dispose of them with great circumspection, and "paint their way very artfully" along the borders in which they are planted. They reject all plants of very straggling growth, harsh colours, and poor foliage, choosing only such as are of some duration, either in large or in picturesque masses, or such as are either graceful in form, with fine foliage, or of tints that harmonise with the colours and bright green foliage with which they are associated. In the culture of tender pot-plants for the decoration of temples and apartments, few cultivators excel the Chinese. Decorative plants are largely used in their various temples, especially during the ceremonies which take place at the new year. These include Chrysanthemums, Narcissus Tazetta, Delytras, and scores of other plants. In few other countries of the east is the soil so well cultivated as in China, and wherever the Chinaman emigrates, he is found to turn his cultural proclivities to good account; nowhere is this seen to better advantage than in San Francisco, Chicago, and other cities of the United States, to which, of late years, Chinamen have flocked in large numbers.

F. W. BURBIDGE.

Dangstein.—The best private collection of rare plants I have ever seen is at Lady Dorothy Neville's, at Dangstein. I went there with a party of friends a few days ago, and was perfectly charmed with the beauty of the place and the numerous curious specimens to be found there. Wonderful Ferns from all quarters of the globe, exquisite Pitcher Plants, singular Orchids of great value, Tea, Coffee, and Croton-oil plants, the Lattice Leaf plant (*Ouvirandra fenestralis*), and a marvel of a terrestrial Orchid belonging to the *Amnctochilus* family, all attracted my attention so much that I could scarcely be constrained to take a peep at her ladyship's famed silk-worms, feeding on their favourite food, the leaves of the *Ailantus* tree. Of one thing I feel certain, that the Silkworm cannot, at least in the caterpillar state, have a keen sense of smell, otherwise, the odour of these leaves would dismay it. Truly, the grounds, gardens, and various houses at Dangstein are well worth a visit.—HELEN E. WATNEY, *Berry Grove, Liss.*

Death from the Sting of a Hornet.—The deputy coroner for the Reading Division of Berkshire has held an inquest at Mortimer, a village near Reading, touching the death, under extraordinary circumstances, of Mrs. Sarah Merrett, a labourer's wife. Deceased was standing in the road near her house when a hornet flew out from a nest in the bank and stung her on the right side of her neck. She went indoors, and a neighbour bathed her neck with water and vinegar. However, she fainted almost immediately and expired in a few minutes, before a medical man could reach the house. Mr. G. H. Davis, surgeon, stated at the inquest that he knew Mrs. Merrett as a nervous, excitable woman, and he believed the immediate cause of her death was syncope, the result of a nervous shock caused by the sting of the hornet. The jury returned a verdict in accordance with that opinion. Deceased was fifty years of age.

Guarana as a Remedy in Cases of Nervous Headache.—Guarana, made from the bruised and roasted seed of the *Paullinia sorbilis*, growing in Brazil, contains an alkaloid allied in character to that found in tea and coffee, and which comes nearer to a specific for sick headache, and any other ill-effects from over exertion, than any remedy I have ever found for any disease, in a practice of over forty years. Taken at the first warning of an attack, it will ward it off entirely in nine cases out of ten, and do more than any medicine I have ever found to prevent its return.—*Cultivator.*

THE FRUIT GARDEN.

FRUIT-GROWING FOR THE LONDON MARKETS.

OF orchards there are but few properly so called in the neighbourhood of London; the large area devoted to fruit tree growing being also used for the production of vegetables. There are, however, a few "Grass" orchards, but these are the exception rather than the rule. The trees, for the most part, are of the old-fashioned large standard kind—in short, regular orchard trees—but as these die out or are removed, they are replaced by young ones, which are, as a rule, more carefully trained. The tall large-headed trees of olden times are giving place to dwarf ones, which not only produce good crops of large fruits, but afford special facilities for gathering the produce, and also permit the ground underneath them to be cropped with better results than in the case of large, widely-spreading trees. Thus, when a failure of the fruit crop takes place, its effects are only partially felt, as there is the vegetable crop to fall back upon. Low-worked, bush-shaped trees are preferable to pyramidal ones, as they are more prolific, and not so subject to the influence of high winds. The last fortnight in July and throughout the month of August (the Apples then usually bending the branches into the form of arches, Pears being found in loads ripe and ripening, and Plum-tree boughs supported with props, in consequence of the heavy crops which they are producing) is perhaps the best time to see fruit trees in market gardens in perfection. Orchards were at one time planted in rows at various distances, varying from 9 to 15 or even 20 feet apart; but in many cases these lines have been much thinned by natural causes as well as by the saw; the blanks thus created having been for the most part planted with young trees that become so choked as to be as short-lived as their ancient neighbours. On the contrary, where entire clearances have been made, and a whole field is planted afresh, no matter whether the distance be 6 or 18 feet from row to row, the trees look thriving and fruitful, and, in excellence, promise to surpass their predecessors. Market gardeners make it a point not to plant the rows of a new plantation exactly in the place which the old ones occupied, but rather between where the old ones grew. Fruit trees are also sometimes planted in lines, so as to form boundaries to quarters or large squares of ground, thus affording shelter to the vegetable crops. A 50-acre piece of excellent ground, quite level, I observed treated as follows:—It was divided crosswise by means of five rows of Pear and Apple trees; between these rows were open fertile spaces for vegetables, the ground thus being cropped up to the base of the trees, which annually bore good crops. Where trees of these kinds are closely planted the vegetables are good. As soon as the leaves have fallen the surface of the ground is cleared of all remains of previous crops, prunings, and similar litter. It is then manured and dug over for Radishes. This crop is partially sheltered in winter by the naked branches, and is removed before the leaves again unfold. Parsley from July sowing, transplanted in autumn under fruit trees, does well, and Mushroom beds bear abundantly in similar positions. Under fruit trees is almost the only place assigned to Wall-flowers and bulbous plants, and there, too, Leeks and early Potatoes are often grown. Sprouting Broccoli, Brussels Sprouts, Spinach, and Kale are the recognised crops for such shady places during the summer and autumn months; and, although it must be admitted that these do not thrive so well as they would do in the open field, yet they succeed moderately well, and amply repay any trouble bestowed on them. Such herbs as Thyme, Mint, and Sage are also often grown under fruit trees. Perhaps the best of all crops for such situations is Rhubarb; plants of it thus placed are usually the first to start into growth; and, under the overhanging boughs, the stalks come up more tenderly than they do in open quarters, but their inferiority in point of colour lowers their market value. Moss Roses, Gooseberry and Currant bushes, are likewise extensively grown between the rows of fruit trees, where, considering their position, they usually yield fair crops; but a great drawback to such intercropping, where the trees are closely planted, is that the drip from them causes a deal of grit to lodge on the berries. Except in the case of young trees, little is done in the way of pruning or training. All the pruning old trees get

merely consists in cutting away annually with the saw all dead or dying limbs, or thinning out some of the worst placed branches, in the event of the tops being too much crowded. Market gardeners dislike hard pruning; still, many of them, although adhering in the main to the old system, use the knife a little, and branch thin the big standards to a greater extent than was wont to be done, and they admit that by this practice better fruit is produced. Although considerable knife pruning is necessary for very young trees, yet, as soon as fruit-spurs are induced and gross growth subdued, hard pruning is gradually discontinued. It is very desirable to have the trees somewhat open in the heart, and the branches well exposed to the sun. In market gardens fruit-tree ground is manured just as heavily as open quarters, if vegetables are to be grown on it, and in winter it is trenched and ridged, or deeply dug up to within a very short distance of the trunks of the trees. This may seem bad practice, and in ordinary cases, doubtless, it would be; but in market gardens deep soil and heavy manuring help to repair the evil. The suckers that spring from the trees are lifted with the roots attached to them at digging time, and are either kept for stocks, or are disposed of to nurserymen or others for a similar purpose. When lifted, they are usually "heeled" in in bundles in a piece of out-of-the-way ground until a convenient time arrives for planting them in rows, when they are trimmed root and stem, and planted in rows 2 feet apart in well-trenched and manured ground; afterwards they are treated as is done in nurseries. During the first, and in many cases the second summers, Spinach, French Beans, Turnips, Cabbages Asparagus, or Beet are sown between the lines, or Seakale is planted there. Here they may remain until fit for grafting, when they are worked some 6 inches from the ground, using grafting clay over the incision, and earthing up sufficiently high to cover the union, so as to keep the clay moist. Sometimes, however, these stocks are grafted some 3 or 4 feet high, and clayed as in the other case; the stocks are then bent on one side, so as to lie near enough to the ground to permit the grafts to be buried in the soil. When the union is considered complete, the soil is taken away, and, after a lapse of some days, the clay is likewise removed. Market gardeners do not, however, raise all their own fruit trees; on the contrary, they obtain their chief supply from nurserymen. Where it is desirable to graft another kind on an old tree, in order to replace a lost limb, or for any other purpose, the part to be grafted is cut back some weeks before "working." During the summer time fruit trees in market gardens get but little attention until the fruits ripen, when harvesting them, either for storing or for immediate marketing, requires much time and care. In gathering, large baskets are usually set here and there in the orchards, and the pickers collect the fruits into smaller ones, and empty them into the large ones, according to the kind. The fruits are then either sorted on the spot, or are conveyed to the packing shed. The largest, medium-sized, and smallest fruits are all picked out and kept separately, as they sell better when thus sorted than when all are mixed. Lime is often dusted over fruit trees to keep down caterpillars, and other leaf-eating insects. Limewash, too, is frequently painted on the main stems after they have been scraped clean in winter. This is to prevent the ascent of insects from the ground, and to prevent the growth of Lichen; but some consider it of little use. F.

Queries Respecting Vines.—The following replies furnished by Mr. Thomson, of Clovenfords, may be taken as trustworthy answers to the questions to which they respectively refer. When is the best time to plant Vines? [From the end of February to the beginning of April.] What are the best Grapes for two houses, each 14 feet long—one with stove and the other with greenhouse temperature—both well furnished with heating power? [The space (14 feet) will admit of five Vines being planted in each house; the varieties best suited for the stove are, two Muscats of Alexandria, one Tynningham Muscat, one Mrs. Pince, and one Gros Guillaume; for a greenhouse, with or without fire heat, select three Black Hamburgs, one Duke of Buccleuch, and one Royal Muscadine.] What is the right age and condition of the Vines for planting? [Twelve months is the time a Vine requires to get into a proper condition for planting. Struck from eyes this spring, grown on throughout the summer, and well ripened in autumn, they are in fine order for planting the following

spring. Vines struck in spring and planted in May in a growing state are, however, in every way best.]

A Novel Cure for Diseased Vines.—The Abbe Rolland has communicated to the *Cultivateur de la Région Lyonnaise* an "infallible remedy" against the Phylloxera, which, after two years' trial, he recommends "with confidence" to Vine growers. It consists in inoculating the Vine with the pure essence of Eucalyptus globulus, which has lately attracted so much attention in medical circles. A broad incision is made through the bark at the neck of the Vine, in which a few drops of the essence are deposited by means of a small camel-hair brush. The result is, that in about three days the Phylloxera entirely disappears, while the Vine is not in the least injured by the operation. The incision may be made through any other part of the bark with equal success; but the result is more speedily attained the nearer it is made to the roots.

Another Early Peach.—We received on the 15th of July a few specimens of Amsden's June Peach, a very early kind, from our old correspondent Mr. Teas of Carthage, Mo. They were in good order after so long a journey. The specimens received measured a little over an inch and a half in diameter for the smallest, and the largest nearly two inches. They were forwarded from Carthage on the 10th. Mr. Teas, whose statements can be fully relied on for accuracy, informs us that the original tree has been allowed to over-bear, and he was not able to procure good specimens. On trees two years from the bud many of the Peaches, when cut in two, have measured 2½ inches wide and 2 inches high. Illness prevented his sending these, and also compelled him to defer for two days forwarding those that were gathered. Consequently these last specimens were ripe on the 8th of July. This Peach was raised by Mr. Amsden of Carthage, Mo., and is a chance seedling from an unknown sort, the collection of seeds from which it originated having been gathered from different sources. It fruited for the first time in 1872, and the earliest specimens were ripe the last of June—the latest on the 7th of July. Last year the frost destroyed the crop. This year, although a late season, the first specimens were ripe July 3, and those sent us, on the date already mentioned. With the specimens forwarded was also one of Hale's Early, less than half the size of Amsden's, and perfectly green. Mr. Teas informs us that this was taken from a tree growing alongside, and as good as could be found, with precisely the same soil, situation, and treatment throughout. He further adds:—"Early Beatrice we have bearing a very few. While it is far ahead of Hale's in ripening, it is as much behind Amsden's in earliness and colour, and, as far as we can judge from our samples, not half its size. Amsden's far surpasses Hale's in quality, and is thought to resemble Large Early York. Like that variety, the flesh partly adheres to the small stone." There is no question that this is a Peach, as yet, unequalled for earliness. Allowing a difference of a month in the ripening of fruit at Carthage and in Central New York, it would still be at least two weeks earlier than Hale's, and we are assured by our correspondents at Carthage that there is at least this difference between the two. The tree is stated to be a free grower, hardy and productive, the flowers large, and the leaves with globose glands. The specimens sent us were mostly dark red; flesh, greenish-white, juicy, and with a fine flavour. We cannot but regard it as a valuable acquisition, and shall look with interest to its character when fruited in other localities.—*Cultivator*.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Plums for Wall Culture.—I should like a short list of Plums suited for wall culture; the aspect is a sunny one.—W. E. E. [Greengage, Kirke's Admirable, Coe's Golden Drop, Jefferson, Washington, Magnum Bonum, Orleans, and Reine Claude de Bayay.—Ed.]

Pears for a South Wall.—I wish to devote a good south wall to Pear culture, and shall be obliged by your giving me a list of the very best kinds for this purpose.—J. H. [Jargonelle, Beurré d'Amanlis, Gansel's Bergamot, Marie Louise, Vin Mons Léon le Clerc, General Toddleben, Glon Moreau, Josephine de Malines, Winter Nelis, Bergamotte Espéren, Ne plus Meuris, Easter Beurré, Beurré Diel, Beurré Rance, and Duchesse d'Angoulême.—Ed.]

Old Apple Trees.—The Secretary of the Maine (U.S.A.) Board of Agriculture, in his late report, mentions an Apple tree at New York, that was brought from England over 200 years ago in a tub, and was still bearing fruit in 1870; another, near Wiscasset Bay, that was an old tree in 1805, but is still fruitful; another, in the town of Bristol, known to be over 200 years old, still bearing fruit, and other trees that yield occasionally from 25 to 65 bushels of fruit each.

French Ringing-tongs.—These, though useful, are not so generally used as they deserve to be. As is well known, ringing is generally practised on Vines in order to induce them to produce larger and better Grapes than they otherwise would do. By means of the French ringing-tongs, ringing is made easy, as the operator has only to apply the top of the instrument underneath a bunch of Grapes, and, by turning it round, a small piece of bark is removed by the knives, which are opened and then firmly pressed together by the spring. The same instrument may also be used in the case of Apple and Pear trees.—A. M. C. JOCKINGH CONNICK, *Tottenham Nurseries, Deddington, near Zuelde, Netherlands*.

THE TRAVELLERS' TREE.

(RAVENALA MADAGASCARENENSIS.)

THIS is one of the most striking of all Musads, and one not unfrequently met with in cultivation in this country. A fine specimen of it may be seen in the Palm-house at Kew, and it forms a noble ornament to the conservatory at Chatsworth and other places. The plant has a peculiar appearance, owing to the fan-like arrangement of its great glaucous leaves, which are larger than those of any other ligneous plant having simple foliage. It is nearly related to *Musa* and *Strelitzia*, but differs from both in having six stamens and woody capsular fruit. The seeds of this plant are especially beautiful, being partially surrounded by a clear blue arillas, which shines with metallic lustre when in a fresh state. The plant is a native of Madagascar; but it is also found in the Straits Settlements, especially in Singapore, where it is known as the "Travellers' Fountain," a popular name derived from the fact that the great sheathing

LEAF MUSIC.

THE music of the leaves, always beautiful in its infinite variety, is perhaps, fuller in tone and at its very best just at this particular period. In a fortnight's time its melody will have a harsher sound; it will have a slight discord; it will have a sad undercurrent of melody in a minor key, suggestive of decay and death, a forerunner of the melancholy of autumn, and the gloom and desolation of winter. So charming is this music, so suggestive is this melody, so teeming with fantastic ideas, so replete with poetry and beauty, that it is a matter of great wonder that it has not been long ago utilised by musicians. Why have we not a "Foliage Fantasia," and why has not some one composed a "Leaf Sonata?" What a number of "songs without words" do we hear sung in the upper branches of trees at this period of the year! Is it possible to put down upon paper, is any one equal to the task of producing in type, the myriad of fancies that occur to one, the thousand of sweet songs that are sung for your especial delectation as you fling yourself down on the green-sward and gaze upwards, and start on a dreamy excursion amid the rustling leaves of some superb old Elm? Experts in leaf music,

The Travellers' Fountain Tree of Madagascar.

stalks or petioles are capable of holding a considerable quantity of rain-water or condensed moisture, which trickles down from the flat leaves above, and is readily obtained by piercing the lower part of the sheath and catching it in a vessel beneath. In this way the tree is said to be a great boon to thirsty travellers in the islands in which it luxuriates. As an ornamental or decorative plant it ranks with the Musas, properly so called, and grows well under the same treatment. Fine effects may be obtained by planting out a specimen of it in the richly-manured bed of a warm conservatory, where, under liberal treatment, it soon develops itself. It is sufficiently hardy to withstand our summer climate as a sub-tropical plant, but, when so used, a warm sheltered nook should be selected for it, as its foliage, like that of *Musa* and *Strelitzia*, is extremely liable to be slit or torn by rough winds. Our illustration, from an interesting book of travel entitled "The Land of the White Elephant," represents a specimen met with on a roadside in Singapore, where the plant is said to grow luxuriantly, and Ellis found it growing plentifully in the thickets in Madagascar.

enthusiastic arboriculturists, people who have devoted their lives to the study of this matter, are able to draw fine distinctions between the Elm, the Oak, the Ash, the Larch, the Birch, the Poplar, the Willow, the Plane, the Lime, the Beech, and the Fir. They aver they could tell with their eyes shut any tree by the flutter of its leaves. Though undoubtedly the ear would require education and constant practice to arrive at such accurate discrimination, there is no reason whatever that it should not be achieved in time. One man hears only the singing of birds, but another can tell you exactly what particular kind of bird is singing; there is no reason whatever that the same rule should not be applied to the rustle of leaves. The skeleton of each variety of tree is differently constructed, the foliage of each is of a totally distinct nature, so there is but little doubt that every species of tree rustles in a different key and a different measure. With the finer theories of leaf-music and the more profound depths of the study of foliage-melody it is scarcely necessary to treat in this present paper. It is rather proposed to speak of the subject from a popular point of view, and to show the universality of its influence. Undoubtedly its influence has become greater during the last few years; people will have leaf music if they can have nothing else. You may see in the poorest room in some

close over populated court in the lowest part of the town, a creeper growing outside the window, which by the flutter of its leaves brings back a world of pleasant fancies to its proprietor; you may note that trees are being planted wherever it is possible for them to grow, and you will find even among the ruffians who haunt the Thames Embankment that trees are infinitely more respected than are the ornamental iron railings; and there is but little doubt that if the proposal to plant trees more generally in our streets were carried out, not only would they grow, but they would be rigorously respected and protected by even the roughest portion of the population. Nothing is more unpopular in the present day than cutting down trees. It may be remembered what severe lectures the daily press read the Benchers of the Middle Temple for treating in summary fashion one or two old Elms in Garden Court, and desecrating the quaint, picturesque little enclosure hallowed by the memories of Ruth Pinch and John Westlock. We can call to mind the vigour and enthusiasm displayed by those who are resisting all attempts to convert Epping Forest—with its vast orchestra of tree-musicians—into desolate “desirable building sites,” and it is pretty certain that if Mr. Albert Grant, in the place of erecting a statue of Shakespeare in Leicester Square, had transported thither and planted a few large trees, he would have added to his popularity four-fold. If the Draper’s Company, which by the way is quite rich enough to be able to withstand the temptations of speculative builders, were to decide to preserve their quaint garden with its Mulberry trees, its Poplars, and its Maples, with its pond and its bright green turf, in all its integrity, what an incalculable blessing they would confer on weary mankind! To think there would be a pleasant haven, within the roar of Capel Court, the hum of high ‘Change, and the auriferous babble of Lombard Street, where one could retreat and enjoy a little rest and a thousand exquisite fancies as one listened to the music of the leaves, would be joy indeed. Leaf music is especially valuable in crowded cities, it is rarer, and therefore the more prized. . . . Possibly leaf music is more poetical than the music of the sea, because it has more variety. It is a fascinating study, and the more you pursue it the more enchanting does it become. How often when you have taken your favourite author to read beneath some old tree, do you find that you remain for hours without turning a page! You are listening to the music of the foliage, and the untold fancies and reminiscences that are whispered through it. Come back sweet voices long since hushed; come back the vision of bright eyes; come back the dreams of long ago; come back days that you have forgotten; come back a thousand fleeting fancies and a thousand poems and pictures that you fain would fix on your brain, but which vanish like Thistle-down in a summer breeze when you cease to listen to the music of the leaves.—*Graphic*.

THE ARBORETUM.

PRESERVATION OF TIMBER.

OVER two hundred years have elapsed since a patent was taken out to preserve wood from decay; but the means employed by the inventor of that period were cumbersome as well as costly and inapplicable, except on dry land. The idea was to plaster constructions of timber with a coating of clay. To speak modestly of the progress which has been made in the same direction in the interval, it has not been great. Successive inventors have struck out plans for arresting rot by permeating the wood with creosote or chemical solutions of different kinds; but none of the methods adopted answered either the need or the expectation. The process of creosoting timber is decidedly antiseptic; the vegetable germs are destroyed, but then the moisture is driven into the centre, and the material rendered more inflammable. Then we have had Burntising (so called after the name of the inventor), and kyanising; but though both have good qualities they are open to objections, which are claimed not to be against a system just introduced by the Rev. Dr. Jones, and which was experimented with in presence of several gentlemen on the afternoon of the 8th inst., at the residence of Mr. W. C. Jarvis, the Priory, Tandridge, near Godstone, Surrey. Dr. Jones is confident that his patent will not only avert dry-rot, but absolutely cure it, and render timber considerably less liable to the action of fire. The first experiment was tried on two pyramids, constructed by placing a large number of pieces of wood together, one being “pickled” with the preparation and the other unprepared. A pint of petroleum was placed on each, and whilst all that remained of the unprepared timber was the usual residuum of ashes, that which was soaked with the preparation remained almost intact. The next experiment was that tried on a barrel of the usual Government size, under the head of which was placed a quantity of gunpowder, wrapped in a piece of tissue paper, and then enveloped in brown paper prepared with Dr. Jones’s solution. Though subjected

to the heat caused by petroleum being poured over unprepared shavings, the gunpowder did not explode even when the flames were directed to the interior of the barrel. When taken out the gunpowder was found in precisely the same condition as it was prior to being subjected to fire. The third experiment was that of setting fire to two wooden houses, one being prepared by the process and the other not so treated. In the instance of the former, though subjected to the heat caused by a large fire being placed in the centre of the basement, the floor was but slightly charred; in the other, as might have been anticipated, the flooring was completely burnt, and had time been allowed the whole structure would have been destroyed. A fourth experiment was that of subjecting a wooden box, of several inches thickness, to the flames of a fierce fire for some fifteen minutes. When taken out the exterior of the box was but little charred, and on it being opened a parchment deed, to which a large seal had been attached, was found unharmed, the sealing wax itself not presenting any appearance of having suffered from melting. After these tests of the efficacy of the treatment had been concluded, these present were shown a piece of timber taken from her Majesty’s ship “Lord Clyde,” which had been restored from a state of almost pulp to its normal condition.

A Murdering Liane.—The Fig springs up close to the tree on which it intends to fix itself, and the wood of its stem grows by spreading itself like a plastic mould over the stem of its supporter. It then puts forth, from each side, an arm-like branch, which grows rapidly, and looks as though a stream of sap were flowing and hardening as it went. This adheres closely to the trunk of its victim, and the two arms meet on the opposite side and blend together. These arms are put forth at somewhat regular intervals in mounting upwards, and the victim, when its stranger is full-grown, becomes tightly clasped by a number of inflexible rings. These rings gradually grow larger as the murderer flourishes, rearing its crown of foliage to the sky, mingling with that of its neighbour, and in course of time they kill it by stopping its flow of sap. The strange spectacle then remains of the selfish parasite clasping in its arms the lifeless and decaying body of its victim, which had been the help of its own growth. Its ends have been served, and it has flowered and fruited, reproduced and decimated its kind.

A Fine and Rare Shrub (Stuartia pentagynia).—We have few ornamental shrubs which show flowers at the end of summer; hence our appreciation of those blooming at that season. The Phloxes, Gladioli, and various summer-blooming herbaceous and bulbous plants, keep the garden gay and relieve the monotony of those “walls of green” formed by dense groups or borders filled with only late or early flowering shrubs. Still, a little variation from general appearances is sometimes quite a relief to the eye. I was reminded of this by noticing the other day that a large plant of this *Stuartia* was in full bloom, its large, pure white, shell-like flowers peeping out from among the deep green leaves of the surrounding plants in a most fascinating manner. This elegant shrub is a native of the mountains of Virginia and still further south; it is far superior in all those qualities which go to make up an elegant ornamental shrub than nine-tenths of the far-fetched and dear-bought varieties imported from China and other distant countries. We have two native species of *Stuartias*, both superb ornamental plants. The *S. virginica* is also a native of the Old Dominion and further south, but is found chiefly in low grounds along the borders of streams, and is not quite as hardy as the *S. pentagynia*, therefore it is likely to be winter-killed when cultivated in the more Northern States. It is a beautiful shrub, growing 8 to 10 feet high, with finely serrated leaves and pure white flowers 2 to 3 inches in diameter. The *Stuartia pentagynia* being a native of more elevated regions is, in consequence, more hardy, never having been injured in my garden during our severest winters. It is a handsome, erect-growing shrub, with ovate-pointed leaves 5 to 6 inches in length; petals, white, with finely fringed or jagged edges.—*Moore’s Rural*.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

A New Andean Cranberry (Vaccinium Mortenianum).—In my paper on the Hardy Ericaceae (see No. 143, page 111), you make me say *Vaccinium Myrtillus* instead of *V. Mortenianum*. The latter is a beautiful new evergreen species introduced by J. Anderson-Henry from the Andes, clothed in spring with pink flowers, and now with numerous purple berries covered with a white powdery bloom.—JAMES McNAB.

Curious Growth of Hawthorn.—A very curious phenomenon was noticed upon a Hawthorn the other day in Cheshire. On a perfectly healthy bush, on which the fruit was ripening, there was one branch apparently withered, not a single leaf upon it, but in the place of the leaf-buds were small close clusters of white flowers, giving the whole branch much the appearance of the Blackthorn. It was as if the flow of sap had met with a sudden check in the spring, and the branch was unable to produce its leaves, but recovering itself in the warmer weather, managed to produce its flowers six or seven weeks behind time.—G.

THE KITCHEN GARDEN.

WHAT TO DO WITH THE POTATO CROP.

THE season being so far advanced with little or no disease of consequence, the Potato crop may be looked upon as safe from the dreaded disease, which, from the first year of its visitation, has never appeared in a virulent form after July. But the crop, except in the best Potato land, or where the soil is of a deep alluvial nature and somewhat damp, will not be heavy, nor particularly good in quality. In many parts of the country, even the second early varieties were severely cut with the late frosts. This always has the effect of reducing the size of the tubers at taking-up time; but the principal cause in affecting both quantity and quality is the continued drought, which in far the greater portion of the country has checked growth to a damaging extent. What remains of the early sorts yet in the ground should at once be taken up; for, in their case, after the tops are dead down, nothing can be gained by allowing them to remain longer. The second earlies and late sorts, since the third week in July, have shown unmistakeably in most places that growth had stopped, the under leaves flagging in the sun, and the tubers, when examined, being found to have the eyes just starting about the size of pin heads. Whilst the soil remains in its present dry state, there will not be much danger of the tubers pushing this second growth to a serious extent; but as soon as rain comes in any quantity, they will at once begin to form the second tubers. Such of the second early sorts as have their skins tolerably firm, and not easily removed with the hand, are better taken up; but the late varieties, the tubers of which are young and the skins tender, are better left in the ground whilst the weather continues as it is. But as soon as enough rain falls to excite them, up they must come without any delay, for the second tubers they push are fit for nothing but pigs. I speak this from actual experience, having tried the effects of taking up at different periods, after the stoppage of their growth through drought in seasons similar to the present. Pitting Potatoes is a barbarous system under any circumstances; on no account should these prematurely-taken up, half-ripened Potatoes be stowed away in pits; they should be laid, not too thickly, in a darkened building, as cool as they can be kept, and turned over two or three times during the next three months, to prevent anything like heating. From lengthened experience in Potato culture, I have long come to the conclusion that the time for taking up the crop is the time to commence preparation of the seed for the succeeding year, in the case of either early or late varieties, by fully exposing them to the open air, so as to allow their becoming thoroughly green. In the case of the limited quantities required for garden culture, they should be kept where they can receive as much light all through the winter until planting time as will prevent the sprouts becoming drawn and weakened. By nothing short of this can the seed be in a state best calculated to have a reasonable chance of producing a crop that will escape the disease. The advantages gained by this continued exposure to the light are two-fold. First, that the sprouts never become lengthened and weakly, so as to cause their being easily broken off in the operation of planting, with the consequent weakening of the tubers produced by the second effort; secondly, by the retention of the first sprouts in a strong vigorous condition, this treatment ensures the crop coming to maturity something like a month earlier than when the seed has been treated in the usual way. As to the exposure of the seed for the purpose of greening, if the disease at all makes its appearance amongst such as are yet in the ground, any that are laid in the open air greening should at once be removed under cover; for, even if there are no other Potatoes within some hundreds of yards, the exposed ones will become affected to even a greater extent than if they had been in the ground, and in a growing state. This I experienced some dozen years ago, to such a degree that not more than one-twentieth of the seed so exposed escaped; a circumstance that was so far conclusive with me, as to warrant the conviction that the spores of the disease are present in the air only requiring such conditions of the atmosphere as are favourable to their development. So far as the influence of greening the seed and keeping it where too early and a weakened condition of the sprouts will not be produced, I may be charged

with repeating advice a hundred times previously given; but where we see, year after year, the seed, in cases innumerable, still treated in the same barbarous manner, with little attempt at a better system, it becomes almost a duty to continually urge the necessity for a more rational treatment for this indispensable vegetable.

T. BAINES.

Keeping Old Potatoes.—Potatoes, to be good, should never be exposed to the light, but be kept in as dark a place as possible. After they begin to sprout in the spring they should be taken up from the bins or heaps, and be kept in boxes or barrels. If you have a few barrels saved out for family use, instead of picking them over and spreading them every few weeks, put them into enough barrels so that you can easily turn them from one to another. Have one extra barrel, and once every week turn them all out from one barrel to another. This keeps them moving so often, that the sprouts cannot grow enough to do much harm. The sprouts which come out from the Potato use up the nourishment it contains, and leave it soft, watery, and insipid. By treating them as proposed above, they may be kept in condition for the table several weeks longer than by sprouting them, and at the same time save a deal of work.

The "New" Asparagus.—As some may be incredulous on the subject of making a new variety out of the old and common sort, and at the same time make the people, or a larger portion of them, believe it, we have only to call to mind the so-called "Conner's Colossal" Asparagus, which was brought out as new, at a big price; and, according to an able correspondent of Moore's *Rural*, no uninterested party has ever been able to discover wherein it differed from the old and common sort. But the parties interested in bringing out this pseudo new variety are deserving of much credit in recommending that the roots be planted at a far greater distance apart than the old sort, for it was said that this giant required room corresponding with its size; and herein lies one of the secrets of its success, as well as many of the endorsements regarding its distinctive and superior merits. This recommendation of allowing more room in which to grow is also the secret of the continued success; and, at the same time, it is a great innovation upon the old-time system of crowding the roots, as recommended in all of our earlier standard works on vegetable gardening.

The Autumn Mousseron (*Agaricus prunulus*).—This is just now putting in an appearance on the grassy borders of woods and in sheltered pastures. Not a vestige of the spring Mousseron is now to be seen. The cap of *A. prunulus* is of snowy whiteness when it first appears; even the gills, in the young stage, are white, though, as the Agaric attains maturity, they change to pale salmon. They are conspicuously decurrent on the stem, which is slightly bent and bulboid, with felt-like down clothing it below. The spores in *prunulus* are rosy-salmon and pip-shaped; those in *gambosus* white and oval. Both Agarics have a strong smell of fresh meal, and both are esculent and savoury, requiring, however, more cooking than the common Mushroom. No difficulty should be found in identifying this species; I will add, however, a further diagnosis: The young snow-white cap is waved and contorted, as in the spring Mousseron, smooth to the touch, like a white kid glove, and revolute at the edge. The gills groove the upper part of the stem; they are white in youth, the white assuming a pale salmon colour with age. The gills are in sets of five varying lengths. The stem is firm, white, bulboid, and clothed with byssus at the tortuous base. These characters should be sufficient to enable an ordinary observer to distinguish it at once. This Agaric is sold, in the markets at Paris, dried, and used as a seasoning to gravies, like the Morel.—PETER INCHBALD, *Hovingham Lodge, York*.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Asparagus Culture in Germany.—It is asserted that near Braunschweig, Germany, 25,000 acres are cultivated in Asparagus, most of which is canned. The variety cultivated is called *Rose Hollande*. We have received and eaten samples of this German canned Asparagus, and it is most excellent.

Culverwell's Prolific Marrow Pea.—We have received a sample of this Pea from Mr. Culverwell, of Thorpe Perrow, who states that it is the result of a cross between Veitch's Perfection and Champion of England. It grows about 18 inches higher than Veitch's Perfection, and is very prolific. The pods set were large and well filled, and the flavour all that could be desired. To tall-growing Peas it is a very remarkable addition.

Planting Asparagus in Summer.—Chief Gardener Strenbel, from Karlowitz, read an essay before the Society for Garden Culture in Breslau, Germany, in which he advocated the planting of Asparagus during the summer, instead of in the spring and fall. He gave as his reasons that, by planting in spring, two different functions were required of the plant, viz., to take root and to continue to grow. By fall planting, the actions of the plant remain dormant until spring, whereas, by summer planting, the plant gains time to attach its roots, and then is ready for a vigorous growth in the spring. No particulars are added as to the condition or age of the plants at planting time.

FERTILISATION OF WILD FLOWERS BY INSECTS.

A LECTURE on common flowers in relation to insects, was delivered to the British Association, at Belfast, the other evening, by Sir J. Lubbock, who, after a short historical introduction, in which full justice was done to the labours of his predecessors, especially of Sprengel, Darwin, and Muller, went on to say:—While every one knows how important flowers are to insects, comparatively few are aware how important, on the other hand, insects are to flowers. Many flowers, indeed, are entirely dependent on insects for the transference of the pollen from the stamen to the pistil, without which no seed could be set; while, in others which can fertilise themselves, it is yet of the greatest importance by avoiding “in and in” breeding. Every breeder of cattle or sheep will appreciate this. It is not less advantageous to plants that the pistil of one flower should, at any rate occasionally, be fertilised by the pollen from another. If, then, it is an advantage to flowers that they should be visited by insects, it is obvious that those flowers, which, either by their larger size, or brighter colour, or sweeter scent, or greater richness in honey, are most attractive to insects, would *entis paribus* have an advantage in the struggle for existence, and be most likely to perpetuate their race. In most flowers, indeed, the pistil is surrounded by a row of stamens, and it would at first sight seem a very simple matter that the pollen of the latter should fall on the former. This, in fact, does happen in many cases, but in others, from the structure of the flower, it is impossible. In these cases the transference of the pollen from one flower to another is effected principally either by the wind or by insects. Wind-fertilised flowers, however, as those of Birches, Poplars, and Grasses, are never brightly coloured, and are, indeed not popularly recognised as flowers. In our ordinary flowers, the transference of the pollen from one flower to another is effected by insects, and the colour, the scent, and the honey are the attractions by which the visits of insects are secured. That the beauty of flowers is useful in attracting insects is shown, moreover, by those genera in which we find species which vary very much in size and beauty. Thus we have two common species of Mallow (*Malva sylvestris* and *Malva rotundifolia*) which agree closely with one another in other respects, but of which the former is much larger than the latter, and Sir John showed that the former is dependent for its fertilisation on the visits of insects, while the latter is capable of fertilising itself. To show that this is no isolated case, he brought forward several other examples of the same fact, especially one very striking one in the genus *Geranium*. *Geranium pratense* is one of our larger species, and is nearly twice as large as *Geranium pyrenaicum*, which again is nearly twice as large as *G. molle*, while *G. molle* itself is considerably larger than *G. pusillum*. Now in *G. pratense* the pistil does not come to maturity till all the stamens have ripened and shed their pollen, and the flower, therefore, is absolutely dependent on insects for its fertilisation. In the second *G. pyrenaicum* some of the stamens have shed their pollen before the pistil is mature, but the visits of insects are, therefore, not absolutely necessary. In *G. molle* the pistil matures still earlier; while, lastly, in *G. pusillum* it matures even before the stamens. Here, therefore, we have a complete series, and the more the flower is dependent on insects the longer it has become. As already mentioned, the self-fertilisation of flowers is guarded against in various ways. Very frequently the stamens and pistils do not ripen at the same time. In some cases the pistil ripens before the stamens. Thus the *Aristolochia* has a flower which consists of a long tube with a narrow opening, closed by stiff hairs which point backwards, so that it has some resemblance to an eel trap. Small flies enter the tube in search of honey, but from the direction of the hairs find themselves imprisoned and cannot get out again. Gradually, however, the pistil passes maturity, the stamens ripen, and shed their pollen, by which the flies get thoroughly dusted. Then the hairs of the tube shrivel up, and release the prisoners, who fly away and carry the pollen to another flower. Again, in the common *Arum* we find a somewhat similar arrangement. The well-known green leaf encloses a central pillar, which supports a number of pistils near the base of another somewhat higher. Now, in this case, nothing would at first sight seem easier or more natural than that the pollen from the anthers should fall on and fertilise the pistils. This, however, is not what occurs. The pistils mature before the anthers, and, by the time the pollen is shed, have become incapable of fertilisation. It is impossible, therefore, that the plant should fertilise itself, nor can the pollen be carried by wind. When it is shed, it drops to the bottom of the tube, where it is so effectively sheltered that nothing short of a hurricane could dislodge it. Although the *Arum* is common enough, still the chances against any of the pollen so discharged being blown into the tube of another plant would be immense. As, however, in the *Aristolochia*, so also in the *Arum*, small insects, which, attracted by the showy central spadix, in the prospect of shelter or of honey, enter the tube when the stigmas are mature, find themselves imprisoned, as

the fringe of hairs which permitted their entrance prevents their returning. After a while the period of maturity of the stigmas is over and each secretes a drop of honey, thus repaying the insects for their captivity. The anthers then ripen and shed their pollen, which falls on and adheres to the insects. Then the hairs gradually shrivel up and liberate the insects, which emerge, carrying the pollen with them, so that those which then visit another plant can hardly fail to deposit some of it on the stigmas. Sometimes more than a hundred small flies will be found in a single *Arum*. In these two cases there is obviously a great advantage in the fact that the stigmas arrive at maturity before the anthers. Generally the advantage is the other way, and the stamens ripen before the pistil, as was shown by diagrams representing the Pink, Thyme, and other flowers. Of this the common so-called *Nasturtium* (*Tropaeolum*) is an interesting case. It produces much honey, which is situated in a long hollow spur. The flowers are much visited by insects, which thrust their proboscis down the spur in search of honey. When the flower first opens neither the stamens nor pistils are mature and they are all turned slightly downwards. Very soon, however, one of the stamens turn upwards, so as to stand just at the entrance to the spur, and in such a position that the under side of the proboscis of any insect wanting the honey almost inevitably rubs against it and carries off some of the pollen. One after another the eight stamens raise themselves and occupy this position, a process which occupies several days, after which they turn down again to the original position, and the pistil in its turn raises itself to the mouth of the tube. From this beautiful arrangement it is evident that the bees and other insects visiting this flower for the sake of the honey inevitably dust themselves with pollen from the younger flowers, and transfer it to the pistil of the older ones. In few flowers is the adaptation of the various parts to the visits of insects more clearly and beautifully shown than in the common white Dead Nettle (*Lamium album*). The honey occupies the lower contracted portion of the tube, and is protected from the rain by an arched upper lip and by a thick ring of hairs. Above the narrower lower portion the tube expands and throws out a broad lip, which serves as an alighting place for large bees, while the length of the narrow tube prevents the smaller insects from obtaining access to the honey, which would be injurious to the flower, as they would remove the source of attraction for the bees, without effecting the object in view. At the base of the tube, moreover, there is a ring of hairs, which prevents small insects from creeping down the tube, and so getting at the honey. *Lamium*, in fact, like so many of our other wild flowers, is especially adapted for humble bees; they light on the lower lip, which projects at the side, so as to afford them a leverage by means of which they may press the proboscis down the tube to the honey, while, on the other hand, the arched upper lip in its size, form, and position, is admirably adapted not only as a protection against rain, but also to prevent the anthers and pistil from yielding too easily to the pressure of the insect, and thus to ensure that it presses the pollen it has brought from other flowers against the pistil, and, on the other hand, carries away a fresh supply from the anthers. From the position of the pistil, which hangs down below the anthers, the bee comes in contact with the former before touching the latter, and, consequently, generally deposits upon the stigma pollen from another flower. The small processes on each side of the lower lip are the rudiments of the lateral leaves with which the ancestors of the *Lamium* were provided. Thus, then, we can see how every part of this flower is either, like the size and shape of the arched upper lip, the relative position of the pistils and anthers, the length and narrowness of the tube, the size and position of the lower lip, the ring of hairs, and the honey, adapted to ensure the transference by bees of pollen from one another, or, like the minute lateral points, is an inheritance from more highly developed organs of ancestors. Sir John Lubbock then called attention to certain species of the genus *Salvia*, a form allied to the Dead Nettle, but in which the back of the bee does not come in contact with its arched upper lips, and consequently does not touch the anthers in their natural position. They possess, however, a very curious tinge point, so arranged that the proboscis of the bee, in passing down the tube, presses one arm of a lever, and thus brings the other, which bears the anther down on to the back of the bee. The common Heaths (*Erica tetralix* and *Erica cinerea*), offer us another very ingenious arrangement. In *Erica tetralix* (the cross-leaved Heath), for instance, the flower is in the form of a bell, which hangs with its mouth downwards, and is almost closed by the pistil which represents the clapper. The stamens are eight in number, and each terminates in two cells, which diverge slightly, and have at their lower end an oval opening; but, though this opening is at the lower end of the anther cells, the pollen cannot fall out, because each cell, just where the opening is situated, touches the next anther cell, and the series of anthers thus form a circle surrounding the pistil, and not far from the centre of the bell. Each anther cell

also sends out a long process, which thus form a series of spokes standing out from the circle of anthers. Under these circumstances, a bee endeavouring to suck the honey from the nectary cannot fail, firstly, to bring its head in contact with the viscid stigma, and thus to deposit upon it any pollen derived from a previous visit; and, secondly, in thrusting its proboscis up the bell, it inevitably comes in contact with one of the anther processes, which acts like a lever, and dislocates the whole chain of anther cells, when a shower of pollen falls from the open cells on the head of the bee. In many cases the effect of the colouring and scent is greatly enhanced by the association of several flowers in one bunch or raceme, as, for instance, in the wild Hyacinth, the Lilac, and other familiar instances in the great family of Umbelliferae. This arrangement is still further taken advantage of, as in the common wild Chervil (*Cherophyllum sylvestre*). In this group the honey is not, as in the flowers just described, situated at the bottom of a tube, but is exposed, and is therefore accessible to a great variety of small insects. The union of the florets into a head is, moreover, not only of advantage in rendering them more conspicuous, but also effects a considerable saving of time, as it enables the insects to visit a given number of flowers more rapidly, and, consequently, renders their fertilisation more certain than if they had stood singly. The self-fertilisation which, in small flowers such as these, would otherwise naturally occur, is provided against by the fact that the stamens ripen before the pistil, and the latter is not mature until the former have shed their pollen; so that the flowers cannot, therefore, fertilise themselves in some cases, as, for instance in Myrrhis. The flowers of one head are all, firstly, in the male condition, and subsequently in that with mature stigmas, none of them arriving at the second stage until they have all passed through the first. It will be seen that in these florets the petals are not symmetrical, the outer ones being considerably larger than the others, and in many Umbellifers the florets themselves, on the outer edge of the bunch, or umbel, are considerably larger than the minor ones. This distinction is carried still further in the Composite, where also the florets are so closely packed that the whole umbel is commonly—though, of course, incorrectly—spoken of as a flower. For instance, the heads of the common Daisy are not, strictly speaking, flowers, but bunches of flowers closely packed together on a common base or receptacle. The advantages of this arrangement are, first, that the flowers become much more conspicuous than would be the case if they were arranged singly; secondly, that the facility with which the honey is obtained renders them more attractive to insects; thirdly, that the visits of the insects are more likely to be effectual, since the chances are that an insect which once alights touches several, if not many, florets. In the large white Daisy the flower-heads consist of an outer row of female florets in which the tubular corolla terminates on the outer side in a white leaf or ray, which, doubtless, is useful in making the flower conspicuous. The minor florets are also tubular, but are small, yellow, and without rays; each of these florets is furnished with stamens as well as a pistil. The stamens are united on their minor sides, so as to form a closed tube, within which the pistil lies; they ripen before the pistil, and the pollen is discharged into the upper end of the tube above the head of the pistil. When the flower opens the pollen is already ripe, and fills the upper part of the stamen tubes. The pistil, however, also continues to elongate, and at length pushes the pollen against the upper end of the tube, which gives way, and thus the pollen is forced out of the tube. The pistil itself terminates in two branches, which at first are pressed closely to one another, each terminating in a brush of hairs; the style elongates, the brush of hair sweeps the pollen cleanly out of the tube, and it is then soon removed by insects. When the pistil has attained its full length the two branches open and curve downwards, so as to expose the stigmatic surfaces, which had previously been pressed closely to one another, and thus protected from the action of the pollen. From this arrangement it is obvious that any insect alighting on the flower-head of the Chrysanthemum would dust its under side with the pollen of the younger flowers, which then could not fail to be brought into contact with the stigmatic surfaces of the older ones. As the expansion of the flowers begins at the outside, and thence extends to the centre, it is plain that the pollen of any given flower cannot be used to fertilise one situated on its inner side; consequently, if the outer row of florets produced pollen, it would, in the great majority of cases, be wasted. These florets, therefore, do not produce pollen, while the saving thus effected enables them to produce a larger corolla. It is also interesting to observe that, in these outer flowers, the branches of the pistil do not possess the terminal brush of hair, which, in the absence of pollen, would be useless. In other Composites, as in the Marigold, while the ray flowers produce no pollen, the disk flowers develop no stigmas. In this case the pistil of the ray flower does not require or possess the terminal brush of hairs, as there is no pollen to be swept out. The

central flowers, on the other hand, though they develop no stigmas, require a pistil in order to force the pollen out of the anther tube; hence, the pistil is present. This alteration of the function of the pistil is extremely curious. In the flowers hitherto described, while the several species offer the most diverse arrangements, we have met with no differences within the limits of the same species, excepting those dependent upon sex. He then proceeded to call attention to some cases in which the same species possess flowers of two or more kinds, which sometimes, as in the Violet, are adapted to different conditions, but more frequently are so constituted as to ensure cross fertilisation. In some of the Violets—viz., *odorata canina*, &c.—besides the blue flowers with which we are all so familiar, but which produce very little seed, there are other autumnal flowers, almost without petals and stamens, in which the seeds are produced. As these curious flowers, however, have no relation to our present subject, said the speaker, I shall not now dwell on them. The genus *Primula* offers a most interesting case of dimorphism. The Cowslip and the Primrose resemble one another in many respects, though the honey they secrete must be very different; for while the Cowslip is habitually fertilised during the day by bumble bees, this is not the case with the Primrose, which, in Mr. Darwin's opinion, is fertilised almost exclusively by moths. If a number of specimens of Primroses or of Cowslips are examined, we shall find that about half of them have the pistil at the top of the tube and the stamens half-way down, while the other half have, on the contrary, the stamens at the top of the tube and the pistil half-way down. An insect, therefore, thrusting its proboscis down a Primrose of the long-styled form would dust its proboscis at a part which, when it visited a short-styled flower would come just opposite the head of the pistil, and could not fail to deposit some of the pollen on the stigma conversely. An insect visiting a short-styled plant would dust its proboscis at a part further from the tip, and which, when it subsequently visited a long-styled flower, would again come just opposite to the head of the pistil; hence we see that by this beautiful arrangement, insects will carry the pollen of the long-styled form to the short-styled form, and *vice versa*. The genus *Lythrum* is a still more remarkable case, as there are no less than three distinct forms belonging to one species. In the course of his lecture, Sir John Lubbock described the arrangement and contrivances by which fertilisation was secured in many other plants, the most curious of which, however—such, for instance, as those in the various species of Orchids—could not be made intelligible without the aid of figures to replace the diagrams by which the lecture was illustrated. He also described the points in which the anatomy of insects has been modified to adapt them to the fertilisation of flowers, dwelling especially on the structure of the mouth and of the legs. He also referred to one other peculiarity of flowers, which is explained if we take this view of the relations of insects to flowers. Many flowers close their petals during rain, which is obviously an advantage, since it prevents the honey from being spoilt or washed away. Everybody, however, has observed that even in fine weather certain flowers close at particular hours. This habit of going to sleep is surely very curious. Why should flowers do so? In animals we can understand it; they are tired and require rest. But why should flowers do so? Why should some flowers do so and not others? Moreover, different flowers keep different hours. The Daisy opens at sunrise and closes at sunset, whence its name, Day's-eye; the Dandelion (*Leontodon taraxacum*) opens at seven and closes at five; *Arenaria rubra* is open from nine to three; Ear Hawkweed (*Hieracium pilosella*) is said to wake at eight and go to sleep at two; the scarlet Pimpernel (*Anagallis arvensis*) to wake at seven and close soon after two; while *Tropaeogon pratensis* opens at four in the morning, and closes just before twelve, whence its English name, "John-go-to-bed-at-Noon." Farmer boys and labourers are said to regulate their dinner hour by it. Other flowers, on the contrary, open in the evening. Now, it is obvious that flowers which are fertilised by night-flying insects would derive no advantage from being open by day; on the other hand, those which are fertilised by bees would gain nothing by being open at night—nay, it would be a distinct disadvantage, because it would render them liable to be robbed of their honey and pollen by insects which were not capable of fertilising them. He believed, then, that the closing of flowers had reference to the habits of insects. He observed, also, in support of this, that wind-fertilised flowers never sleep, that some of those flowers which attract insects by smell emit their scent at particular hours; thus, *Hesperis matronalis* and *Lychnis veapertina* smell in the evening, and *Orchis bifolia* is particularly sweet at night. He had been, he said, good-humouredly accused of attacking the little busy bee, because he had attempted to show that it does not possess all the high qualities which have been popularly and poetically ascribed to it; but, if scientific observations do not altogether support the intellectual eminence which has been ascribed to bees, they have made known to us, in the economy of the hive,

many various peculiarities which no poet had ever dreamt of, and have shown that bees and other insects have an importance as regards flowers which had been previously unsuspected. To these we owe the beauties of our gardens and the sweetness of our fields. To them flowers owe their scent and colour—nay, their very existence in its present form. Not only have their brilliant colours, the sweet scent, and the honey of the flowers been gradually developed by unconscious selection of insects; but the very arrangement of the colours, the circular bands, and radiating lines, the form, size, and position of the petals, the arrangement of the stamens and pistil are all arranged with reference to the visits of insects, and in such a manner as to ensure the grand object which renders these visits necessary. In conclusion, he observed that, while he had attempted to point out relations which exist between insects and some of our common wild flowers, the whole subject is one which will repay most careful attention; for, as Müller has very truly said, there is no single species the whole history of which is yet by any means thoroughly known to us.

The lecture, of which the above is a mere summary, was received throughout with great applause, the colours of the diagrams being admirably brought out by the action of the electric light.

Carnivorous Plants.

Dr. Hooker offered some interesting observations on this subject, which is one to which we have previously fully alluded. Various observers, he said, have described, with more or less accuracy, the habits of such vegetable sportsmen as the Sundew, the Venus's Fly-trap, and the Pitcher plants, but few have inquired into their motives; and the views of those who have most accurately appreciated these have not met with that general acceptance which they deserved. Quite recently the subject has acquired a new interest, from the researches of Mr. Darwin into the phenomena which accompany the placing albuminous substances on the leaves of *Drosera* and *Pinguicula*, and which, in the opinion of a very eminent physiologist, prove, in the case of *Dionaea*, this plant digests exactly the same substance, and in exactly the same way, that the human stomach does. With these researches Mr. Darwin is still actively engaged, and it has been with the view of rendering him such aid as my position and opportunities at Kew afforded me, that I have, under his instruction, examined some other carnivorous plants. The early history of the subject was then explained up to the date of Mr. Darwin's investigation, the conclusions arrived at being that in the small family of the *Droseraceae* we have plants which, in the first place, capture animals for purposes of food; and, in the second, digest and dissolve them by means of a fluid which is poured out for the purpose; and, thirdly, absorb the solution of animal matter which is so produced. The very curious group of Pitcher plants called *Sarracenias* next engaged attention. This genus consists of eight species, all similar in habit, and all natives of the eastern States of North America, where they are found more especially in bogs, and even in places covered with shallow water. Their leaves, which give them a character entirely their own, are pitcher-shaped and trumpet-like, and are collected in tufts springing immediately from the ground; and they send up, at the flowering season, one or more slender stems bearing each a solitary flower. This has a singular aspect, due to a great extent to the umbrella-like expansion in which the style terminates; the shape of this, or perhaps of the whole flower, caused the first English settlers to give to the plant the name of "Side-saddle Flower." The first fact which was observed about the Pitchers was, that when they grew they contained water; the second, that they have a digestive process analogous to that which takes place in the stomach of an animal. It is evident that there are two very different types of Pitcher in *Sarracenia*, and an examination of the species shows that there must probably be three. These may be primarily classified into those with the mouth open and lid erect, and which, consequently, receive the rain water in more or less abundance; and those with the mouth closed by the lid, into which rain can hardly, if at all, find ingress. I cannot take leave of *Sarracenia* without a short notice of its near ally, *Darlingtonia*, a still more wonderful plant, an outlier of *Sarracenia* in geographical distribution, being found at an elevation of 5,000 feet on the Sierra Nevada of California, far west of any locality inhabited by *Sarracenia*. It has pitchers of two forms; one, peculiar to the infant state of the plant, consists of narrow, somewhat twisted, trumpet-shaped tubes, with very oblique open mouths, the dorsal lip of which is drawn out into a long, slender arching, scarlet hood, that hardly closes the mouth. The slight twist in the tube causes these mouths to point in various directions, and they entrap very small insects only. Before arriving at a state of maturity the plant bears much larger, sub-erect pitchers, also twisted, with the tip produced into a large inflated hood, that completely arches over a very small entrance to the cavity of the pitcher. A singular orange-red flabby two-lobed organ hangs from the end of the hood, right in front of the

entrance, which, as I have been informed by Professor Asa Gray, is smeared with honey on its inner surface. These pitchers are crammed with large insects, especially moths, which decompose in them, and result in a putrid mass. I have no information of water being found in its pitchers in its native country, but have myself found a slight acid secretion in the young states of both forms of pitcher. I might have added some additional cases to those I have dwelt upon. Probably, too, there are others still unknown to science, or whose habits have not yet been detected. But the problem that forces itself upon our attention is, how does it come to pass that these singular aberrations from the otherwise uniform order of vegetable nutrition, make their appearance in remote parts of the vegetable kingdom—why are they more frequent, and how were such extraordinary habits brought about, or contracted? These remarks will, I hope, lead you to see that though the processes of plant nutrition are, in general, extremely different from those of animals, and involve very simple compounds, yet that the protoplasm of plants is not absolutely prohibited from availing itself of food, such as that by which the protoplasm of animals is nourished, under which point of view these phenomena of carnivorous plants will find their place, as one more line in the continuity of Nature.

GARDENING FOR THE WEEK, AND AMATEUR'S CALENDAR.

The Flower Garden and Pleasure Grounds.
